The performance of the homemaker in feeding her family was considerably better than her knowledge (table 1). Homemakers who actually used each food group were more numerous than those who mentioned that it should be included in the meals or those who knew why. However, the food groups that were least well known were also least used. It would seem likely that for those groups where knowledge is necessary to appreciate the need for their inclusion in the family meals, inclusion in the 24-hour period was a matter of chance. Certain food groups, such as meat or meat substitutes, potatoes and other vegetables and fruits, and bread, flour, or cereals, are included in most meals conventionally. Probably butter (or fortified margarine) was used more than the figures indicate. Its use may not have been recalled. The figures presented for food usage in the previous 24 hours are almost identical, with minor variations, to those obtained in urban and rural Virginia and in two rural school districts in New York (2, 5).

Approximately 40 percent of both the Rochester and Syracuse homemakers included all seven food groups in their menus. This figure is lower than the 50 percent reported for urban Virginia (2) but similar to those reported for rural Virginia and rural New York (5).

Milk was the usual beverage served at most meals for children. But in substantially all of the homes, it was not the usual beverage for adults at any meal. Only 13 percent reported it as one of the adult beverage choices at breakfast, 33 to 44 percent at noon, and 31 percent at night.

A quantitative estimate of the adequacy of feeding practices with respect to four food groups is presented in table 3, with the bases used in evaluation of adequacy. In about one-fifth of the homes, less than half the suggested quantitative needs of the family were met for both the milk and citrus fruit groups. Again, practice is shown to be best with regard to usage of the meat and meat substitutes group.

Feeding practices did not vary so much with age and education as did levels of nutritional

Table 3. Percentages of households using adequate quantities of four given food groups during week

Food groups and adequacy levels	Rochester	Syracuse
<i>Milk</i>		
Less than 50 percent of need ¹ -----	20	19
At least 90 percent of need ¹ -----	34	31
<i>Eggs</i>		
One per day per person-----	39	33
Three or more per week per person--	98	98
<i>Meat, fish, or poultry</i>		
Two pounds per week per person over 10 years of age and one pound per week per child under 10 years of age-----	91	88
<i>Citrus fruit, tomato, or juices</i>		
Less than 50 percent of need ² -----	21	20
At least 90 percent of need ² -----	51	44

¹ Based on 1 pint per day per adult; 1 quart per day per child.

² Based on 1 serving of citrus fruit, or equivalent, per day per person.

knowledge. However, the younger and more educated homemakers adhered to better practices than did others. The level of educational attainment of those under study appeared to be the factor which was most consistently related to adequacy of performance in feeding the family. Income effects, as was true for their relationship with knowledge, were considerably less consistent and of smaller magnitude (6). Homemakers who reportedly had studied about what to eat apparently served better meals, both qualitatively and quantitatively, to their families than those who had not studied. The quality of breakfast patterns also improved with the factors which affected other feeding practices (6).

Knowledge and Action

Adequacy of dietary practices appeared to be related directly to the level of the homemaker's nutritional knowledge. As knowledge increased, so did the percentage of homemakers who included certain basic food groups in the 24-hour period (table 4), though differences were not large.

Repeated Pregnancy Wastage

By F. J. SCHOENECK, M.D.

PRECONCEPTIONAL study, treatment, and other medical attention for women whose pregnancies repeatedly end in misfortune have been accepted as a hope of reducing pregnancy wastage.

I have previously reported that a relatively small group of childbearing women account for a disproportionately high percentage of such wastage (1). Schlesinger and Allaway (2) state that the expectation of perinatal loss among women with a history of previous child loss was 2.7 times greater than among multiparous women without such loss. They concluded: "This trend toward further narrowing of the problem of perinatal loss points to the need for increased concentration of research and public health services on the vulnerable group of women who present a history of previous child loss." Randall, and associates (3) state: "When all other factors were disregarded and the outcome of the present pregnancy was compared among women with good obstetrical history and those with poor obstetrical history, abortion was found to have occurred 20 times more frequently when the previous obstetrical history was 'poor'."

Other articles of the general nature of those quoted are appearing in medical literature. The Syracuse Department of Health is reporting here the pregnancy outcomes of a group of

women selected specifically because of their poor obstetrical histories.

Pregnancy Outcomes

Clinical histories of these women have been gathered in the past 2 years from sources in and around Syracuse, N. Y. These sources included private records, completed prenatal clinic records, and histories obtained by public health nurses in patient interviews in connection with the department's current survey of pregnancy outcomes. The histories were collected primarily as "matching controls" to compare with the histories of patients attending our local prepregnancy treatment clinic.

The material consists of the obstetrical histories of 135 patients who had completed 653 pregnancies (an average of 4.8 pregnancies per patient). There were 3 sets of twins among the 135 patients; 126 (93.3 percent) were white and 9 (6.6 percent) were Negro; 75 (55.5 percent) were private patients, and 60 (44.5 percent) were service cases. Four patients, (2.9 percent) had definite Rh problems.

Outcomes of 653 pregnancies, according to the histories of these 135 patients, were:

	Number	Percent
Living babies.....	201	30.8
Term.....	141	21.6
Premature.....	60	9.2
Unsuccessful pregnancies.....	452	69.2
Postnatal deaths:		
Term.....	8	1.2
Premature.....	64	9.8
Stillborn.....	49	7.5
Abortions.....	324	49.6
Ectopic pregnancy.....	7	1.1

Dr. Schoeneck is the director of the bureau of maternal hygiene, Department of Health, Syracuse, N. Y.

food by homemakers are not reported here. However, it was found that family food shopping is done chiefly by homemakers, usually once a week. Most homemakers do not plan meals much ahead of time. More than 40 per cent do their planning on the day of the planned meal or at the "last moment." About two-thirds of the homemakers said they had a specific amount of money to spend for food each week or month. Ninety-two percent of the homemakers felt their families were getting all the needed foods.

One-third of the homemakers said they encountered some difficulty in planning, buying, or preparing food for their families. Two-thirds of those who said they had problems desired help. Means of obtaining variety and planning to suit all of the family's needs were mentioned most frequently. Budgeting, quick menus, food habits, and special diets also were cited as problems in the order named. Younger, better educated homemakers expressed the need for help with more problems than did others.

The homemaker ranked magazines and newspapers as the primary source for information on what to feed the family. Mothers and relatives were the persons most often mentioned as sources. Of professional persons, the greatest number of homemakers felt the physician had given them the most information. Homemakers used recipes and information on food preparation more extensively than other kinds of material supplied. Next most frequently used was information on meal planning and the components of a balanced diet.

Results of the study have been reported to public health, nutrition, education, and extension groups in Rochester, Syracuse, and elsewhere. These have included regional public health and dietetic associations; nutrition committees; nutrition workshops for health, education, and welfare personnel; and workshops for school lunch personnel, for home economics teachers, and for extension workers.

Cancer in Iowa

Of each 100,000 Iowa residents, 509 persons had cancer during 1950; 347 of these were first diagnosed during the year. Females had a slightly higher incidence rate than males. When adjustments are made for the age distribution of the population, the Iowa incidence rate for all sites excluding skin, 253, was 12 and 9 percent below the respective figures for the combined 10 cities (286) and the 4 northern cities (277) recently surveyed by the National Cancer Institute of the Public Health Service. Much of this differential can be attributed to a lower rate in rural Iowa. The rate for urban Iowa agreed well with that reported for the four northern cities.

In Iowa, 76 percent of the newly diagnosed cancer cases were confirmed microscopically. This was essentially the same as the combined figure from surveys of the 10 urban areas. The urban-rural differential in this respect was small—77 percent contrasted to 73 percent—which suggested about equal reliability of diagnoses in the two population groups. In view of the proportion of cases with microscopic confirmation in Iowa, it may be noted that most comparisons and inferences drawn from the Iowa data remained essentially unchanged, whether based on total newly diagnosed cases or solely on those meeting exacting diagnostic criteria.

Among Iowa males, cancer occurred most frequently in the digestive system, skin, genital organs, buccal cavity, and respiratory system. Among females, the order was genital organs, breast, digestive system, and skin. The leading specific sites for males were prostate, stomach, large intestine, and lung; for females, breast, cervix, and large intestine.

Incidence rates in the urban population were higher than in the rural population for such primary sites as lung, larynx, and cervix. Several lines of indirect evidence, based partly

on examination of the data for internal consistency, support the hypothesis that these differences are real. There was little difference in the incidence of cancer of the corpus uteri, breast, prostate, and digestive system among urban and rural residents.

Public Health

MONOGRAPH

No. 37

The accompanying summary covers the principal findings presented in Public Health Monograph No. 37, published concurrently with this issue of Public Health Reports. The authors are with the National Cancer Institute, National Institutes of Health, Public Health Service, Bethesda, Md., and the Iowa State Department of Health, Des Moines, Iowa.

Readers wishing the data in full may purchase copies of the monograph from the Superintendent of Documents, Government Printing Office, Washington 25, D. C. A limited number of free copies are available to official agencies and others directly concerned on specific request to the Public Inquiries Branch of the Public Health Service. Copies will be found also in the libraries of professional schools and of the major universities and in selected public libraries.

Haenszel, William, Marcus, Samuel C., and Zimmerer, Edmund G.: Cancer morbidity in urban and rural Iowa. Public Health Monograph No. 37 (Public Health Service Publication No. 462). 85 pages. Illustrated. U. S. Government Printing Office, Washington, D. C., 1956. Price 20 cents.

Of the total of 653 pregnancies, 12 babies (1.8 percent) had congenital anomalies. Of 201 living children, 3 (1.4 percent) had retro-lental fibroplasia.

Unfortunately, the information available is not sufficiently complete to allow epidemiological analysis. Such an approach to each patient might establish whether these women have more in common than their obstetrical history. Identification of such common factors is a step toward their elimination or control.

There is some question in our minds about the complete reliability of the retrospective observations of these women, but we are gathering data from our continuing study which we hope will provide clues for further preventive and remedial action.

Reduction in infant loss and salvage of babies from unusual pregnancies have certainly not kept pace with the reduction in maternal mortalities. Pregnancy salvage for the minority of unsuccessful patients is a challenge to the public health-obstetric-pediatric team.

Comments

We subscribe to the current methods of correction as exemplified by the present programs in New York City, Chicago, and New York State, outlined by Yankauer (4) and by various other professional groups and health agencies. In general these programs aim at improving care during the prenatal, labor, and delivery periods, and pediatric care.

Our previous studies in the field of unsuccessful pregnancies would seem to indicate that fetal salvage is essentially an obstetrical problem (5). Hughes (6) in speaking of fetal salvage states: "Although we believe that all these standards should be carried out carefully; that prenatal care should be improved; that pediatric care after birth should be made bet-

ter, we are of the opinion that in order to reduce the infant death rate to a new low in this country, we must take a more specific approach to the problem."

One example of a specific approach is the preconceptional study and prophylactic treatment of women with a history of repeated unsuccessful pregnancies, as carried out by Hughes and his group in Syracuse. Many other types of study are necessary to cope with the obstetrical complications so often associated with abortion or fetal loss.

Public health activities can play important roles in such a program. As an example, in Syracuse we are trying to find women who have or probably will have unsuccessful obstetrical experiences so that they may be studied and perhaps helped to bear healthy babies.

Women with habitual pregnancy loss should be recognized as having specific problems worthy of consideration from all interested medical groups.

Does the nitrification of soil contribute to methemoglobinemia, one cause of infant mortality? A survey of soil and water in southern Minnesota explored the possible relationship.

Soil Nitrification and Nitrates in Waters

By EDWIN L. SCHMIDT, Ph.D.

VERY young infants, usually less than 2 months old, may acquire methemoglobinemia as a result of ingesting water high in nitrates. The ingested nitrate may oxidize a portion of the hemoglobin to methemoglobin with consequent loss in oxygen transport and oxygen exchange in the blood; if severe, the anoxemia may produce serious effects, and death may occur.

Cases of methemoglobinemia induced by well waters high in nitrates have been reported principally in the midwestern United States and the central Provinces of Canada (1, 2). Although the high nitrate content of most of the wells studied apparently was associated with nearby sources of pollution, the origin of the nitrates that accumulate in ground waters was not always clear (2). Several writers have suggested that nitrate formation in normal agricultural soils may contribute significantly to nitrate accumulation in rural well waters (1, 3-5). This suggestion merits further consideration, since the peculiar geographic distribution of the disease in the United States corresponds roughly to the belt of highly productive Chernozem and Prairie soils.

Nitrates are found in soils as a result of the activities of the soil microflora. Nitrogen reaches the soils principally in organic form as

a part of plant and animal residues, and in this form it is subject to attack by a large and diversified group of soil micro-organisms. As the result of microbial action the nitrogen added originally in organic complexes is transformed into new organic combination as a constituent of microbial protoplasts, and the excess beyond cell needs is converted to the inorganic ammonium form. A first prerequisite of high nitrate production is the occurrence of nitrogen in the ammonium form.

Ammonium nitrogen is transformed rather rapidly under appropriate soil conditions by the activity of the specific autotrophic nitrifying bacteria of the genera *Nitrosomonas* and *Nitrobacter*. These organisms derive their energy, respectively, from the oxidation of ammonium to nitrite and the oxidation of nitrite to nitrate. Many soil factors influence the activity of the nitrifiers, but it is well established that the most fertile soils generally promote the most active nitrification.

To obtain information regarding the possible relationship between nitrate accumulation in waters and nitrate production in soils associated with those waters, a survey of soil nitrification was undertaken in the methemoglobinemia region of Minnesota in 1951. This survey was made possible by a grant from the Minnesota Department of Health.

Organization of the Survey

The areas included in the survey were located in Renville, Nobles, Rock, and Mower Counties

Dr. Schmidt is associate professor in the department of bacteriology and immunology and in the department of soils, University of Minnesota.

Excluding cancers of the lymphatic tissue and the hematopoietic system, two-thirds of the newly diagnosed cancers were localized at time of diagnosis. One of four had spread to adjacent tissue or regional lymph nodes, and 1 of 10 had metastasized to remote tissues. More cancers in males were diagnosed while localized (71 percent, excluding lymphatic tissue and hematopoietic system) than in females (63 percent). This resulted not from a systematic sex differential for certain sites but from the preponderance of breast cancer among women, for which the probability of early diagnosis has been relatively poor. The greatest variable in stage at diagnosis was shown with regard to primary site. To illustrate, only 49 percent of cancers involving the digestive system were diagnosed while localized compared to 86 percent for buccal cavity. In general, the proportion of localized cases was higher for the more accessible sites.

Of every 100 residents with newly diagnosed cancer in Iowa, 75 were alive 6 months after diagnosis, and 66 were still alive after 1 year. There was no difference in the urban and rural experience with respect to survival. Stage at diagnosis had the most pronounced effect on survival rates. Of cancer cases diagnosed while localized, 81 percent survived 12 months as contrasted to 45 percent of those with regional involvement and 27 percent, with remote metastasis. Uterus and large intestine are among the sites exhibiting the greatest range in survival rates for cases in early and late stages. Survival rates for certain sites, such as pancreas and lung, are extremely poor even when diagnosed early.

With respect to primary site of cancer, agreement between data on medical records and on death certificates was good. For most primary sites, comparisons between urban and rural areas based on incidence and mortality rates were in close agreement.

Morbidity data reported from Denmark generally show findings similar to those from Iowa with respect to urban-rural differentials. Both showed substantial differentials in incidence for all sites combined (exclusive of skin, lymphatic tissue, and hematopoietic system). For lung and bronchus, both sets of data exhibited a much more pronounced urban-rural differen-

tial among males. They agreed on two distinct urban-rural patterns for cervix and corpus uteri. Neither the Danish nor Iowa data supported impressions of higher skin cancer incidence rates among rural populations as reported in medical textbooks.

The age and sex patterns of cancer incidence in Iowa conformed generally to those reported from morbidity surveys elsewhere. Incidence of cancer increased rapidly during late adult life for both sexes. Although female rates for all ages combined exceeded those for males, females experienced lower rates at ages under 10 and over 65.

Although most cancers tend to appear in late adult life, some forms occur relatively frequently among young people. Less than 5 percent of the newly diagnosed cases in Iowa occurred among persons under 35, whereas one-fourth of cancers of the brain and endocrine glands, not elsewhere classified, and one-fifth of those in the skeleton and hematopoietic system were in this age group.

Carcinoma constituted 86 percent of the newly diagnosed, microscopically confirmed cases of cancer in Iowa, a figure in close agreement with that from the 10-city morbidity surveys. Within Iowa there was no difference in this respect between urban and rural residents. Adenocarcinoma was more frequent among females, whereas epidermoid carcinoma was the leading type among males. One site—breast—accounted for much of the preponderance of adenocarcinomas among females. Leukemia was the most frequent histological type encountered at ages under 15. Thereafter, carcinomas became increasingly predominant.

During 1950, 6,979 cancer patients were hospitalized for a total of 159,316 days, an average of 23 days per patient. The average length of stay did not differ for patients from urban and rural areas. Cancers of the digestive system alone accounted for about one-third of the total hospital days. Of the newly diagnosed resident cases, 59.2 percent were hospitalized within 1 year after diagnosis. The first course of hospitalization for newly diagnosed cases accounted roughly for three-fifths of the total hospital days devoted to cancer treatment. The average duration of first hospitalization was 20 days.

considered in connection with certain conditions at the time of sampling. The first sampling in Renville County, in early July, followed a period of about 3 weeks of abnormally heavy rainfall. The excess rainfall had caused standing water in some fields, drowned-out areas in corn, alfalfa, and bean fields, and a water table within 30 inches of the surface in many places. At the time of the second sampling, late in August, more normal conditions of rainfall prevailed. Both rainfall and crop development conditions were altered markedly between sampling periods. The nitrate content of the water supplies was lower and that of the surface soils was higher at the time of the second sampling. It is likely that the high rainfall prior to the initial sampling leached large quantities of nitrates from the surface soil at a stage of crop development that made relatively small nutritional demands on the nitrates of the soil. Much of the nitrate washed from the surface soil might well have contributed to that of the ground water supply.

Similar variations with rainfall conditions were observed in Rock and Nobles Counties, although the nitrate concentrations fluctuated less. In these counties, initial samples were taken after several weeks of near normal weather, whereas the second samples were taken soon after a short period of heavy rainfall. The variation noted in the nitrate content of the same well water is in agreement with the observations of Siemens and Mallett (9).

The data concerning the relationship between the nitrifying capacity of the soils and the nitrate concentration of the water supplies near those soils are summarized in table 4. The water supplies are grouped according to their nitrate content.

Soils that were obviously contaminated with organic nitrogen by livestock had the highest nitrifying capacities. These soils represented barnyards or the feeding lots so common in southwestern Minnesota or areas that so closely adjoined them as to be influenced by the organic nitrogen present. As can be seen in table

Table 1. Nitrate content of water supplies and of nearby soils in Renville County, Minn.

of southwestern and south central Minnesota. The first three of these are among the counties in the State that reported the largest number of methemoglobinemia cases in the period 1947-49, according to the report of Rosenfield and Huston (5). Mower County is about 100 miles east of the principal methemoglobinemia region described in that report.

Starting points for studies in each county were selected on the basis of records on file at the Minnesota Department of Health. Each initial site was a farm that, according to the health department's field studies of infant methemoglobinemia, had a high nitrate water supply. Following the survey of the initial site, additional sites in the same section and in adjoining sections were examined.

The survey of a given site centered about the water supplies of that site. In addition to farm wells, field tile drains that were carrying water, rural school wells, springs, and streams in the vicinity were included in the survey. A qualitative test for nitrate, with diphenylamine solution, was made at the site. Information was sought concerning such features as location, depth, construction, and use of farm wells; topography and surface drainage; the location of waste organic nitrogen accumulations; and land use practices. A sample from each water supply was collected for subsequent laboratory analysis. (Laboratory analysis of water samples was done by the Minnesota Department of Health.)

Soils in the vicinity of the water supplies were observed for topography and land use. Sites for sampling were selected so as to reflect the variations in soils. The usual practice was to obtain samples within a 50-foot radius of the water supply and to supplement these with samples collected from the various soils 100 to 500 feet from the water supply. Composite samples of surface soil, made up of from 4 to 6 subsamples, were taken from the 0- to 6-inch soil layer, and corresponding subsoil samples were taken at a depth of 30 to 36 inches with a soil auger.

The nitrate content of the soil and water samples returned to the laboratory was determined quantitatively by standard methods using phenoldisulfonic acid (6, 7). (Nitrate is

measured and reported as parts per million nitrate nitrogen, or $\text{NO}_3\text{-N}$, which denotes the amount of nitrate in terms of its nitrogen.) The nitrifying capacity of each surface soil sample was determined by conventional methods of soil microbiology (8). Each soil was rated low, medium, high, or very high in nitrifying capacity on the basis of the quantity of nitrate produced by 100 gm. of soil incubated in the presence and in the absence of added ammonium nitrogen during a 6-week period. Solution culture studies using each surface soil as an inoculum provided additional data in rating the nitrifying capacity of each soil. Soils rated low produced less than 3 p.p.m. nitrate nitrogen during incubation for 6 weeks in the absence of added ammonium nitrogen and less than 35 p.p.m. nitrate nitrogen when 30 mg. ammonium nitrogen had been added. Soils rated very high produced more than 100 p.p.m. nitrate nitrogen without added nitrogen and more than 700 p.p.m. nitrate nitrogen in the presence of added nitrogen.

Results and Discussion

Almost all of the wells examined were of dug or bored construction and were relatively shallow, generally 15 to 50 feet deep. Exceptions to these characteristics are noted in the tables.

The concentrations of nitrate found in the waters sampled and in soils in the vicinity of the water supply are listed in tables 1, 2, and 3. (Data for soil samples taken beyond 50 feet from the water supply are not given, since these samples numbered only 7 for surface soil and 6 for subsoil.) The nitrate content of the soils varied greatly within a short distance, and the same soil varied considerably with the time of sampling. Nitrates in the surface soil maintained no constant relation to the nitrates in the parent material (subsoil samples) of that soil. There was no relation between the nitrate content of the water and that of the soils at the time of sampling. The variations in soil nitrate content are to be expected, since the nitrates that are produced in the surface soil are subject to leaching by rainfall and to utilization by microorganisms and higher plants.

The data on nitrate concentrations must be

Table 4. Nitrate content of water supplies in relation to their location and to the land use and nitrifying capacity of nearby soils

¹ Location of the water supply was evaluated on the site. Sites classed as "poor" were located within a hundred feet of obvious concentrations of organic nitrogen. Those classed as "good" were sites well removed from any concentrations of organic nitrogen. Those sites classed as "questionable" usually were within several hundred feet of manure piles or barnyards. ² Drilled well, 130 feet deep. ³ Drilled well, 260 feet deep.

4, water supplies with the highest concentrations of nitrate were located near soils of very high nitrifying capacity. At all but one of the sites in this group, the very high nitrifying capacity of at least one soil near each water

supply was due to a concentration of organic nitrogen. At that one, site 8, no effect of organic nitrogen contamination was readily apparent, although a hog-feeding area within 150 feet of the water supply existed a few years

cultivation near the very high nitrate waters were generally much lower in nitrifying capacity, but many of the normal field soils exhibited high nitrifying capacity despite the absence of abnormal additions of organic nitrogen. Such field soils were associated with subsoil drainage waters of up to 18 p.p.m. nitrate nitrogen and well waters of up to 35 p.p.m. nitrate nitrogen.

The rich soils of southwestern Minnesota present nearly ideal conditions for soil nitrification, limited normally by the release of ammonium nitrogen from the soil organic matter. Pollution of these soils with nitrogenous wastes will provide an excess of ammonium nitrogen and result in extremely high nitrate production. It seems possible that such soils of very high nitrifying capacity may sometimes contribute to the nitrate content of water supplies ordinarily considered to be satisfactorily located. Further study of the relation of nitrification to the accumulation of nitrate in waters will be necessary before any definite conclusions can be drawn.

Fluoridation of Public Water Supplies

The Supreme Court of Oregon on January 11, 1956, in the case of *Baer v. City of Bend*, confirmed the decree of the circuit court which had sustained a demurrer to the complaint brought to enjoin city officials from fluoridating the Bend water supply.

The plaintiff contended that fluoridation would deprive him of his liberty without due process of law secured by the 14th amendment and encroach on his freedom of religion secured against Federal intrusion by the first amendment and similarly secured against State intrusion by the 14th amendment. The court, noting the various cases and other authorities (and the express concession of the plaintiff that dental health is a proper field for the exercise of State authority), held that the fluoridation measure of the city of Bend was a reasonable law for the protection of the public health and did not violate any religious or other liberties guaranteed by the Constitution.

ago. Sites 6 and 17 illustrate that large concentrations of organic nitrogen in the soil adjoining a well are not necessarily reflected in a high nitrate content for that well.

Of primary interest in this study was the question of whether or not the normal field soils—the agricultural soils uncontaminated by heavy additions of organic nitrogen—might contribute to the nitrates that accumulate in the well waters of the methemoglobinemia region. The data in table 4 throw some light on this question.

The nitrifying capacity of soils other than those designated as "barnyard" ranged from low to very high. Only one of these soils, at site 8, was rated very high, and, as has already been noted, it is possible that this soil was contaminated by concentrations of organic nitrogen formerly in the vicinity. The soils of the region of Minnesota surveyed were highly productive when first placed in cultivation less than a hundred years ago. The high native fertility was due in large part to the high organic content of the soils. The effect of continued cultivation involving both good and bad land-management practices would be expected to influence the nitrifying capacities of the soils by virtue of influencing the kind and quantity of organic nitrogen present. Many of the normal soils examined demonstrated a high nitrifying capacity. The laboratory measurements of soil reaction and the field observations on the organic matter content and texture of the soils further support the conclusion that many of the soils of the region are capable of producing substantial quantities of nitrates. The addition to such soils of organic nitrogen in the form of manure fertilizers or accumulated waste from livestock will result in the very high nitrifying capacity found in the barnyard soils.

The nitrate content of certain of the waters associated with the normal field soils of medium to high nitrifying capacity is of marked interest. The data in table 4 for field tile drains reveal that drainage waters directly influenced by soil nitrification contained as much as 18 p.p.m. nitrate nitrogen. At site 5, where the direct contribution of soil nitrification was more difficult to assess, a well contained 35 p.p.m. nitrate nitrogen despite its location far from any con-

centrations of organic nitrogen. This well served only a home, and no farm buildings were within one-half mile. The cultivated field adjoining the well had a high nitrifying capacity, and it is considered likely that soil nitrification was the important factor concerned in the nitrate content of the well water at the time of the initial sampling.

None of the samples of stream or ditch water examined showed evidence of nitrate accumulation. The streams proved to be a poor index of generalized nitrate production in the areas sampled probably because the heavy algal growth in the streams kept the supply of available nitrogen low.

Summary and Conclusions

In connection with a survey to investigate the possible relation between nitrate production in soil and nitrate concentration in waters, data on 39 water supplies from 26 sites in 4 counties of Minnesota were obtained. Samples of 59 surface soils and 50 subsurface soils associated with these waters were studied in the laboratory for nitrate content. The surface soils were also studied for capacity to produce nitrates. Laboratory data on the water and soil samples were interpreted in the light of field observations.

The 16 water supplies that were sampled a second time during the summer gave evidence that the nitrate content of the water supplies fluctuated significantly during a 5- to 6-week period. These fluctuations were considered to be due largely to soil leaching associated with the rainfall distribution. Changes in the nitrate content of the surface soils correlated well with changes in the nitrate content of the water supplies. The nitrifying capacities of the soils remained essentially constant for the two samplings.

Soils obviously contaminated with organic nitrogen by livestock had the highest nitrifying capacities. The water supplies with the highest concentrations of nitrate (75 to 130 p.p.m.) were located near such soils. However, not all water supplies near contaminated soils had unusually high nitrate content.

Normal field soils in pastures, sod, or under

ventional divisions of knowledge concerned with individual behavior and human relations. The term thus makes it possible to exclude portions of political science, for instance, which are historical or philosophical and to include work going on in biology, geography, or law. Behavioral science cuts across the present organization of academic fields, but, in spite of this, coincides to a large extent with the subject matter of the traditional social sciences. The term social science is used throughout this paper except when the term behavioral science appears in a quotation or refers to the surveys.

The General Atmosphere

A reading of the behavioral science survey reports brings out a fundamental difference between the social sciences and the professions which can be expressed best as a difference in atmosphere or climate. There are three ways the difference in climate is expressed.

The first has to do with the premium placed on action in the professions as contrasted with development of knowledge in the social sciences.

In discussing the law school, the Harvard committee wrote, "The lawyer is attuned to the pressure for relatively immediate practical action. Many social scientists . . . resist being drawn into the vortex of action responsibility. . . . A social scientist . . . is likely to be interested primarily in the struggle for adequate noncontradictory generalizations. . . . The lawyer, on the other hand, is likely to be interested in general descriptive theory primarily insofar as it yields a clue to the solution of particular problems demanding action" (2a).

The subculture of all the professions is action oriented. The subculture of the social sciences is oriented toward analysis and explanation. This difference in climate has to be recognized in understanding the interaction processes of persons who come from the diverse backgrounds of science and practice.

Another difference in climate has to do with the deeply ingrained anti-bureaucratic, anti-hierarchical attitude of the social scientist and the ready adjustment of the professional to administrative policies and channels and to organizational requirements.

The mere conduct of the behavioral science surveys was seen as a threat by the social scientists. One social scientist at Harvard said, "The philosophy, in part, behind [these surveys] appears to be that science and scientific investigation can be channelized, organized, or even evaluated. Taking the latter, I know of no objective criteria for establishing whether a given project in basic research is 'good,' 'sensible,' 'useful,' 'worthwhile,' or even 'sane'" (2b).

Another one said, "I'm afraid you might come to some conclusions about the areas of potential growth in social science. I feel the area of potential growth lies exclusively in a genius having a new idea" (2b). This is typical of the academic individualism which prevails in the basic social sciences.

Viewed ideally, the university is a community of scholars who are roughly equal in authority and who are self-directive and self-disciplined (6). In contrast to this there is a comparative absence of the ideal of equalitarian anarchism in the professional schools. In the Harvard business school, the survey committee commented, "It is interesting to note that there have been no expressions of outright faculty opposition to central administration of the research program by the Division of Research" (2c). On the contrary, there were suggestions as to how the Division of Research, which presently "administers" the research program in the school and does not "direct" it, could be strengthened as a facilitating, coordinating, and planning unit.

In the Harvard Medical School the doctors found the anti-organizational bias of the social scientists puzzling and troubling. The physician is accustomed to being responsible to the patient and the hospital and to his colleagues and has difficulty accepting the social scientists' preference for a free scholarly approach.

The typical problem in a professional field is likely to cut across a number of scientific disciplines, and a group approach is frequently essential. Persons involved in establishing group research projects had better be sensitive, however, to the social scientist's resistances to having his work organized and made subject to an administrative hierarchy.

So much for climate. Additional differences

A review and appraisal of behavioral science self-surveys by five universities in the light of their value for medical social workers

The Behavioral Sciences and the Professions

By DAVID G. FRENCH, M.Sc.

THE CONTRIBUTION of the social sciences to the practicing professions has received increasing attention since World War II. That concentrated investment in mutual destruction produced, ironically, a major impetus to the science of human behavior and relationships. None of the "helping professions" today is without its contingent of members who advocate infusing professional knowledge and practice with social science theory and research.

There are, however, serious obstacles to effective collaborative work. The patterns evolved in the physical and biological sciences for relating basic and applied research do not apply directly to the field of human behavior and human relations. The social sciences are in about the 17th century in their development relative to the natural sciences. Yet the very fruitful division of labor between theory-focused and practice-focused research which has been evolved between the natural sciences and their related fields of application continues to challenge social scientists and social practitioners.

Mr. French is executive secretary of the Coordinating Committee on Social Welfare Research at the University of Michigan and lecturer in the School of Social Work at the university. The original of his paper was presented at the 82d annual forum of the National Conference of Social Work, San Francisco, May 29-June 3, 1955. The 1956 forum will be held in St. Louis, May 20-25.

A stimulating analysis of practice-science relationships in the social field is one of the outcomes of the surveys of the behavioral sciences conducted at Chicago, Harvard, Michigan, North Carolina, and Stanford Universities during 1953-54 under the sponsorship of the Ford Foundation. The surveys have been reported in administrative documents issued separately by the universities (1-5). Of particular interest to medical social workers and others in the health field is the survey conducted at Harvard. The Harvard Survey Committee included six professional schools in its study: medicine, public health, dentistry, business administration, education, and law. I have drawn on the Harvard survey particularly in preparing this review. The Michigan survey also included a particularly useful discussion on the utilization of the behavioral sciences in the professional fields.

One cannot read these documents without becoming aware of the striking similarity of the problems which physician and industrialist and lawyer and social worker encounter in seeking to make use of social science theory and research. This similarity stimulated the present attempt to identify common elements in the relationships of professional fields and the behavioral sciences and to suggest some of the conditions for effective collaborative work.

A parenthetical note is in order before proceeding to this review. For purposes of this paper the distinction between the behavioral sciences and social sciences is not important. Behavioral science is the term which the Ford Foundation has adopted to cut across the con-

during one of the discussions of a faculty seminar on the research basis of social welfare practice. This seminar participated in the behavioral science survey at that university. The sociologist had reviewed the findings that had been developed in social psychology about the effect of class status on the way a child responds to frustration. He then wanted to know why material of this kind could not be organized systematically and taught to social work students in place of the time-consuming and unsystematic method of case teaching. The case-work teacher finally traced her reluctance about following such a procedure to her concern lest students see class status as the only or primary factor in the child's reaction to frustration instead of as one of several forces operating in the child's experience.

The case method of teaching assures that generalizations and theories such as those about the influence of class status will always be seen in the context of the total life experience of the individual. Professionals always have to take into account the total situation which falls within the province of their particular service, not just a conveniently circumscribed aspect of it. This is probably one of the important reasons for the retention of the case method in law, in business, and in social work even as knowledge has become better organized and systematized.

The other characteristic method of the professions, as contrasted with the social sciences, in carrying on their research and educational work, is an intimate and continuing interaction with the applied field. The Harvard Law School's Committee on Legal Education said on this point, "[This professional nexus] is the only practicable insurance against getting lost in intellectual blind alleys. The scholar who isolates himself from the practice of his profession easily confuses what is intellectually challenging with what is really significant in human affairs" (2*g*). Now to the social scientist, exposure to and involvement in the complex and practical concerns of a profession is a hazard and may subvert his ability to make his peculiar contribution. Isolation from the concerns of a profession, on the other hand, is a hazard to the professional and may render his contribution peripheral or irrelevant.

There are many more characteristics of the social sciences and the professions which are pointed up in the behavioral science surveys. I have not attempted a systematic cataloging of them but have selected those which I think are particularly relevant to the situation of medical social work and the social sciences. The question now comes, what are the implications of this review for research and teaching in medical social work?

Suggestions for Collaborative Work

Several general suggestions for collaborative effort can be found in the survey volumes. Before reviewing these, it is worth noting the expressions of conviction about the worthwhileness of collaborative work. A visiting committee of scholars from other universities, which was assigned the task of reviewing and commenting on the report at Harvard, wrote: "The net impression is imparted that collaboration is fraught with very great difficulties. Its advantages are so great, however, that we wish to express our belief that the gains are worth the costs" (2*h*).

From the University of Michigan Survey Committee comes this appraisal of the need for more active collaboration between professional schools and social science departments: "The professional school staff member is likely to be intimately acquainted with the history and the current institutional factors in the field situation. This rapport with administrators and practitioners in the field gives him valuable insights into relevant problems and variables. Those behavioral scientists whose work requires a field setting will undoubtedly find it desirable if not necessary to work in collaboration with professional school faculty who may approach the same substantive situations with somewhat different interest" (3).

A wholesome warning not to exhaust one's energies in looking for the best pattern for relating professional practitioners and social scientists is given in the Harvard report. The Harvard committee observes that the organizational formula which might insure fruitful research remains, like the philosopher's stone, undiscovered. Formulas put forward eagerly by one or another exponent of science in praes-

could be noted, but the point here is that climate does differ, and special attention to problems of acclimatization is required if the social scientist or practitioner is to survive and be useful in an alien setting.

Differences in Goals

Now, as to differences in goals, the typical goal of the social scientist is development of adequate laws or generalizations or theories to account for the portion of the world that he studies. The typical goal of the practitioner is knowledge as a guide to actions for which he is responsible. This statement implies a black-and-white contrast between science and practice, but it should be understood that there are various shadings of gray in the actual way in which a particular social science or profession may present itself. Some of the social sciences are much "purer" than others in the sense of seeking knowledge for the sake of knowledge. There is considerable variation between campuses in this regard. The committee at Harvard concluded that, on the Harvard campus at least, "the balance seems definitely to favor the pursuit of knowledge for its own sake" (2*d*).

Just as theory rather than application takes priority in the social science disciplines, so does research methodology become a goal which is seen as worth while in itself. This acceptance of tool development as a worthwhile goal in itself is seen perhaps most clearly in the strong support expressed in several of the surveys for strengthening the field of mathematical statistics. The attitude reflects a division of labor in social science which is so taken for granted it is not always explained or justified.

However, there are some dissenting voices in the social sciences themselves with respect to methodological preoccupations. One Harvard social scientist commented that social scientists are more preoccupied with ways of thinking about problems than in actually working on them (2*e*). And another one quoted approvingly a comment of Freud's to the effect that there comes a time when you ought to stop cleaning your spectacles and take a look through them (2*f*). All of this simply underscores the fact that between the black-and-white contrasts

being pointed up here, there are important shades of gray.

Perhaps one other difference in the goal of the social sciences and the professions is worth noting. In the professions, the object of research is not simply the condition being treated, whether it be a disease or a falling profit rate or the breakup of a family. The practitioner is interested in the facility for treating the condition. In the medical social work field, this means the physician and hospital, the medical social worker, and the various resources that can be called into play in working with the patient. Action must always be guided by understanding of both the condition and the treatment. To the scientist, however, the treatment may appear too variable to lead to knowledge of general significance, and it will not be the focus of his research as frequently as the condition being treated.

So much, then, for differences and similarities in goals. The differences appear, we must recall, at the point where two activities which are seeking to maintain their institutional identities come together. Seen from a broader view, the goals of the professions and the social sciences are unified within the broad societal goals which form the ground within which a division of labor has taken place.

The Methods of Science and Practice

There are just two contrasts between the methods or procedures of the social sciences and professions which I want to report to you from the surveys made of the social science departments and professional schools. One is the widespread use of the case method in all the professional schools, but particularly law and business administration. The stress on the case method reflects, I think, the basic caution of the practitioner about the danger of the "trained incapacity" of the social scientist, to borrow one of Thorstein Veblen's terms. That is, the social scientist, by focusing on that portion of reality which is abstracted and brought into focus by theory, may obscure the larger context of the object of study.

An interesting instance of this came up in a discussion between a sociologist and social case-work teacher at the University of Michigan

ous process of osmosis. Provision must be made for collaborative work on the part of social scientists and professionals in concept formulation and research and writing. The committee in the Harvard business school wrote on this point: "The School has recognized that research is essentially a full time activity. The School has set forth as a goal, therefore, that each member of the faculty can have the equivalent of one year in three free from instruction responsibility to engage in research" (27). This is an ambitious goal. It is based, however, on a realistic appraisal of the investment required in time and energy from the field of practice if collaborative work between practitioner and social scientist is to bear fruit.

Another way to achieve a setting for productive collaborative work between social scientists and members of professional schools is the device of dual appointments. A social scientist is given faculty status both in his own discipline, thereby protecting his own career line, and in the professional school, thereby giving him an identification with the profession and its goals. This arrangement is already in effect in several universities and no doubt has value.

If we turn to the health field, both medicine and public health, we find in the Harvard report numerous statements indicating uncertainty as to the best procedures for fostering collaborative effort. The committee states: "We are unwilling at this juncture to make specific permanent recommendations with regard to integration of behavioral scientists in the health area. There are a number of fundamental issues which involve both the behavioral sciences and the health schools on which policy decisions must be made on both sides before any sort of organizational change could be reasonably advocated" (28).

Of the several factors one can look for in the Harvard report in explanation of this uncertainty, the underlying one seems to be the self-sufficiency of medicine and the extremely effective indoctrination which medical education is able to achieve with respect to the goals and the methods and the theory of medical care. The committee encountered extensive ignorance about the social sciences in the medical school faculty, and many doctors saw no difference be-

tween the role of social scientists and trained social workers. There were some who had strong feelings that the social scientist was not really scientific, failed to understand the problems of the physician, and did not accept the type of responsibility which seems natural to the physician.

The social scientists, on the other hand, saw the doctor committed to short-term goals which made difficult the conduct of research that did not have an immediate pay-off. Also they found that the doctors tended to insist on administrative "control" of projects, thus threatening the integrity of the research as seen by the social scientist.

Out of this analysis of the problems of research in the health setting, the Harvard committee came up with a proposal that parallels almost exactly the proposal which the Michigan faculty seminar on the research basis of social welfare practice, referred to earlier, developed with respect to the field of social work. Let me quote:

"The experience of the committee in preparing this report has made patent the need for a forum in which the study of human behavior in relation to medicine can be continued. . . . It is recommended that a standing committee drawn from the faculties of the Schools of Public Health and Medicine with appropriate representation from the Faculty of Arts and Sciences be established. The nucleus of the committee would consist of an executive secretary and sufficient clerical help to enable it to function continually. As conceived, the committee would in no sense make policy or act as an authoritarian body but would exist primarily as an interfaculty study unit and consulting service . . ." (29).

Essentially, the approach arrived at by the Harvard committee and the Michigan faculty seminar is to avoid elaborate administrative machinery and to provide, instead, staff service and research funds to stimulate cooperative work between interested behavioral scientists and interested members of the professional school faculty. No centralized direction of research effort is contemplated, but instead a building on existing interest and strength. The approach rests on the faith that the best way

tice are suspect in any case. The fact is that collaboration remains more of an art than a science and must be played by ear if errors are to be corrected as they appear.

Nevertheless, considerable wisdom about collaboration between the sciences and fields of practice is embodied in the surveys.

The first point I wish to report is the consensus in these behavioral science surveys that the adaptations of science to the professions must take place in the professional schools. For social work, this means the application of the various behavioral sciences to social work problems will not come about if dependence is placed on departments of psychology, economics, or sociology to do this work. It must be done within and by the professional schools themselves.

The School of Education at Harvard provides an example of a bold approach to this problem. Some years ago the Harvard School of Education established the laboratory of human development and brought in a psychologist to head it. Its present head is an anthropologist. The laboratory was designed as a social science research center, not as a research service available for teachers and school administrators. The problems selected for research are those seen by the scientists as important and amenable to research with the theory and methodology available in the sciences.

Noting the heavy emphasis which has resulted on basic rather than applied problems, the Harvard committee states: "Some might feel that the School was neglecting its responsibilities to the educational profession by taking this position. It is felt, however, that more applied problems will eventually be more adequately solved if they are attacked with the methods and assumptions which have been developed by basic research, than if they are approached on an ad hoc basis. It is possible that this policy of the school will result in the neglect of more applied problems and too much emphasis on basic research, but the behavioral scientists on the staff do not think it will". (2i).

Every profession would be strengthened if a few of its professional schools set themselves the long-range task which the laboratory of

human development at Harvard has set for itself. It is worth noting that this research center is organized around one component in the educational process: the child. Other components such as the organization of the school system, the selection and training of teachers, and so forth, will need to be met with other research resources.

The surveys contain examples of other models for incorporating behavioral scientists into the professional schools. The School of Business Administration at Harvard provides us with a case in point.

A committee in the School of Business Administration expressed concern lest a scientific approach result in singling out one part of a problem, and underscored heavily the importance of seeing and weighing all the facets of a problem in the practice of business administration. The committee writes: "It is this recognition of the multidimensional character of the problems of business administration which has led to the belief at the School that the adaptation of the basic disciplines of the behavioral sciences to the problems of business administration must be made here at the School, rather than by various groups of behavioral scientists themselves. Each problem must utilize knowledge, insights, and techniques of analysis derived from more than one of the behavioral and social sciences" (2j).

How to tap the contributions of the social sciences for business administration? A number of procedures are suggested, but perhaps the crucial one is this: "There is need to add to the permanent faculty a few men thoroughly trained in the range of behavioral sciences embraced by the Social Relations Department who would serve as focal points in the faculty to assist in the adaptation of these fields to the problems of business administration" (2k). Note that it is assumed the men brought in will remain social scientists and not become experts in business administration. But their attention will be focused on the problems of business, and their research will draw heavily on the business setting for its data.

Of course, the presence of social scientists in a professional school will not affect theory and practice in the field through some mysteri-

Trends in Brucellosis Control

By K. F. MEYER, M.D.

BRUCELLOSIS is a world health problem ranking near the top of the ever-lengthening list of infections transmitted from animals to man in its effect on human and animal health and in its economic importance (1-4). Unfortunately the extent of its prevalence in large areas of the world is virtually unknown. The number of reported cases in human beings undoubtedly does not represent the number of cases that occur. This infection directly affects large segments of the agricultural population and other exposed groups through prolonged illness and reduced capacity for work. These burdens fall particularly heavily on Latin American and Mediterranean areas where the prevalence of *Brucella melitensis* in goats is high.

Epidemiology

Most of the infections result from direct contact with post birth discharges, fetal membranes, and fetuses from infected animals when they give birth or abort, or from contact during slaughter. A significant number of patients

also acquire it through ingestion of dairy products from infected cattle and goats.

The three species of *Brucella* known to infect man—*abortus*, *melitensis* and *suis*—resemble each other so closely that they can be distinguished only by special tests. Probably these three species descended from a common bacterial ancestor and acquired special characteristics on adaptation to a new host. The fairly balanced relationship between *B. abortus* and cattle suggests that this species may have been the first. In general, swine and goats react more strongly to infection by *B. suis* and *B. melitensis*, respectively, than cattle do to *B. abortus*. There may be further support for the idea that *B. abortus* is the oldest species in the conjectured absence, or at least infrequency, of natural *Brucella* infection among wild animals. It does, however, occur in the American bison, the water buffalo, and the European hare. The docile ox was among the first animals to be domesticated by man; swine, sheep, and goats entered his environment later. The reactions of all animals, including man, that acquire *B. melitensis* or *B. suis* infections speak of the more recent appearance of these two species.

In areas where numerous herds of cattle are infected by *B. abortus*, persons who drink unpasteurized milk are exposed to it. Although the tissues of these persons are invaded, clinical signs and symptoms arise in remarkably fewer persons than the number actually infected. In a rural population exposed to bovine brucellosis through consumption of raw milk, the intradermal skin test using brucellergen may yield a high percentage of positive results but very few clinical cases of brucellosis.

Dr. Meyer is director emeritus, George Williams Hooper Foundation for Medical Research, and professor emeritus of experimental pathology at the University of California. This paper is based on an address given at the United States-Mexico Border Public Health Association meeting in May 1955. The original paper appeared in the April 1956 issue of the *Boletín de la Oficina Sanitaria Panamericana* in the Spanish language. Briefs of six other papers given at the meeting appeared in *Public Health Reports*, December 1955, pp. 1213-1221.

to define problems and plan research is to do research. Regardless at what point one starts, an encounter with the data brings to the fore the salient problems and directs research effort along these lines.

Conclusion

The kind of surveys sponsored by the Ford Foundation and carried out by the five universities are valuable and have their place. They are an excellent first step in establishing communication and in identifying common interests and goals. Not until research is under way, however, not until particular social scientists and particular members of practicing professions sit down together to design research and collect and analyze data, will we be able to answer the kinds of questions which caused the Harvard committee to refuse to make specific recommendations as to how to integrate the social sciences and the health professions.

Medical social work is in a strategic position in many respects to work out and demonstrate effective ways of bringing the specialized approaches of the behavioral sciences to the problems of practice in both the health and welfare fields. Medical social workers know their way around the health field; they are aware of the subculture of the hospital and clinic;

and they share the same sense of responsibility as does the medical doctor with respect to the patient. At the same time, the primary focus of the medical social worker is the same as that of the social scientist: individuals and institutions and their interaction.

Application Deadlines Waived

Deadlines for filing applications for research grants for studies of limited scope and size have been waived by the National Institutes of Health of the Public Health Service in order to provide rapid and flexible support for meritorious, limited studies. As of March 21, 1956, the usual deadlines of March 1, July 1, and November 1 have been waived, on an experimental basis, for about one year.

Types of applications still subject to "regular deadlines" are those that request more than \$2,000 plus indirect costs or request more than

one year of support or supplements to existing grants or applications.

Other policies and rules governing applications remain in force. If more extensive support should be required to continue the studies initiated, the investigator should apply for a grant according to the usual deadlines. Grants are not intended to support research typically designed for writing a thesis.

All applications as well as requests for forms or information should be addressed to the Division of Research Grants, National Institutes of Health, Bethesda 14, Md.

been estimated at between \$3 million and \$25 million. Unfortunately, similar estimates are not available for other countries.

Bovine brucellosis, wherever it occurs, is the cause of very considerable economic loss to the dairyman, with effects probably greater than he generally has realized. Norway has estimated the cost of eradication at less than one year's economic loss due to the disease.

Equally incomplete are the estimates on the losses sustained as the result of brucellosis in goat and sheep raising areas. In southern France, 15 to 40 percent of the flocks or herds are infected; 10 to 40 percent of the infected goats or sheep abort; and thus, annually 100,000 ewes and 50,000 goat kids are lost (7). No one has yet appraised the impact of these losses, in combination with the ravages of disease, on health and well-being in many countries. This negligence is in great part attributable to the lack of recognition by many that this disease is a specific entity because it is so insidious and difficult to diagnose.

Control

In improving the welfare of countries throughout the world, brucellosis must obviously be considered. The World Health Organization and the Food and Agricultural Organization, advised by an expert panel comprised of medical and veterinary experts from all parts of the world, closely collaborating with the International Office of Epizootics and several inter-American congresses, are attacking the problems on a worldwide basis. Human brucellosis can be prevented only if the disease is eliminated from animals. The present goal—complete eradication of bovine brucellosis, rather than adaptation to it—guides the measures taken by these groups.

This is a difficult task, but progress made in the United States, Puerto Rico, and Scandinavian countries (8) gives cause for hope. That infection in cows can be recognized with considerable accuracy by a simple test for agglutinins in their serum was proved nearly 50 years ago. To eradicate bovine brucellosis, early efforts were directed toward destruction of reactors in this test, just as they were in the

campaign against tuberculosis. Regrettably, the test-and-slaughter type of control, when conscientiously followed, is so costly in some parts of the world that it has not been practical to adopt it on a worldwide basis.

Cooperation of the livestock owner cannot depend on legislation alone. An effective educational program, fortified with accurate information, must leave no doubt in the minds of all concerned that living without brucellosis is a desirable necessity.

Efforts to devise an effective, workable, and acceptable control program brought to light several shortcomings in the original planning. Possibly one of the most troublesome is the nature of the agglutination test itself. It has the advantage of being comparatively inexpensive and may be repeated as often as necessary, but it has some disadvantages. For one, the results may be misleading. The serum from some uninfected cows may cause nonspecific agglutination, or early in the infection agglutinins may not be detectable. It has happened that herds considered to be free from the infection on the basis of the test and subsequent slaughter of the reactors later became infected. This disappointing and sometimes disastrous failure occurred usually when the slaughtered animals had been replaced with stock from herds not included in the testing program. Another shortcoming was lack of proper and comprehensive education of all groups concerned and consequently difficulties in the organization of cooperative efforts between livestock owners and livestock sanitary officials.

At a disappointing stage of the control program, progress took a significant and encouraging turn. Through research by Buck (9), Buck and Cotton (10), and Traum (11), a *B. abortus* strain, strain 19, proved effective in preventing abortion in heifers vaccinated when they were 4 to 8 months old. In experimental studies, heifers vaccinated as calves have maintained, during their first gestation, a serviceable protection against brucellosis when exposed by contact with infected cattle. Strain 19, living but attenuated, provides protection, usually without causing disease, because it is of stabilized virulence and produces a low-grade, temporary infection from which the vaccinated ani-

In addition to the relatively low virulence of *B. abortus*, other factors tend to lessen the danger of drinking milk contaminated with that organism. Infected milk may be diluted with large amounts of uninfected milk at the dairy; but more important, children, the consumers of the largest quantities of milk, are naturally resistant to clinical illness after exposure to *Brucella*. These conditions account for the fact that most human brucellosis due to *B. abortus* results from direct contact with farm animals or their carcasses, but they do not minimize the necessity for pasteurization.

The organisms usually enter through intact skin or mucous membrane. Most of the people who contract clinical cases of brucellosis due to *B. abortus* have handled infected cattle, occasionally infected hogs. Hogs in close association with infected cattle in feed lots may acquire *B. abortus*. Recently sheep in California have also been found to be infected with *B. abortus*.

In some States, such as Iowa, where swine breeding is carried on extensively, swine brucellosis constitutes a threat to human welfare. It may be transmitted to man in two ways: by direct contact with infected hogs or by indirect spread to dairy cattle sharing premises with infected hogs. Under the latter circumstance, the potentialities are worth considering because *B. suis*, in general more pathogenic for man than *B. abortus*, may, in rare instances, reach consumers of raw milk. Usually, however, it is sporadic, appearing in persons who suffer individual exposure by direct contact with single infected animals on the farm or in the slaughterhouse.

Brucellosis in goats is widespread and is the chief source of human brucellosis in Mexico, France, Italy, Spain, Yugoslavia, Turkey, Israel, and Egypt. About 30 years ago the goat was the source of a limited number of cases in southwestern United States. The mortality rate ranges from 4 to 11 percent. *B. melitensis* may infect cattle too, and the situation mentioned with regard to *B. suis* may arise—consumers of raw milk may become infected. In the United States, human infection with *B. melitensis* has recently been traced to hogs. In other countries, for example, in France and recently Germany (5), sheep have

been proved important sources of severe, even fatal, human infections.

The portal of entry of *B. melitensis* is by ingestion, contact, or inhalation of infected dust in the environment of the livestock. Both goats and sheep are the source of dairy products, particularly fresh cheese, and these may be teeming with *Brucella*. If the cheese is sticky, it is likely to remain in the mouth for an appreciable time, thus giving opportunity for the organisms to enter by way of the mucous membrane of the mouth and to bypass the potentially destructive gastric juices. Usually, in human brucellosis of caprine origin, several members of a family are infected simultaneously; in brucellosis of bovine origin, only single cases occur in households.

The soil in goat corrals and stables may be heavily contaminated with *Brucella* that continuously pass in the feces. Being resistant to desiccation, the viable organisms are readily disbursed in the dust stirred up by moving animals. Ingestion of stagnant water from watering places in goat corrals is also a potential source of infection for the goats.

Economic Aspects

Brucellosis, in contrast to many other zoonoses, is responsible not only for widespread illness and misery among human beings, but also for serious economic losses to those who deal in livestock. These losses are of such appalling size in some areas that they are the subject of more concern to many groups than the burdens of disease carried by the people who contract it. In general, the losses consist of (a) decrease in milk supply—an average of 22 percent; (b) loss in offspring because of destruction of fertility—an average of 40 percent—or abortion; and (c) decrease in value of infected cows, goats, sheep, swine, and horses.

According to figures of the National Research Council (6), at least 1,300,000 dairy cows and 800,000 beef cattle in the United States had brucellosis, and the resultant financial loss was estimated at \$100 million. According to a more recent estimate by the Agriculture Research Service, the annual loss has been reduced to \$45 million. The damage caused by *B. abortus* to agriculture in Switzerland during 1 year has

Manthei (14) used culture of milk to determine the infection status of vaccinated and unvaccinated herds, and by this means were able to evaluate the shedder status, seroagglutination test, and the relationship of these to vaccination with strain 19.

There is no need to emphasize again that the final determination of the infection status, of either an individual or herd, cannot be made safely on the basis of the ring test or culture of milk alone. These procedures have certain inherent limitations, especially when applied to vaccinated herds, but they are exceedingly valuable when used as supplements to the blood test. When proper use is made of all these procedures, each in its proper place, together with prompt identification and removal or segregation of diseased animals and with application of sound sanitary practice, satisfactory progress towards eradication can be expected to continue.

When undue weight is given to a negative ring test, when blood test reactions shown by vaccinated animals are ignored or unduly discounted, or when seroreactors, untested animals, or seronegative animals from herds of unknown origin are permitted to move in the channel of trade other than to immediate slaughter, progress towards eradication is impeded. It is, of course, wasteful to introduce infection-free animals into infected herds, as experience in Latin America has regrettably shown.

Certainly the interstate regulations pertaining to brucellosis within the United States, as recommended in 1953 (16), might very well be applied to the regulation of importation of cattle into the Latin American countries.

Caprine Brucellosis

Observations made by Dr. G. Renoux, acting director at the Pasteur Institute in Tunis, described by him during a visit in May 1954, may serve to introduce a discussion of control of caprine brucellosis.

A program is being carried out there with the help of grants from FAO and WHO. Susceptible goats, imported into Tunis from Sweden, were artificially infected by the conjunctival route, and the LD₅₀ infective dose for this animal was determined. The mean LD₅₀ infective dose of the most pathogenic strain, *B.*

melitensis 53H38 of Mexican origin, was 20,000 organisms (range: 8,300–48,000). Probably the goats that received small infective doses recovered spontaneously. Mutton breeds of sheep were resistant; the LD₅₀ was 400,000 *B. melitensis* of the same strain. This does not necessarily apply to milking sheep. Age, sex, or pregnancy had no influence on the susceptibility of goats. Kids were susceptible to infection, and some remained infected for many weeks. Subclinically infected goats that acquired the infection as kids doubtlessly play a part in the epidemiology of caprine brucellosis.

With the aid of the inhibiting medium developed by Kuzdas and Morse (17), *B. melitensis* was readily isolated from the feces of heavily infected goats, and from the vagina, quite independent of pregnancy and parturition. Milk of nonparturient goats contained *B. melitensis* as often as did the milk from dams. The centrifuge deposits from the milk, more often than cream, contained *B. melitensis*; evidence of *B. abortus* is more often found in the cream.

The rapid plate or test tube agglutination test remained consistently negative in a number of infected goats excreting *Brucella*. The agglutination titer varied widely from test to test in the same goat. The prozone phenomenon occurred frequently in goat serum. Blocking antibodies appeared to be specific. They were found in more than 90 percent of negative sera from infected goats. The injection of melitine, a skin test antigen prepared from *B. melitensis*, had no apparent influence on the agglutination titer.

The allergic state appeared slowly after infection, and the intradermal tests were strongly positive in heavily infected goats.

Until the tests in Tunis are more complete, recommendations for control rest on former experiences.

Caprine or ovine brucellosis is of tremendous social importance in rural life; this was strikingly illustrated when it was recently introduced into Yugoslavia. It has been effectively eradicated by slaughter of entire herds as soon as the infection is discovered. This public health action is justified because the disease in these animals assumes a chronic form which goes undetected unless special tests are made

imals recover completely. There is absolutely no transmission from vaccinated to susceptible animals. Abortion has occurred infrequently, and only when the heifer was vaccinated during pregnancy.

The vaccine prepared with strain 19 suspended in saline proved to be a highly perishable product, subject to deterioration by handling under adverse conditions. Many so-called vaccine failures, doubtless due to vaccination with dead or inactive organisms, led to another series of disappointments. Now a process of lyophilization or dehydration of the organisms from the frozen state under vacuum (12) seems to offer more promise. The vaccine so produced, which often unfortunately loses 50 percent of the original viable cells in its preparation, is now the one of choice.

To insure proper supervision of production of the standard vaccine, the California Legislature has empowered the State health department to test biological products and enforce proper transport and storage methods. In California, which has adopted a compulsory vaccination program, and in other States with semicompulsory programs, the overall protection has been remarkably good in most cases. Losses from abortion have been sharply reduced.

The degree of immunity provoked by single or multiple vaccinations has been studied, and in no instance has revaccination enhanced immunity. It is fully recognized that ultimate eradication will be achieved only by using the vaccination of calves as a supplement to blood testing and elimination of the reactors.

Until a thoroughly satisfactory practical field test is devised to distinguish between vaccinal agglutination reactions and reactions due to virulent infection, an animal whose serum reacts at certain levels in this test, whether vaccinated or not, particularly after it attains breeding age, must be considered a dangerous animal. The titer now regarded as positive is 1:200 for vaccinated animals. From the standpoint of the public's health, it is absolutely imperative that these animals, particularly if they are shedding *B. abortus* in milk, be eliminated.

Recent observations on 30 herds, consisting of 2,958 animals in which calfhoo vaccination

had been practiced for 5 years, revealed 89 shedders. Only 4 herds were entirely free from infection. Since the percentage of reactors, and in particular of shedders, is low, it is reasonable to postulate that the next step is to identify the shedders by means of a simple method. From the standpoint of the beef herd, it is relevant only to remove the shedders from its midst; from the standpoint of spread of the infection, it is essential to take whatever preventive measures are possible, preferably slaughter.

The application of new methods of culturing milk and cream on special media has the advantage that it furnishes health agencies with valuable information about the progress of an eradication program in milk herds. The methods outlined by Hess and Sackmann (13) or by Goode and his associates (14) should be tried.

The agglutination test was modified to detect *Brucella* agglutinins in milk by Fleischhauer (15); the modified test is called the milk or cream ring test, Abortus-Bang-Ring (ABR), or lacto-agglutination test. Its success depends on a suitable antigen prepared from a heavy suspension of *Brucella* stained with hematoxylin. It is carried out by adding antigen to milk in the proportion of 1 drop per 1 ml. After incubation at 37° C. for 1 hour, the sample is centrifuged and read. Agglutinated stained organisms adhere to the fat globules and rise to the surface; the fat containing the stained organisms causes the layer of milk or cream to be purple.

This test has been used extensively in the United States and in Denmark. Three consecutive negative ring tests on a composite herd sample, 4 to 6 months apart, followed by one negative agglutination test on blood from all animals in the herd, are the criteria for freedom from infection. In Grade A herds the three negative ring tests alone are considered adequate criteria. In the United States a number of States have surveyed milk sheds in cooperation with livestock disease control agencies. This test was proved valuable as a field test, particularly in detecting *Brucella*-positive herds (14).

In an extensive, long-range, thorough study of udder infections, Goode, Amerault, and

Manthei (14) used culture of milk to determine the infection status of vaccinated and unvaccinated herds, and by this means were able to evaluate the shedder status, seroagglutination test, and the relationship of these to vaccination with strain 19.

The application of new methods of culturing milk and cream on special media has the advantage that it furnishes health agencies with valuable information about the progress of an eradication program in milk herds. The methods outlined by Hess and Sackmann (13) or by Goode and his associates (14) should be tried.

The agglutination test was modified to detect *Brucella* agglutinins in milk by Fleischhauer (15); the modified test is called the milk or cream ring test, Abortus-Bang-Ring (ABR), or lacto-agglutination test. Its success depends on a suitable antigen prepared from a heavy suspension of *Brucella* stained with hematoxylin. It is carried out by adding antigen to milk in the proportion of 1 drop per 1 ml. After incubation at 37° C. for 1 hour, the sample is centrifuged and read. Agglutinated stained organisms adhere to the fat globules and rise to the surface; the fat containing the stained organisms causes the layer of milk or cream to be purple.

This test has been used extensively in the United States and in Denmark. Three consecutive negative ring tests on a composite herd sample, 4 to 6 months apart, followed by one negative agglutination test on blood from all animals in the herd, are the criteria for freedom from infection. In Grade A herds the three negative ring tests alone are considered adequate criteria. In the United States a number of States have surveyed milk sheds in cooperation with livestock disease control agencies. This test was proved valuable as a field test, particularly in detecting *Brucella*-positive herds (14).

In an extensive, long-range, thorough study of udder infections, Goode, Amerault, and

fied by the normal host could be isolated, and this has been done with *B. abortus* and *B. suis* by Berman at Wisconsin University. By supplying a preformed nutritional factor to the host one could propagate the organism at will until an effective immunity is induced. At this point, withdrawal of the required growth substrate would stop growth of the organism, and the host's normal and actively acquired immunity would clear the host's tissue of the organism.

To this end, Elberg and his associates developed a largely streptomycin-dependent mutant of *B. melitensis*. This mutant protected 50 percent of animals vaccinated with it against fairly heavy challenge—the ID_{50} (infectious dose) for mice, 10 to 20 percent; for guinea pigs, 5 to 10; for goats, 1; and for monkeys, 5. Challenge consisted of two injections of 10^{10} cells administered subcutaneously.

Unfortunately, streptomycin could not reach the intracellularly located organisms and therefore could not stimulate their growth. They were able to multiply threefold to fourfold, using the streptomycin they had accumulated in their cytoplasm during growth on the agar containing streptomycin. The strain was not pathogenic according to gross and microscopic histopathologic criteria.

A more proliferative immunizing agent was then isolated from the drug-dependent population on drug-free medium. This mutant was studied carefully and found not to be drug dependent. It was not pathogenic for goats nor for some other animals, but it was less attenuated than the streptomycin-dependent strains in that it multiplied more profusely in mice and guinea pigs. As a result of this ability to multiply, revertant strain 1, among others, was able, in a dose of 10^3 cells, to immunize 70 percent of mice against 220 ID_{50} and 60 percent of guinea pigs against 35 to 50 ID_{50} . Goats and monkeys have not yet been tested.

The *in vivo* proliferation of revertant strain 1 is such that it multiplies and persists in the spleen of the vaccinated for 11 weeks before it is cleared from the organs. Challenge is conducted at least 6 weeks after the strain is cleared. It is believed that the actual imprint of the immunity depots is more intense quantitatively, and hypothetically it may be taking place with

antigens only slightly, if at all, produced *in vitro*.

These observations can be interpreted as follows: A living attenuated *B. melitensis* that persists in the tissues after inoculation for only a limited time and produces a "native" *Brucella* antigen does protect highly susceptible small laboratory animals against a moderately severe infection. Apparently a *B. melitensis* variant may be obtained through adaptation of the organisms *in vitro*. The protective value of such a variant in active immunization of goats has yet to be determined.

Why has this apparently complicated road of experimentation been chosen? The chance of selecting from a *B. melitensis* population growing on a culture plate, a variant of low pathogenicity and high immunogenicity, is so low and the work entailed so time consuming that forcing the development of an immunogenic strain by gradual adaptation to streptomycin seems more promising. Actual experimentation justified the taking of this road, and the progress being made brings the development of an effective method of immunization against caprine brucellosis much nearer.

Rather unfortunately, only two laboratories—the Brucellosis Center at the Pasteur Institute at Tunis, supported by FAO and in cooperation with WHO, and the department of bacteriology at the University of California, assisted by a small grant from the Public Health Service National Institutes of Health—are devoting their energies to the solution of this problem of such importance to the welfare of populations who can ill afford the constant direct and indirect injuries inflicted by caprine brucellosis.

General Recommendations

1. A control program against brucellosis should be undertaken with full, friendly cooperation of the United States Department of Agriculture, Agriculture Research Service, State and local health departments, and livestock owners.

2. A systematic survey of the extent and distribution of brucellosis in different animals where this is not known should precede formulation of a control program.

3. Well-equipped and adequately staffed central and field laboratories are essential.

and then continues to persist in the newly infected country.

In Latin America, the disease has existed for centuries and is chronic. The problems to be met are these:

1. The diagnostic tests needed to guide the recognition and elimination of infected excretors of *B. melitensis* frequently cannot be made on the scale required, and, if it can, only with great difficulties. The usual agglutination test has limitations. It must be interpreted on a herd basis, not on an individual animal basis. In a personal communication, Renoux wrote that the ring test modified for study of goat's milk appears to be highly specific if the test tubes are incubated for 12 hours at 37° C. Work on this test is also being carried out by Alivisatos and Edipides (18). The test may offer a solution to some of the present diagnostic problems. Twenty years ago, it was pointed out that the intradermal allergy test detects the infected individual goat probably more accurately than the most refined serologic tests (19). Suitable antigens are now available, but the effort required to apply the test is apparently a deterrent factor to its use.

2. Removal of goats with positive reactions to the various tests must be accompanied by strict sanitary herd management, particularly in areas where goats and man live in close association. Those familiar with goat-breeding practices carried out by poor settlers and farmers who own small herds that feed on natural ranges of sandy semidesert and rough and broken terrain fully appreciate the difficulties of accomplishing much in this respect. An educational program—carefully adapted to local needs and skillfully executed until its goals are achieved—is required to familiarize the people with the economic and social consequences of the loss of kids and lambs and the spread of the infection to man. Furthermore, it is never appreciated, and therefore rarely adequately emphasized, that the environment of human habitations where goats infected with *B. melitensis* have been housed for decades is thoroughly impregnated with the infective agent. How to remove the *Brucella* from this contaminated environment is not known, and little effort has been spent in studying the condi-

tions required to accomplish the desired results.

3. Even if all of these requirements could be met and a dependable test-and-slaughter program could be contemplated, the thoughtful health official would still need to look ahead. A primitive people dependent solely on the goat for milk and milk products must receive financial aid from their government because they can meet brucellosis only by replacing stock through importation of clean animals. This is not compatible with the economy of the countries most heavily burdened by caprine brucellosis. Temporary losses will be more than compensated for in the future. Fewer animals will be lost by abortion and productivity will be increased.

The usefulness of calfhood vaccination with strain 19 has already been touched on. This suggests the necessity of further work to find a strain of *B. melitensis* suitable for vaccination of goats and sheep. It seems apparent that no effort should be spared to discover such a vaccine. Meanwhile, one might reflect on some of the problems that lie ahead in this effort. A limited series of tests have shown that goats that have recovered from *B. melitensis* infection have an immunity that rapidly and effectively frees their tissues from the infective agent when they are given relatively large doses of virulent *B. melitensis*. They are not immune to infection with *B. abortus*. Thus, acquired immunity in goats is a proved biological state.

Little present evidence encourages the hope that a killed vaccine or strain 19 can confer an adequate immunity against the continuous chances of infection prevailing in goat-raising areas. On the other hand, an overwhelming amount of data from France, England, Australia, and the United States leave little doubt that at the moment the only effective immunity against *Brucella* abortion is induced by in vivo proliferation of the vaccinating or infecting agent. It must be concluded for the time being that the in vivo synthesis of immunizing antigens is of superior immunogenicity—either in quality or quantity—to that produced by organisms grown on artificial medium. Finding a *B. melitensis* strain with these properties is a difficult task.

Elberg, in a personal communication, offered the hypothesis that a population of *B. melitensis* which has nutritional requirements not satis-

Service Statistics in Public Health

THE RENAISSANCE of interest among public health administrators in the planning and evaluation of public health programs highlights the importance of the work currently being done by the Public Health Conference on Records and Statistics.

Within the past three decades, a number of approaches have been made to the description of health department performance and the impact of public health programs. Outstanding results of these efforts are the several editions of appraisal forms for local health work issued by the Committee on Administrative Practice of the American Public Health Association, the tabulation of health department services prepared by the Committee on Records and Reports of the Conference of State and Territorial Health Officers, and, more recently, the Evaluation Schedule and Health Practice Indices developed by the Committee on Administrative Practice of the American Public Health Association. Successively, these several reporting instruments have been valuable tools for the use of local health departments in reviewing their operations. They have stimulated critical self-appraisal, an essential to growth and improvement of service.

As stock-taking techniques have been more widely applied, deficiencies in available operational statistics have become increasingly apparent. The volume of statistical information accumulated has steadily increased; yet much of it has been collected without specific purpose and, therefore, has been of minimum worth. Frequently, it is limited to enumeration of units of service, with no link to any sort of population base from which to measure program progress. For example, immunizations of various types, given at specified places, within designated periods of time, are customarily

counted, but they are not related to the number of children of different age groups who should be immunized. Also, it is usual to maintain figures on attendance at the several kinds of health department clinics but unusual to relate such attendance to the number of persons who needed the service provided. Statistics kept in far too many health departments are susceptible to gross tabulations only, not to the kind of analysis necessary for pinpointing problems of specific age, socioeconomic, or geographic groups, or for measuring success or failure in meeting them.

Working Group on Service Programs

While counts of certain acts of the health department staff describe the efforts being expended for each separate program, they give no indication of what has happened as a result of the service. Although a number of health departments have recently revised their systems of compiling service statistics, no widespread agreement has been reached regarding the kind of statistical information that is most essential for the planning, operation, and evaluation of public health programs. Neither has there been any generally accepted guidance concerning the minimum amount of such information required and the kinds of breakdowns or relationships which are apt to be most generally useful.

It is to such problems that the Working Group on Service Programs—one of six working groups of the Public Health Conference on Records and Statistics—has addressed itself. The Working Group on Service Programs, until 1954 known as the Working Group on Service Statistics, is interested in data that describe and measure public health services to individuals and efforts to reduce environmental

4. Control of bovine brucellosis should be undertaken with aids recognized and available.

5. Measures should be taken to insure pasteurization of milk. The importance of pasteurization cannot be overstated; it kills *Brucella*. In areas where cow's milk is adulterated with goat's milk, this procedure must be carefully supervised.

6. Reliance on pasteurization alone, without regard for other routes of transmission, is unwise because most infections in many regions are spread by direct contact with infected animals.

7. Diagnostic reagents must be standardized and supplied by a central laboratory.

8. The manufacture and distribution of vaccine made with *B. abortus* strain 19 must be under constant control, preferably by a State or national health or agricultural agency.

9. The official brucellosis eradication program should, whenever and wherever practical, be supervised by full-time State, preferably public health, veterinarians, cooperating with livestock sanitary officials.

10. Serious consideration should be given to adoption of regulations that permit importation only of official calfhood-vaccinated animals over 30 months of age and under 36 months of age, provided the blood test within 30 days of shipment does not disclose a reaction exceeding incomplete in a dilution of 1:200.

11. A brucellosis center, devoting all its efforts to the development of an effective vaccine against caprine brucellosis, should be established in one of the Latin American countries. A committee of experts studying the immunology of this infection should be invited to serve as advisers.

Basic Principles Governing Service Statistics in Public Health

The following principles should govern the collection, tabulation, analysis, and interpretation of service statistics:

Principle 1

Service statistics should serve one or more of these purposes:

- Help define the health problems of the community.

- Help measure extent of the program.

- Help measure progress in relation to problems.

- Help furnish a basis for future program planning.

- Help provide data required periodically by the general public, local appropriating bodies, and State and Federal health agencies contributing financial aid.

Principle 2

Information accumulated for service statistics should meet the following tests:

- Should be not only useful but actually used.

- Should be valid.

- Should be significant for the purpose it is supposed to serve.

- Should be readily available.

- Should justify the time and expense involved in its collection.

It is recognized that accepted criteria for tests of validity and significance of certain types of information are not available at present. Establishment of such criteria is a project in itself and one which should be undertaken as early as possible in order that the importance of the utility factor could be judged against the importance of the availability factor.

Principle 3

In order to be most meaningful, service statistics should be related to baseline data. Examples are:

- Demographic information, such as population by age groups, natality, morbidity, and mortality information.

- Information regarding the housing, sanitation, nutritional, and general economic status of the community.

- Health needs of special groups.

- Information describing health facilities, services, and personnel available, under public, voluntary, and private auspices.

- Information reflecting expenditures.

Definite provision should be made for correlating baseline data with the service statistics accumulated. Too frequently, while the several bodies of information are available, there is no organized method by which they are brought together.

Principle 4

The most important concept concerning service statistics is that such statistics should, generally speaking, measure services directed to individuals and their environmental hazards, including results attained, and not attempt to measure staff activities.

Report of the Working Group on Service Programs, essentially as approved April 27-29, 1955, by the Public Health Conference on Records and Statistics, Washington, D. C.

hazards. Problems of registration and legislation pertaining to vital events are being considered by the other working groups of the conference—the working groups on (a) marriage and divorce, (b) methodology, (c) model legislation, (d) mortality, and (e) natality and fetal death.

The Public Health Conference on Records and Statistics was established in 1949 for the development and improvement of public health records and statistics. Membership of the conference is made up of representatives of vital and public health statistics programs of each State and Territory. The National Office of Vital Statistics serves as secretariat to the conference, and representatives of Federal and voluntary health agencies and of schools of public health participate in working group activities.

The several working groups engage in a year-round work program, which includes performance of basic studies, preparation of technical reports, and formulation of recommendations for consideration and action of the conference. Particularly significant to the guidance of effective public health action and measurement of progress are several documents which have been developed by the Working Group on Service Programs. These statements or guides have evolved from the experience and needs of the working group members and their colleagues from program divisions in the several health departments represented. In reaching its conclusions, the group has had continuous consultative service from professional leaders in the respective subject matter areas to which attention has been directed.

Meaningful Service Statistics

In order to make the conclusions of the working group widely available to public health

workers, *Public Health Reports* is publishing the series of technical reports designed to improve the quality of public health service statistics. The first report, "Basic Principles Governing Service Statistics in Public Health," follows on p. 521. This initial document proposes a number of fundamental concepts which the Working Group on Service Programs believes are essential to the development of meaningful service statistics in public health. The principles enumerated will be useful to many health departments as criteria for determining the value of program statistics being produced currently or contemplated for the future.

Guides for application of these basic principles to two specific types of health programs have also been completed. Entitled "Health Supervision of Infants and Preschool Children" and "Health Services for Children of School Age," they will be published in subsequent issues. As similar guides are developed for additional program areas and are approved by the conference for publication, they too will be released through *Public Health Reports*. A guide for home accident prevention programs is nearly completed.

These statements are in no sense an attempt to standardize either content or procedures in the development of service statistics. Prescribing specific statistical patterns which would be applicable to all health departments is neither desirable nor possible. On the other hand, a sound, widely accepted framework within which each health department may develop a program in accordance with its own particular needs and resources is badly needed for more effective program planning, operation, and evaluation. The conference believes this series of guides will contribute to that end and that each statement merits extensive study and application by public health workers.

maternity services can be obtained by relating antepartum, delivery, and postpartum services to the women who were delivered within a specified period than by getting unrelated counts of the three types of services.

Shown below is a pattern which relates service statistics for a tuberculosis screening activity to the problem, specifically, the number screened to the population concerned:

- Total population screened.
- Percentage of population screened.
- Number of persons screened.
- Number of films read.
- Number of persons referred for large X-ray.
- Number receiving large X-ray.
- Number referred to physician.
- Number of referrals completed.
- Number diagnosed as active.

By such relationship of information, the number for whom rechecks were recommended, the percentage of individuals tested who had evidence of a disease, and the number confirmed by private physicians provide a guide to the validity of the test. The number for whom rechecks were recommended and completed is an indication of the adequacy of followup. Reporting on this basis makes possible good comparison of services between various areas and between selected periods of time.

Principle 6

Unduplicated counts of individuals receiving service is useful information to local health departments.

"Unduplicated counts of individuals" means counting only once, for a designated period of time, each separate health department client irrespective of the number and variety of health department services he receives. It is possible that a person receives more than one service from the department. In considering total volume of service given by the health agency, such a person would be counted several times. For some purposes this is desirable and important information. However, in planning, operating, and evaluating a public health program, it is also important to know the number and characteristics of each individual served by the health department. Consequently, arrangements should also be made for counting only

once each person served by the health agency. In this connection, it is also important to know where the remainder of the community received comparable services, if any. These data can then be related to the population concerned and thus assist in measuring the extent to which public health effort is reaching all the people.

Principle 7

Service statistics as here discussed should, for the most part, be a byproduct of administrative operation of a program.

Maintenance of records and compilation and interpretation of statistics should be an integral part of program management. Case records of individuals served by the health department constitute the best source of service data in a well-conducted department.

Principle 8

To promote the use of selected information from case records, the basic record system should be so designed that pertinent items can be related without the necessity of searching through scattered sources.

The record being used should permit easy recording and review of the information it contains. One possibility of achieving this end is a single case record for each client, on which is recorded all types of service rendered by the health department. The record should also be readily accessible for review after it is filed. Such a record system must be worked out within the circumstances of individual health departments.

Principle 9

A review of the service record for each individual under health department supervision should be made regularly, at least annually, by the supervising staff.

Case record analysis can be limited to stated times: quarterly, semiannually, or annually. Periodic review reduces handling and permits

Major emphasis should be placed on the number of persons served and types and amount of service received, and not on numbers of visits and inspections made or other such measures of volume of staff activities.

Principle 5

In general, activity counts should not be used for service statistics.

The gravest criticism of utilizing activity counts for service statistics is the fact that a false sense of accomplishment may be engendered in health department personnel. When so many activities are recorded, there is severe temptation to think that every minute of the working time should be tabulated as evidence that full time and attention have been accorded the job. This leads to the desire to account for every letter answered, telephone call made, and even the time spent in preparing the activities report itself.

For example, items such as meetings attended as a part of duty, newspaper articles prepared, hours spent working on records, conferences with clerical personnel, attendance at professional meetings, special meetings attended, and similar activities may have administrative value to the supervisor or the program director in evaluating the distribution of staff activities, but they do not contribute directly to the measurement or evaluation of program services.

Likewise, the effectiveness of an educational program cannot be measured by number of pamphlets distributed, films shown, talks given, and so forth. Attendance at a meeting or carrying away of literature may have no relation whatsoever to what the individual learned through contact with the health information.

These questionable types of service statistics, enumerating the multitude of activities of health personnel, arise from attempts to get quantitative indexes of how much is being done in this or that program. However, mere counts of activities, without being related to the need or unmet demand for a service, add very little to knowledge of the problem or to program planning.

For example, the important thing to know in connection with immunization is the level of

immunization in the community. Counting up the number of immunizations given at specified places falls far short of giving that essential knowledge.

For measuring the amount of work done, gross counts will be meaningful only for activities expressed in standard work units, such as tuberculin tests, X-rays, clinic hours held, sputum examinations, and the like. For such activities as medical consultations, medical social work, or nursing visits, they will not be meaningful unless the content of the service is specified.

For supervision, counts of activity may be useful where work can be measured on a production basis, such as laboratory examinations made or X-ray film taken. On the other hand, when work to be evaluated is of such nature that it cannot be described in easily measurable work units, this type of information lacks validity since many factors besides numbers of activities participated in are important. A mere count of activities performed reveals neither the quality of service rendered, the time required, nor the results obtained.

For informational and budgetary purposes, such counts of activities have little meaning unless expressed in terms of progress toward a goal and of comparison with known needs and with standards for service. For determining relative emphasis placed on different segments of the program, enumeration of activities is revealing only for those parts of the program which are comparable.

As an example, a count of nursing visits or admissions for two programs cannot be considered a valid comparison of relative emphasis if one program consists of clinic and home nursing services and the other is carried out through home nursing visits alone.

The more valuable service statistics—those measuring services to individuals and the improvement of their physical environment—are based on counts of the patient load according to whatever breakdowns are significant (age, sex, race, residence, and so forth) and to the categories and amount of service received, grouped so that service is related to problem. Such data are needed for both program planning and evaluation.

For example, more useful information on

Evaluation in Public Health

THE First National Conference on Evaluation in Public Health evolved from a need for pooling the experience of the many individuals and groups concerned with evaluation of public health activities and stimulating the development of more effective evaluative techniques. Dr. Vlado A. Getting, professor of public health practice, School of Public Health, University of Michigan, was chairman of the planning committee. He opened the conference by stating its two main objectives: to bring together the work of many in the evaluation of public health so that all may profit; and to determine which steps logically might be taken next to improve the practice of evaluation of public health activities.

Background

Indirectly, the conference was an outgrowth of a recommendation made in 1953 by the Association of State and Territorial Health Officers:

"That a joint committee be established, representing the Public Health Service, Children's Bureau, and the Association of State and Territorial Health Officers, to develop quantitative and qualitative measurements which could be used to evaluate public health programs."

The First National Conference on Evaluation in Public Health was held at the School of Public Health, University of Michigan, September 12 and 13, 1955. This summary of the recommendations of the conference and some of its discussions was prepared by the Division of General Health Services, Bureau of State Services, Public Health Service, at the request of the conference's planning committee.

More immediately, it resulted from a meeting called in Buffalo, N. Y., on October 10, 1954, by the chairman of the association's representatives to the joint committee, Dr. J. D. Porterfield, director of the Ohio State Department of Mental Hygiene and Correction. In addition to the representatives of the Federal agencies and the State health officers, there were representatives from several organizations, which had planned or initiated studies concerned with evaluation of public health activities.

A planning committee was appointed to convene a 2-day working conference to learn more of what each group is doing and to develop a cooperative plan in which the various individual contributions could be dovetailed for the maximum contribution to the development of quantitative and qualitative measurement in public health practice.

Membership of the planning committee comprised representatives of the American Public Health Association, the Association of Business Management in Public Health, the Association of State and Territorial Health Officers, and the Children's Bureau and Public Health Service of the Department of Health, Education, and Welfare. These five agencies, in cooperation with the University of Michigan School of Public Health, sponsored the First National Conference on Evaluation in Public Health.

Structure

The conference was designed to enable the participants to discuss methods of evaluation as they applied to one of five specific health activities. A maximum of 20 persons participated in the discussions of each section. Participants were selected on the basis of their demonstrated interest in evaluation, and they were chosen from a wide range of professional

more thorough analysis. Such a review would require for each individual service:

- A plan.
- The existence of standard criteria of service (nursing, clinic, medical, social, rehabilitation, and so forth).
- A comparison of performance as revealed in the record against the plan and the criteria of service.

Periodic review of each individual service record would provide valuable leads to evaluation of the adequacy of health department service. An accumulation of unmet needs would reveal where emphasis should be put and would indicate needs for and distribution of personnel.

For example, if an analysis is made once a year of all known tuberculosis cases to determine how many tuberculosis patients are in the hospital, how many at home, the sputum status of those at home, and the number of tuberculous individuals at home who were last examined more than a year ago, attention is focused on a specific problem and on the health department's success, or lack of it, in keeping individuals under supervision.

If, in addition, records of all new tuberculosis cases are examined to determine the stage of the disease, and the age of the patient, attention will be drawn to the success of case finding.

A summary of this type of data provides appropriating bodies with a better understanding of the health department program and its needs than does the traditional count of visits, inspections, and admissions to broad categories of service. It is recognized that information from records needs to be supplemented by personal observations and knowledge of the person doing the job.

Periodic case record analysis would be less expensive and more valuable than the accumulation of a vast quantity of uninterpreted data, which is still a wide practice among public health agencies.

While compilation of service statistics by periodic case record analysis has been initiated in several places, it has not been extensively developed. Even when such types of data are collected, the resulting tabulations are too frequently not used and are not coordinated with operation of the program.

Review procedures should provide a mechanism for closing out the records of individuals no longer needing service or for determining priority of those needing service.

Principle 10

In order that only pertinent data be collected and that there be no duplication either of effort or data, health departments should have a committee for the development, review, and control of basic records, forms, and procedures.

In State health departments, the committee described above should include at least the director of local health services and representatives of the statistical unit, selected programs, and local health department. At either the State level or the local level, personnel who actually use records and interpret procedures should participate in their design and assist in establishing procedures for their use.

• • •

The basic principles have been reproduced in mimeographed form as Document 353 of the Public Health Conference on Records and Statistics by the National Office of Vital Statistics, Public Health Service, Department of Health, Education, and Welfare, Washington 25, D. C. They have the endorsement of the following organizations: Association of State and Territorial Directors of Local Health Services; Council of State Directors of Public Health Nursing; Statistics Section and Committee on Administrative Practice, American Public Health Association.

Evaluation in Public Health

THE First National Conference on Evaluation in Public Health evolved from a need for pooling the experience of the many individuals and groups concerned with evaluation of public health activities and stimulating the development of more effective evaluative techniques. Dr. Vlado A. Getting, professor of public health practice, School of Public Health, University of Michigan, was chairman of the planning committee. He opened the conference by stating its two main objectives: to bring together the work of many in the evaluation of public health so that all may profit; and to determine which steps logically might be taken next to improve the practice of evaluation of public health activities.

Background

Indirectly, the conference was an outgrowth of a recommendation made in 1953 by the Association of State and Territorial Health Officers:

"That a joint committee be established, representing the Public Health Service, Children's Bureau, and the Association of State and Territorial Health Officers, to develop quantitative and qualitative measurements which could be used to evaluate public health programs."

The First National Conference on Evaluation in Public Health was held at the School of Public Health, University of Michigan, September 12 and 13, 1955. This summary of the recommendations of the conference and some of its discussions was prepared by the Division of General Health Services, Bureau of State Services, Public Health Service, at the request of the conference's planning committee.

More immediately, it resulted from a meeting called in Buffalo, N. Y., on October 10, 1954, by the chairman of the association's representatives to the joint committee, Dr. J. D. Porterfield, director of the Ohio State Department of Mental Hygiene and Correction. In addition to the representatives of the Federal agencies and the State health officers, there were representatives from several organizations, which had planned or initiated studies concerned with evaluation of public health activities.

A planning committee was appointed to convene a 2-day working conference to learn more of what each group is doing and to develop a cooperative plan in which the various individual contributions could be dovetailed for the maximum contribution to the development of quantitative and qualitative measurement in public health practice.

Membership of the planning committee comprised representatives of the American Public Health Association, the Association of Business Management in Public Health, the Association of State and Territorial Health Officers, and the Children's Bureau and Public Health Service of the Department of Health, Education, and Welfare. These five agencies, in cooperation with the University of Michigan School of Public Health, sponsored the First National Conference on Evaluation in Public Health.

Structure

The conference was designed to enable the participants to discuss methods of evaluation as they applied to one of five specific health activities. A maximum of 20 persons participated in the discussions of each section. Participants were selected on the basis of their demonstrated interest in evaluation, and they were chosen from a wide range of professional

disciplines: medicine, nursing, engineering, dentistry, sociology, administration, and psychology.

The plenary orientation session was followed by simultaneous sessions of the five sections. Section discussions were related to selected specific programs: tuberculosis control, fluoridation of water supplies, accident prevention, prematurity, and cancer control. These specific topics encouraged the consideration of concrete examples of methodology. Discussions were aimed at bringing out the component processes of evaluation which might, or might not, be common to other public health practices.

Digests of the section discussions were summarized by a resolving committee chaired by Dr. Herman E. Hilleboe, commissioner of health of New York State. The committee's summary report was presented at the final plenary session for discussion and action by the entire conference.

Planning—Anderson

The keynote address for the conference was delivered by Dr. Otis L. Anderson, chief of the Bureau of State Services, Public Health Service, whose formal topic was planning in relation to evaluation.

Dr. Anderson posed two basic tenets: first, that planning for the evaluation of a program should be interwoven with planning for the program itself; second, that evaluation techniques should be applied in the improvement of planning.

He enumerated the several successive phases of program planning, viewed in its broadest sense, as follows:

1. Determination of specific problems or needs.

2. Delineation of long-term and short-term goals or objectives.

3. Assessment of resources available or obtainable, including public opinion, professional attitudes, and degree of cooperation which might be expected; funds; personnel; facilities; technical knowledge, and so forth.

4. Selection of program methods or activities to be used to gain objectives.

5. Continuous or periodic evaluation of achievement or progress toward attainment of

short-term and long-term goals—both quantitative, or measurable, and qualitative, or judicious appraisals.

6. Change in goals, redirection of program, or replanning, as indicated by accomplishment, by concurrent shifts in circumstances, improvements in useful knowledge, and altered resources.

7. Evaluation of final results.

Built-In Evaluation

In this pattern of program planning, the speaker explained that evaluation is built right into the plan as an identified, integral part. Evaluation cannot be considered an adjunct to public health program development, to be pursued or omitted as convenience dictates. It must be involved as an essential ingredient of program design, serving a definite purpose. Dr. Anderson demonstrated the application of this concept to a number of specific programs.

Every phase of positive program planning contains an element of evaluation, he said. Assessment and judgment are involved, and decisions must be made whether we are determining the extent of a problem, public opinion, resources available, or completeness of technical knowledge or whether we are establishing objectives or choosing methods for action geared to achieving the objectives. Each decision depends upon considering and choosing among alternatives. This weighing of evidence throughout the planning process is an informal, almost subconscious type of evaluation—but evaluation, nonetheless. Often, by careful analysis, it is possible to identify important related facts of which we had not been aware, thus “firming up” a base for our decisions.

Only when evaluation is built in as one dimension of program planning will it assure that proper provision has been made for validly appraising the success or failure of the program and that there is guidance for reconsideration of objectives and redirection of program, as such changes are indicated. Through prompt adjustment of program, much effort and expense that otherwise might be wasted can be saved. Available resources can be rechanneled without delay into more productive and more needed activities. Unless this is done, the program plan becomes static and sterile, and

completely valueless as an administrative tool.

For any program, Dr. Anderson said, there is a better chance of achieving long-range objectives if planning provides for progress evaluation of intermediate steps and of objectives at frequent intervals. Such evaluation yields immediate results. Concurrent evaluations make it possible to identify difficulties or barriers as they occur and to apply necessary adjustments.

On the other hand, if evaluation is delayed until objectives are achieved, the program may never be evaluated. Or if the appraisal is arbitrarily timed—in connection with a reorganization or a change in administration—we may find that for a long time we have been engaging in fruitless endeavor, and that the advance in measurable program achievement, the end and aim of program planning, has not been accomplished.

Need of Evaluation—Kandle

Dr. Roscoe P. Kandle, deputy commissioner of health of New York City, talking on the need and place of evaluation in public health, urged that a fresh start be made in the evaluation of public health practices, with renewed ambition and new perspectives. The public health profession is now on "dead center" with respect to evaluation in public health, he stated.

He praised the work of past years by the Committee on Administrative Practice of the American Public Health Association, supported by the Commonwealth Fund and by other groups, in developing various methods of appraisal and evaluation of specific public health techniques. He also noted outstanding current work, such as that in evaluating several methods of tuberculosis control, in pinpointing specific causes of infant mortality and in appraising the effectiveness of efforts to reduce these problems, in carrying out precise studies of diagnostic tests and practices for control of coronary disease and hypertension, and in developing new methods and formulas for determining the number of public health nurses needed for adequate service to a community.

Nevertheless, the evaluation of widely used public health practices remains a major weakness, Dr. Kandle stated. Growth of programs has outstripped our ability and ambition for

appraisal. He directed attention to several barriers which have not been penetrated successfully:

1. There is a strong tendency to think of effort rather than of accomplishment. There are not many practical indexes of accomplishment.

2. There is a lack of true perception and precise knowledge of people's actions and beliefs about health and the changes we are trying to encourage them to make. To evaluate without taking into account the factors of the people's understandings and feelings is foolish and wasteful.

3. It is difficult to devise simple, practical evaluation procedures which can be built into everyday practice.

4. We are apt to conform too rigidly to narrow public health traditions. This produces stereotyped thinking, which limits critical, incisive analysis of our accomplishments and fresh and original approaches to our problems.

Report of Resolving Committee—Hilleboe

The extent to which the conference attained its objectives is reflected in the summary report of the Resolving Committee which was presented by Dr. Hilleboe.

Dr. Hilleboe reported that he found many similar opinions among the representatives of the five sections. He emphasized that when evaluation in public health is discussed, there must be understanding about what is to be accomplished. Accordingly, a program is needed. We also must have a plan of operation which is, of course, based on the program plan. If we evaluate what we are doing in the light of what we set out to do, then we are moving in the right direction, he said.

We can evaluate a technique, a research project, a study, an activity, an objective, a purpose, or a total program, Dr. Hilleboe continued. We need to evaluate the yardsticks, the tools of measurement, themselves. It is also true that we can do some administrative evaluation, and its importance in carrying out all of our public health programs should not be forgotten. We can evaluate both performance and measures of performance; ultimately, we must evaluate performance against our stated objectives.

This basic principle came out time and again in many of the sectional discussions, Dr. Hilleboe reported. Highlights of the rest of his report included the following:

It is possible to become so absorbed in one particular technique that an undue amount of time is spent in evaluating that single technique. Sooner or later we must determine the value of the technique to the activity in which it is used. The activity in turn must be related to objectives, and they, in turn, to the purpose of the entire program.

Evaluation in public health becomes meaningful when it originates from a critical attitude of mind and intellectual curiosity. Those are fundamental ingredients. Program evaluation requires the same meticulous skills and methodology that the epidemiologist employs in the study of an acute or chronic disease. It is not enough to make measurements; what is needed is the measurement of results. Reliable and valid techniques can produce measurable results if expertly used. Precise evaluation studies are really research projects of one kind or another, and are quite similar, in fact, to the epidemiological field studies made by health department personnel. Both use the scientific method to obtain unbiased results.

The evaluation process should employ scientific measurement and comparison in public health practice as in other fields. Certainly the public health profession should use a scientific method whether it is in administration, or the evaluation of a technique, or the activities or programs that make up the substance of public health. Evaluation studies to be sound require appropriate samples.

In evaluating techniques, reliability, validity, yield, cost, and acceptance, must be measured. But when objectives and programs are considered, the factors of adequacy and efficiency must be added to our evaluation. Cost must be taken into account because all program plans depend upon money for continued operation. It is essential to determine if the evaluation is going to be worth the time, effort, and money spent in relation to the limited resources available for all health department work.

The human factor must be recognized in the evaluation process. Suggested changes in program content and direction may threaten the

security of the individuals concerned, so evaluation must consider human relations in public health.

The several sections of the conference are in general agreement. One of the strong currents running throughout the whole discussion was the feeling that there is considerable value in exchanging ideas and experiences on evaluation, that the conference has been profitable, and that constructive, definite recommendations resulted.

It appears that the initial need is to have a small group, perhaps taken from this conference, start work on developing acceptable and unified terminology and definitions. This will enable public health people to communicate with each other more easily and precisely and to talk more profitably about evaluation.

Many of the health organizations represented here, both public and private, can look at some of their programs to see if some new evaluation projects can be set up. Within the next 12 months some evaluation projects could be started where they have not been carried on before. Every full-time health unit can begin some evaluation work even if it is only the testing of a minor technique or administrative procedure. It is up to us to find the resources within our own departments and do something in evaluation that we haven't done before. Then we can communicate with one another and exchange information of mutual benefit.

There should be another conference of this type, in about a year, to which all of us can bring the results of our new evaluation projects for open discussion. Prior to the proposed conference, copies of reports of projects can be distributed so that criticism and discussions of these evaluation projects may be more concentrated when we do convene. This would lead naturally to still further evaluation.

From our intense discussions of the past 2 days have come principles and practices in evaluation which can be useful to many health workers throughout the world. To set up a clearinghouse on evaluation in public health would be a natural followup, one which would enable all to keep abreast of present and future development in this field. It would provide for continuous exchange of experience and other information, and duplication of effort in pur-

suing the same types of evaluation might be avoided. Thus we would get the greatest benefits possible out of the human effort and the monetary expense involved.

Such a course of action may well herald a new and exciting era for public health in a changing world.

Conference Action—Witmer

Discussion of the Resolving Committee's report was opened by Dr. Helen L. Witmer, director of research, Children's Bureau, Department of Health, Education, and Welfare, who emphasized that difficulty in keeping on a straight track in planning for program evaluation arises from the fact that programs are so complex. She likened them to social institutions which, she said, can easily be divided into their component parts: purpose or objectives; personnel and clientele; rules—legal, ethical, technical (instruments, procedures, techniques); and equipment—facilities, including money activities.

One of two pertinent questions might then be asked regarding each element:

1. Is it scientifically valid? (Does the kind of staff, equipment, and procedures used lead to the desired results?) or

2. Is it good (the staff or the results) according to accepted standards?

Ideally, standards should be based on scientific validation. When this is not possible they must be based on judgment and experience. The main thing in planning and carrying out evaluation is clarity of purpose and direction.

Most of the audience discussion pertained to the recommendations proposed by the Resolving Committee. The final action of the conference was the adoption of the following recommendations:

Copies of the full Proceedings of the First National Conference on Evaluation in Public Health may be purchased from the University Publications Distribution Service, 311 Maynard Street, Ann Arbor, Mich.

The clearinghouse function recommended by the conference has been delegated to the Subcommittee on State and Local Health Administration of the Committee on Administrative Practice of the American Public Health Association. Forms for registration of projects may be obtained from Dr. Vlado A. Getting, chairman of the subcommittee, whose address is School of Public Health, University of Michigan, Ann Arbor, Mich.

1. That a small group be designated to develop uniform, acceptable terminology for general use in public health evaluation. (This recommendation was prompted by the fact that all groups reported that confusion concerning terminology had characterized and hindered their discussions.)

2. That each health agency represented start some evaluation project within the next 12 months and carefully document the methodology used.

3. That another conference be held within one year for the purpose of reviewing the projects and determining methods and techniques which could be used by other agencies.

4. That a clearinghouse be established for continuous exchange of experience and prevention of duplication of effort in the development of methods and criteria for evaluation.

5. That the necessary staff and financial support be obtained to set up this central agency on evaluation.

Practical Nurse Training in the Home

By MARTIN CHERKASKY, M.D., ELIZABETH B. TORRANCE, M.A., R.N.,
ELSIE BANDMAN, M.A., R.N., and BETTY SEIFMAN, M.A., R.N.

THE INCREASE in chronic disease has created a host of problems. These derive not only from the mounting number of chronically ill patients, but also from the long duration of chronic disease and the associated emotional, social, and economic disorders that affect both patient and family.

The changing character of illness is shown by reports from visiting nurse agencies throughout the country that their services are devoted more and more to patients with chronic disease. The Visiting Nurse Service of New York reported that in a recent 6-month period 70 percent of the visits were to patients with long-term illness.

Because chronic illness is measured in months and even years, it has become neither desirable nor possible for all the chronically ill to be cared for in hospitals, certainly not for the major period of illness. This consideration has caused many changes in the patterns of medical care (1).

Montefiore Hospital, New York City, recognizing the impossibility of providing institutional facilities for all the chronically ill and the undesirability of keeping many patients in

institutions rather than in the home with their families, embarked in 1947 upon its home care program. Techniques of providing comprehensive care to patients in the home were fully explored and have in many instances served as the pattern for home care programs throughout the country as well as abroad (2). Of particular significance throughout the United States is a growing number of organized programs of home care designed to meet the complex needs of chronically ill patients within the framework of the home (3-9).

It is fortunate that this necessity has considerable virtue. Montefiore has demonstrated that, for properly selected patients, home care is a method of choice when the basic team of the physician, nurse, and social worker is available to meet the multiple needs of the patient and his family. Of these three, none is more important in this service than the nurse.

The rise in chronic disease, which will assuredly continue, has led not only to a shortage of institutional facilities but to an even more serious shortage, that of nursing personnel. The American Nurses Association reported that there were 389,600 active professional workers at the end of 1953. Of these 231,000 were professional nurses employed in the field of hospital and institutional nursing. An additional 54,123 practical nurses were also employed in that field (10).

Although this was the largest number of professional nurses who had ever practiced in the country, the demand has kept well ahead of the supply. One of the reasons for this demand is the enormous growth of hospital facilities. In 1934 the total number of hospital beds in this

Dr. Cherkasky is director, and Miss Torrance is nursing executive, of Montefiore Hospital in New York City. Miss Bandman, formerly supervisor of the hospital's demonstration project for practical nurse training in the home, is now assistant nursing executive of the hospital's School of Practical Nursing. Miss Seifman succeeded Miss Bandman as supervisor of the demonstration project.

country, excluding those for the mentally sick and tuberculous, was 464,193, and in 1953 it was 735,215 (11).

In 1940, hospitals pressed by the growing demand of the armed forces for nursing personnel further developed a new hospital worker—the trained practical nurse. Today, patient care would be impossible in many of our hospitals were it not for the trained practical nurse, at first accepted only grudgingly by her colleagues and others in the health field. Her period of training, in contrast to the minimum 3 years for the professional registered nurse, is approximately 1 year. To qualify for practical nurse training at Montefiore Hospital, the student must have certain qualifications:

Age: 17-50.

Education: Elementary school diploma or its equivalent.

Health: Applicant must have good physical and mental health and moral character. Medical and dental records must be filled out by the applicant's own physician and dentist on a form provided by the school.

Selection: An admissions committee makes the final selection, based upon an evaluation of the applicant by personal interview, preentrance testing, and references.

Obviously the pretraining qualifications and the length and extent of training preclude the average practical nurse from assuming the same range of responsibility as the professional nurse. There is, however, no question that, with proper selection of students and a year of carefully planned and supervised training, the practical nurse is prepared for a wide range of nursing services which supplement and complement the services of the professional nurse.

In view of the great problem of chronic disease and the growth of home care programs, it is inevitable that a considerable part of the burden of nursing care in the home, as well as in the hospital, will have to be carried by the trained practical nurse.

The Questions

In 1952, Montefiore Hospital approached the New York Foundation with a request that it support a 2-year research program designed to answer the following questions:

Without major changes in the length of the curriculum, what are the functions and services which the practical nurse is best prepared to carry out for the sick person in the home? What is the role of the practical nurse in the home on her own; as a member of an organized home care team; or as a member of a visiting nurse service? How much of the training year should be devoted to training in the home? What should be the nature of the training in the home? In addition to training in the home, what changes are desirable in the basic curriculum of practical nurse training which will enable her to do the best job in the care of the sick at home? What is the cost of such a program?

One of the conditions making our situation particularly suitable for this practical nurse demonstration was the close and vital relationship that had been built up in the preceding 5 years between the Montefiore department of home care and the Visiting Nurse Service of New York, the agency under contract for service to Montefiore home care patients (12). A VNS supervisor has also acted as nursing consultant to the program.

With an extensive experience in chronic disease, with a home care program carrying an average census of about 85 patients, with a well-established school of practical nursing, with a close tie to the Visiting Nurse Service, and, above all, with the philosophy of the team approach to the care of the chronically sick, the Montefiore Hospital division of social medicine was chosen for this project.

Program Description

The study was scheduled for October 1, 1952, to October 1, 1954. A full-time supervisor was employed for student orientation, teaching, and general administration of the study. And a contractual agreement was drawn up to cover the care of patients under the joint service of the hospital and the Visiting Nurse Service of New York.

During the 2-year period, 159 students in the Montefiore School of Practical Nursing received a 3-week period of training in the home of patients after basic work in medical and surgical nursing. The average number of stu-

dents in the program at any given time was six.

A typical period will be of value in presenting some of the activities in the home. During the 6 months, January 1 to June 25, 1954, there were 8 training classes consisting of a total of 35 students who each received a 3-week course in home care. Table 1 shows the average student day during home training and table 2, the activities during the period.

The transition between work in the hospital wards in which a student practical nurse was assigned to limited responsibility for a specific patient to the increased responsibility for a patient in his home presented an educational challenge.

An orientation course of several hours was given to each student on her first day and was continued for as many successive days as needed. This course included statements explaining the philosophy of the home care department, its team approach, and its many patient care func-

tions. The aims and services of the Visiting Nurse Service of New York, as well as the cooperative agreement between the pilot study program and the Visiting Nurse Service, were discussed. Presented in detail were the specific responsibilities of the student to the patient as well as her relationship to the supervisor and to the physician. Modified procedures, such as home methods for sterilizing instruments and thermometers, were demonstrated. Approach to the patient, entry into the home, and attitude and concern for environmental deficiencies were explained. Finally, the individual patient, his physical ailments, and his emotional and social needs were discussed preparatory to the student's initial visit.

Throughout the experience, the student participated in, and contributed to, home care team conferences. Introductory visits to the patient were made jointly by the student and the visiting nurse. At this time, the student could observe the visiting nurse's approach to the patient and her procedures. This made subsequent contacts between the student and the patient more satisfactory. Followup visits were under the guidance of the pilot study supervisor until the student exhibited mastery of a given activity. Students also visited patients with home care physicians, occupational therapists, and physiotherapists, and observed a variety of advanced procedures ranging from thoracentesis to massage and exercise. They observed the staff's interchange of information, which had as its objective improved service to the patient and the family. In the home, students performed a variety of nursing procedures as well as essential homemaking activities.

The Answers

What is the role of the practical nurse in the home?

The practical nurse demonstrated during this study that she was competent and efficient in a patient's home. She was capable of performing a variety of nursing procedures ranging from a simple bath to sterile dressings, care of tracheotomy patients, administration of oxygen, and preparation of food for patients on regular and special diets. She was able to make necessary and frequently complex adjustments

of basic skills to meet individual needs in the home.

The practical nurse student, through her training in the home and family setting, developed appreciation of the patient as an individual and of the importance of family relationships in the care of the sick. Each succeeding visit increased her insight and her sensitivity to the emotional stresses and medical, nursing, and socioeconomic problems of her patient.

In a teamwork setting, the student learned the role of the physician and social worker and developed a clear understanding of her own function not only as a practical nurse, but also as a participant in the team. Personal contact between staff members and the practical nurse student fostered mutual respect and understanding. As a member of the Visiting Nurse Service team, she proved her value in effectively relieving the professional nurse of certain routine bedside nursing duties in a manner that was highly acceptable to the patient.

It is, however, important to remember that a 1-year period of training, no matter how excellent, is not designed to give the practical nurse opportunity to learn the many nursing procedures that the professional nurse studies in 3 years.

The advice of Marian G. Randall, executive director of the Visiting Nurse Service of New York, is pertinent: "Continue the excellent plan of teaching patient-centered nursing but give the student the added security of teaching her what she should not do in the home on her own, and of teaching her the signs and symptoms which indicate when she should ask for help and supervision. In the hospital there is always someone near, but in the home the nurse is without professional assistance and there is need to recognize the difference."

Preferably, the practical nurse after her year of training should work within the framework of an agency, such as a visiting nurse service, so that under supervision she may gradually assume greater responsibility in the home.

The Visiting Nurse Service of New York, for instance, employed three of the practical nurse graduates who had received home training, waiving on a trial basis the prerequisite of 1 year of graduate experience. After the VNS

supervisor became convinced of their capacity, the practical nurse graduates administered intramuscular injections to selected patients in addition to other duties.

How much of the training year should be devoted to training in the home?

At the outset and on a trial basis, we allocated 3 weeks of the curriculum for the home nursing experience. The first week was devoted largely to student orientation to the program. The program as a whole was discussed, case load assigned, travel directions given, patient care given, patients' case histories studied, and diagnostic signs and symptoms discussed. It was during this first week, too, that the student made, with the visiting nurse, an introductory visit to each of her patients.

The second and third weeks were devoted to assigned case loads under fairly constant supervision of the program supervisor. During this period the various problems that arose were discussed, case studies were written, and examinations given and corrected.

As we gained experience, the faculty concluded that despite a tight curriculum a home training program extended to 4 weeks would provide a broader learning experience. The student could be given more opportunity for independent practice, with supervision as required, and a longer period in which to develop initiative, resourcefulness, and judgment. The supervisor would have more time to evaluate the student's strengths and needs.

What is the nature of the training in the home?

Observations. The student practical nurse observed the visiting nurse giving care, which included subcutaneous injections and dressings. This was followed by the supervisor's discussion of principles involved in giving care.

Discussion and demonstration. The supervisor demonstrated modifications of procedures such as boiling instruments and cleaning thermometers. She then had the student demonstrate her grasp of these techniques. The visiting nurse shared with the practical nurse student some of the ingenious methods devised over the years which enabled her to work effectively in the home, such as: (a) care of equipment; (b)

improvised equipment, for example, bed rest and tray made out of cartons; slippers and wastebags made out of newspapers; paper padding in lieu of rubber sheeting.

Formal class teaching. Reading was assigned to students. Class discussion was held on specific illnesses and their signs, symptoms, and medication, all correlated to particular patients. Examinations were given, corrected, and reviewed with the students on an individual as well as a group basis.

Each student was assigned a particular patient for whom a written patient-care study was required. These patient-care studies were discussed and evaluated.

Conferences and seminars. The student attended the weekly home care conferences where patients were discussed. The students were free to ask questions. Frequently, a student's patient-care study was used as the basis for discussion at such a conference.

A 2-hour conference was held with each group of students and the occupational therapist. Here, the purpose of occupational therapy and patient suitability for occupational therapy were discussed. In turn, the students frequently called to the attention of the occupational therapist patients who seemed in need of such therapy.

At an orientation conference with the social worker, the students received further insight into understanding the patient as a person and a family member.

Scheduled informal conferences were held by the physical therapist with the students following home visits.

Homemaking duties. Homemaking duties, generally, were minimal. The student was primarily responsible for cleaning the bedside unit.

Since diet and preparation of food are included in the curriculum, the student was familiar with various types of diet, such as bland and salt-free. The program supervisor discussed in detail with each student the dietary requirements of her patients. She stressed the help the nurse could give the patient in understanding and continuing a diet which, while therapeutic, was sometimes quite unpleasant. Whenever necessary, the student prepared and

served a patient's food and did other minor household chores. It is interesting and significant that the practical nurse student was unenthusiastic about duties which were specifically homemaking.

What are the necessary curriculum changes?

The home care experience has resulted in a major reorientation of our curriculum. Not only has it improved the training of practical nurses so that they can function adequately in the home, but it also has sharpened our understanding of the kind of curriculum we require to train a practical nurse to function better in all responsibilities. Heretofore, the curriculum had been focused on mastery of subject matter and nursing procedures as isolated factual material. Even before the pilot study, the need for a patient-centered curriculum had begun to be apparent. In the pilot study, it became quite clear the student was having difficulty in integrating her learning and adapting it to each patient.

The first change was in the content and technique of presenting the more than 70 hours of "conditions of illness." Instead of teaching the major disease entities, the focus was shifted toward the patient with a disease in need of nursing care. All pertinent information relating to the disease—its etiology, symptoms, and treatment, including drugs and diet—was reviewed in the light of its contribution to effective nursing care. The patient's emotional needs and the devastating social effect of long-term illness also were integrated into the teaching program. Advanced nursing procedures, such as thoracentesis, paracentesis, and lumbar puncture, have been included in the conditions of illness course within their appropriate context, rather than presenting them as part of the nursing arts course. Ward conferences, including allied health personnel, revolving around a student's nursing plan for a specific patient have been helpful in training the patient-oriented nurse.

This orientation of the student nurse to the patient may seem so natural and right as to raise the question why it was not done before. Of course, in some measure it always has been done. The problem faced in nursing education parallels that of medical education. The focus of our teaching is so sharply directed toward

the multiplicity of facts and techniques our students must learn that we tend to forget the primary purpose of nursing education, which is care of the patient. It has been said that the technician has become both so skilled and so narrow that he knows everything about his job but its purpose. It is imperative that the attention of the student nurse be directed as positively to the entire patient as to any group of specific skills. Seeing patients as people and within a family setting is one of the best ways of accomplishing this purpose.

The second deficiency, that of lack of adequate information in the biological areas, has been remedied by another shift in the curriculum. This involved reducing the number of hours allocated to the domestic arts and the hygiene courses and increasing the allocation of hours spent on body structure and function and drugs and solutions.

Our concern with the curriculum is not ended, and it is expected that many more revisions will be made.

Cost of Program

The cost of the 2-year demonstration of home training for student practical nurses was \$16,293. A breakdown of the expenditures follows:

<i>Personnel</i>	\$11,300.65
Salaries.....	10,662.98
Perquisites.....	442.92
Social Security	194.75
<i>Student expense</i>	2,411.94
Transportation.....	1,492.83
Lunches.....	887.71
Telephone	31.40
<i>Other expenses</i>	1,189.17
Travel.....	161.02
Consumable supplies.....	828.15
Statistical service.....	200.00
<i>Miscellaneous and overhead</i>	1,392.14
Total expenditures.....	\$16,293.90

While it cost about \$8,000 a year to conduct this project on an experimental basis, it is likely that, as a routine part of a school for practical nursing, the same program could be conducted for no more than \$7,000 a year. This is encouraging since it seems quite obvious that the additional cost of including home care in the curricu-

lum will be within the means of most schools. It must be recognized, however, that one of the reasons for the relative inexpensiveness of this additional teaching activity was the presence of a well-organized home care program and a well-organized and cooperative visiting nurse service.

Conclusions

1. The practical nurse, with proper preparation during her training, can contribute effectively to the growing responsibility for care of patients in the home.

2. The practical nurse, with proper delineation of responsibilities, can supplement and complement the professional nurse.

3. To insure that the practical nurse is prepared for what will inevitably be her responsibility for care in the home (as well as in the hospital), the curriculum for her student training should be primarily patient-oriented. We feel this should include a 4-week period of training in the home, preferably within the framework of a well-organized home care program.

4. The sensitivity, compassion, and understanding, which are the hallmarks of the superior nurse, are not the result of training alone. In many instances, a practical nurse, properly prepared, can bring these attributes to the patient in the home or in the hospital, particularly if she is accepted as a member of the team along with the doctor, the social worker, and the professional nurse.

5. It is not difficult to insert within the curriculum the time necessary for home care, and the budgetary implications are not of such great moment as to make this financially impracticable, particularly if there is an organized program of home care and an effective and cooperating visiting nurse service. Continued experience in training practical nurses in the home and for the home should, and undoubtedly will, lead to further curriculum changes.

6. A program that brings the nursing department of a hospital and the staff of the school of practical nursing into the home has a very beneficial effect upon the attitudes and understanding of the top professional personnel. It is extremely difficult for professional workers to think about patients as whole people

in society when they are only seen in the narrow setting of an institution. Bringing the staff of the nursing school in close contact with patients, in their natural settings as members of the family in the home, cannot but favorably influence the training of the nurses in the same manner as this device is now being used to favorably influence the training of physicians (13).

• • •

NOTE: The Montefiore Hospital demonstration project, supported by a grant from the New York Foundation, is one of several programs sponsored by the National Association for Practical Nurse Education to determine the value of home care training in the practical nurse curriculum. A composite report including the experience of all the programs sponsored by the NAPNE will be published shortly.

Joint Services Sanitary Engineer Training Courses

The first joint training courses for reserve sanitary engineer officers of the commissioned services—Army, Navy, Air Force, and Public Health Service—were held in June 1956 at the Robert A. Taft Sanitary Engineering Center of the Public Health Service in Cincinnati.

Developed jointly by the Department of Defense and Department of Health, Education, and Welfare, in collaboration with the National Research Council, these courses are especially designed for reserve engineer officers normally on inactive status. The courses will bring them up to date on professional developments in sanitary engineering and will provide information on sanitary engineering emergency operations applicable to situations in natural disasters and in military and civil defense emergencies.

To plan an effective program for the control of gonorrhea, more understanding is needed of the clinical course of the disease, its epidemiology, and its response to treatment.

Unknowns and Enigmas in Gonorrhea

By IRA LEO SCHAMBERG, M.D.

THE dramatic reduction in the incidence of syphilis is one of the great achievements of the last decade. Since 1947, there has been a nationwide decrease of 93 percent in reported morbidity of primary and secondary syphilis (1). The striking reduction in the number of such patients reported from public health clinics, where morbidity reporting is most complete, as well as from private physicians, suggests that this represents a real decrease in syphilis morbidity.

Gonorrhea morbidity has not followed suit, as indicated in figures 1, 2, and 3. The purpose of this paper is to present a number of unanswered questions about this ubiquitous disease. Possibly, when some of these questions have been answered we may understand why gonorrhea is reacting so differently from syphilis to modern therapeutic and public health measures.

As Babione (2) stated in 1949, "The true in-

cidence of gonorrhea in the United States is unknown and virtually unknowable." He suggested determination of the ratio of gonorrhea to syphilis, a disease for which the incidence is known with greater accuracy, as an approach to a more valid picture of the frequency of gonorrhea. In his elaborate statistical study, he computed this ratio by age in the United States Navy for 1945 and suggested that this baseline may be used in the future in estimating changes of effectiveness of control measures applied to either gonorrhea or syphilis. The increasing difference in incidence which seems to have appeared between these two diseases in recent years would appear to make this method invalid.

Morbidity reporting of gonorrhea among civilians has always been faulty, and conclusions drawn from such data must be made extremely cautiously. Reporting by public health clinics is a great deal more accurate than reporting by private physicians. However, patients may, for a wide variety of reasons, such as employment, economic status, or convenience, transfer from clinic to private physician or vice versa. Therefore, conclusions regarding incidence based solely on morbidity reporting from public health clinics are also open to serious error (3). Reporting by the armed services is, in all likelihood, more complete than reporting by civilians, but there are, nonetheless, many deficiencies. Evidence bearing on the incidence of gonorrhea in the United States may be summarized as follows:

1. Gonorrhea trend analyses have been made

Dr. Schamberg is chief, section of venereal disease control, Philadelphia Department of Public Health; assistant professor of dermatology, Graduate School of Medicine, University of Pennsylvania; and chief, department of dermatology, Albert Einstein Medical Center, Northern Division, Philadelphia, Pa.

This paper was presented at regional venereal disease control seminars in Omaha, Nebr., Atlantic City, N. J., and Miami Beach, Fla., March 9 and 23 and April 20, 1955, respectively, and at the Symposium for Recent Advances in the Study of Venereal Diseases, Washington, D. C., April 29, 1955.

Figure 1. Primary and secondary syphilis and gonorrhea in the white male, 1941-54: rates per 100,000 population, continental United States.

Source: Morbidity reports, Public Health Service.

by the Venereal Disease Program of the Public Health Service (4). In reviewing data on gonorrhea cases among nonwhite males reported by clinics in 13 of the larger cities of the country during the period 1952-54, it was observed that some of the cities showed no change in numbers of cases reported; some showed a moderate increase; and some, a moderate decrease. No uniform trend was noted.

2. Analysis of the gonorrhea case rate for the United States from 1919 through 1954 (1) shows that the case rate per 100,000 population in 1954 (152) was slightly higher than in 1919 (148). The highest incidence in 1947 (284) may have been related in part to the policy of many health departments at that time of providing the then expensive penicillin free in return for morbidity reporting of venereal disease.

3. Review of venereal disease rates in the armed services reveals a decrease in syphilis (chiefly primary and secondary stages) in the Army of 85 percent, and an increase in gonorrhea of 11 percent from 1935 through 1953. In the Navy, syphilis decreased 98 percent, gonorrhea 70 percent (personal communication from the Surgeon Generals' offices, U. S. Army and U. S. Navy). The apparent decrease in gonorrhea in the Navy may be at least partly

explained by the fact that the 1935 figure applied to the entire Navy, the 1953 figure only to naval personnel within the continental United States.

From these data, because of the factors mentioned above, we cannot know for certain whether gonorrhea has increased or decreased in incidence. However, it appears improbable that there has been a precipitous decline in incidence such as has occurred in early syphilis.

Many practicing physicians with whom the author has talked have expressed surprise that there is no evidence of a marked decrease in gonorrhea incidence. They state that they now see only a very few patients with gonorrhea, whereas in the past they saw many such patients. They add that complications of gonorrhea, such as arthritis and epididymitis, are now rarities. This widespread clinical impression may be at least partly explained on the following bases:

1. In the presulfonamide days (before 1937), all types of gonorrhea persisted over a period of weeks or months. If one may estimate that in those days the average male patient with gonorrhea visited a clinic or physician 3 times a week for 3 months, he would have been seen approximately 40 times. Today, the male patient with gonorrhea need be seen only once to

Figure 2. Primary and secondary syphilis and gonorrhea in the nonwhite male, 1941-54: rates per 100,000 population, continental United States.

receive his curative injection of penicillin. This sharp decrease in the number of times patients with gonorrhea are now seen might be interpreted by the physician as a decrease in incidence.

2. Every general practitioner today is able to cure gonorrhea promptly. Therefore, many patients who previously were referred to clinics and specialists are now being seen only by the general practitioner.

3. A change in the character of gonorrhea in the course of the past 20 years may partly explain the great decrease in complications of gonorrhea.

4. Another explanation may be that the majority of individuals infected with gonorrhea are treated relatively early with penicillin, which prevents the development of complications.

It is probable that intensive public health control measures plus widespread use of penicillin for diseases other than syphilis are the factors chiefly responsible for the dramatic decline in syphilis. One would think that gonorrhea would be more susceptible to these measures than is syphilis. In the male, the incubation period is short, permitting time for in-

fection of few sexual contacts before symptoms appear, and symptoms usually bring the patient promptly to medical care. Transmission almost solely by sexual contact limits the number of exposed individuals. Penicillin cures rapidly and makes the patient noninfectious. In addition, for the past 2 years in many areas of the country, public health measures to achieve prompt treatment of female contacts have been carried out.

On the other hand, the brief incubation period can favor the spread of gonorrhea, as has been pointed out by Magnuson in a personal communication. Penicillin given fortuitously for an unrelated condition must be given during the incubation period of gonorrhea if it is to curb infectiousness more rapidly than will penicillin given for the disease itself. It is less likely that penicillin will be received coincidentally during a brief incubation period than during a long one.

The following questions come to mind.

Q. Does penicillin cure gonorrhea?

A. Love and Finland (5) have recently shown that the gonococcus has not developed resistance to penicillin in vitro in the period 1945-54. However, there is evidence that some or-

ganisms are most sensitive to penicillin when actively metabolizing and are significantly more resistant when in a quiescent state (6). Rees (7) states, "When the gonococcus lies in a closed or intermittently draining focus, it may escape the action of penicillin, and is a potential source of reinfection if the focus is reopened." "Failure" of penicillin to cure gonorrhea has been reported by a number of authors (8-13), and may usually be explained by one of the following factors:

1. Reinfection.
2. Inadequate dosage.
3. Destruction of penicillin by penicillinase.
4. Resistance of inactive gonococci in an unfavorable environment (6).
5. Too brief blood level (aqueous penicillin, exertion, hyperemia of depot, low renal threshold, and so forth).
6. Misdiagnosis (nonspecific urethritis, and so forth).

Q. How long is gonorrhea infectious in the untreated female?

A. No evidence is available, in view of the impossibility of differentiating persistence of infection from reinfection.

Q. What factors cause or favor development of gonorrheal pelvic inflammatory diseases (PID)?

A. Some theories, no factual knowledge.

Q. What percentage of infected females develop PID?

A. Lewis (14) believes that many escape.

Q. What is the time interval from infection to PID?

A. Wertheim, as quoted by Peters (15), is said to have found gonococci in the endometrium 5 to 14 days after sex contact. There are many conjectures, but no knowledge.

Q. In the woman with PID does a positive cervical or urethral culture result from the original infection which caused the PID or from more recent superinfection?

A. No data, but in view of the lack of immunity resulting from gonorrheal infection and difficulty in culturing gonococci in women with PID of long duration, the latter appears probable.

Q. Is the patient with PID infectious?

A. In a study of sexual contacts of men with gonorrhea, Goldstein (16) found positive cervical cultures in 35 percent of the women who had PID and in only 21 percent of those found free of PID (table 1).

Q. Are women with repeatedly negative cultures necessarily free of infection and noninfectious?

A. Lewis (14) and Rees (7) believe that intermittently draining cervical glands may permit a woman to be infectious from time to time despite repeated negative cultures. The male urethra may also be a more efficient sampler and culture medium than are the physician's swab and the bacteriologist's petri dish. Koch (17) found, in women with gonorrheal cervicitis, alkaline cervical mucus and a high percentage of positive gonorrhea cultures in the first half of the menstrual cycle, acid cervical mucus and few positive cultures from the 22d to the 25th day (table 1). Therefore, negative cultures late in the menstrual cycle would appear to give no assurance of freedom from infection.

Q. In the female, can persistence of gonorrheal infection, relapse, reinfection, and superinfection be differentiated?

A. To date, no.

Q. Does penicillinase inactivate penicillin locally and prevent cure of gonorrheal proctitis?

A. Hagerman (18) found a higher relapse rate in women with proctitis and suggested that penicillinase (produced by *Bacterium coli*) inactivates penicillin in the rectum. However, Bang (19) found no evidence to support this thesis. Many bacteria produce penicillinase, an enzyme which destroys the antibacterial action of penicillin, and Tacking (20) has shown that secondary infection by one of these bacteria may inhibit the action of penicillin against pathogenic penicillin sensitive organisms in vivo.

Q. How can the effect of an intensive public health attack on gonorrhea be evaluated?

A. Greenberg and Mattison (21) have emphasized the importance of program evaluation and give examples of intermediate and ultimate objectives that may be used. The attack rates of urethritis in the male and of pelvic inflammatory disease in the female appear to be our best measuring rods.

Table 1. *Gonorrhea cultures in women*

Source of culture and author	Year	Type of patient	Number of women	Percent positive
Cervix:				
Davidson and Shepard (32)-----	1948	Named sex contacts of males with gonorrhea----	42	34

¹ 25 cultures. ² 16 cultures. ³ Pelvic inflammatory disease.

Q. Has the attack rate of urethritis in the male and pelvic inflammatory disease in the female been reduced?

A. No evidence has been found for a drop in PID, but Lee (22) has shown a decrease in urethritis in the male in a rural area adjacent to a military installation during an intensive cam-

Table 2. *Effect of vigorous campaign against gonorrhea in an area near a large Army camp*¹

Date	Morbidity (in males)	
	Civilian (number of cases)	Military (rate per 1,000)
January-June 1951 ² -----	444	270

² 6 months prior to campaign.

³ First 6 months of campaign.

⁴ Second 6 months of campaign.

paign (table 2). Pereyra and his co-workers (3) have carried out a most interesting study in Atlanta, Ga. During an intensive 1½-year campaign, the number of nonwhite male patients applying to the health department clinic with gonorrhea has remained approximately constant. However, 15 Negro physicians practicing in the area stated on interview that they had experienced a 77-percent decrease in gonorrhea in males in their offices from 1952 through 1954. In addition, many clinic patients interviewed in 1955 stated that they had previously received treatment for gonorrhea from a private physician. The authors conclude that a shift of patients from private to clinic care conceals an actual decrease in gonorrhea incidence.

Q. What percentage of men sexually exposed to women with infectious gonorrhea acquire infection?

A. Certainly not all of them (personal communication from E. W. Thomas).

Q. Why do some escape?

A. May it be related to the length of the

urethra distal to the fossa navicularis? (Personal communication from P. Pelouze.)

Q. Is nongonococcal urethritis a venereal disease?

A. This condition is probably not a single entity, but in different patients may be due to mechanical, chemical, toxic, infectious, or psychosomatic factors, individually or in combination. Certain types may be transmitted by sexual intercourse.

Q. Does the gonococcus transmute into pleuropneumonia-like organisms (PPLO) under adverse conditions, and thereby become penicillin resistant?

A. Pleuropneumonia-like organisms cause certain animal diseases (bovine pleuropneumonia, agalactia in sheep and goats, polyarthritis in rats) and are found in normal humans in the female genital tract, throat, and saliva.

These organisms are resistant to all antibiotics except streptomycin.

They have been grown from cultures of eight different bacteria (including the gonococcus) when penicillin is added to solid culture media.

On transfer to fluid media, PPLO from *Streptobacillus moniliformis*, *Proteus*, and *Bacteroides* revert to original form; from other organisms, PPLO fails to grow. (PPLO isolated from animals and humans grow well in fluid media.)

Two theories may explain these phenomena: (a) symbiotic or accidental association of PPLO with bacteria; (b) growth phase—bacteria change to PPLO form under adverse conditions and thereby become penicillin resistant (23-27).

Q. Why is so little research in gonorrhea being carried out in this country? A search of the recent literature reveals significantly more investigative work on gonorrhea in the Scandinavian countries, Germany, Russia, and Great Britain than in the United States.

A. Reasons for this lack of research in the United States are not known.

How may we in the future learn the answers to some of these questions?

1. Better diagnostic tools might be developed, such as more sensitive cultural methods. Cohn and Grunstein (28) and Schauffer (personal communication) consider gonococcus culture an

insensitive method, in that many organisms must be inoculated in order to get growth. Another tool would be sensitive and specific serologic, skin, or other tests.

2. Repeated examination of women in a protected environment, following natural or purposeful infection, in order to observe the natural course of the disease and response to treatment. Such studies have been carried out in syphilis (29) and in gonorrhea in the male (30), and are equally permissible, feasible, and potentially valuable in gonorrhea in the female.

3. Repeated urethral and cervical cultures from women scheduled for hysterectomy. After operation, cultures from the excised cervix utilizing the following methods and materials: micropipette aspiration of cervical glands under the dissecting microscope, scraping of multiple cut surfaces, groundup pieces of tissue, and pus and exudate. Sensitivity of cultures would be greatly enhanced under these conditions.

4. After baseline studies of untreated women, similar studies on women treated with penicillin should help to answer the question whether penicillin cures gonorrhea in the female.

5. Similar studies in women with pelvic inflammatory disease scheduled for laparotomy. In the era of surgical treatment for PID, bacteriological studies at operation provided interesting data. Curtis (31) in 1921 reported on bacteriological study of fallopian tubes from 192 patients. The gonococcus was found in 30 percent of tubes showing gross evidence of active inflammation but was found in no case in which the tubes were grossly negative, even when there was histological evidence of active inflammation. Curtis stated that it is only rarely possible to obtain viable gonococci from patients who have been free from fever and leucocytosis for more than 10 days to 2 weeks. He concluded that the gonococcus lives only a short time in the tube, and that persistently or recurrently active gonorrheal salpingitis is due either to recurrence of infection from without (reinfection) or to repeated invasion of bacteria from the chronically infected lower genital tract. Such studies should be repeated using the most sensitive present-day cultural methods.

Conclusions

1. The true incidence of gonorrhea in the United States is unknown.
2. Widespread use of antibiotics and intensive control measures have reduced the attack rate of syphilis 93 percent in the past 8 years. It is unlikely that gonorrhea has declined to a similar extent.
3. The reasons for this difference in response to treatment are not known.
4. Interest in research in gonorrhea is at an all time low in this country.
5. To gain the knowledge needed to press the battle against the gonococcus, there must be a reawakening of interest in gonorrhea among research workers, as well as among those who provide the funds.

CDC Laboratory Refresher Training Courses

The Communicable Disease Center of the Public Health Service will give its annual laboratory refresher training courses in Chamblee, Ga., July 1956 through June 1957, according to the following schedule:

Laboratory methods in the diagnosis of bacterial diseases:

Part 1. General bacteriology. September 10-21.

Part 2. General bacteriology. September 24-October 5.

Enteric bacteriology. October 8-19.

Laboratory methods in the diagnosis of parasitic diseases:

Part 1. Intestinal parasites. September 10-October 5.

Part 2. Blood parasites. October 8-26.

Laboratory methods in the diagnosis of viral and rickettsial diseases. October 15-26.

Laboratory methods in the diagnosis of rabies. October 29-November 2.

Laboratory methods in medical mycology:

Part 1. Cutaneous pathogenic fungi. January 7-18.

Part 2. Subcutaneous and systemic fungi. (Completion of part 1 or the equivalent education or experience is a prerequisite.) January 21-February 1.

Laboratory methods in the diagnosis of tuberculosis. January 21-February 1.

Laboratory methods in the study of pulmonary mycoses. February 4-15.

Laboratory diagnostic methods in veterinary mycology. February 25-March 1.

Laboratory methods in the diagnosis of viral and rickettsial diseases. March 11-22.

Serologic methods in the diagnosis of parasitic and mycotic infections. March 11-22.

Laboratory methods in the diagnosis of rabies. March 25-29.

By special arrangement the following courses will be offered:

Laboratory methods in the diagnosis of malaria.

Virus isolation and identification techniques.

Typing of *Corynebacterium diphtheriae*.

Special problems in enteric bacteriology.

Phage typing of *Salmonella typhosa*.

Laboratory methods in diagnosis of leptospirosis.

Serologic differentiation of streptococci.

Variation in Mortality From Heart Disease

—Race, Sex, and Socioeconomic Status—

By ABRAHAM M. LILIENTELD, M.D., M.P.H.

ONE of the more important reasons for obtaining knowledge of the distribution of a disease in a population is that such knowledge provides a means by which hypotheses concerning pathogenesis can be evaluated. If a hypothesis does not adequately account for at least a majority of the epidemiological features of a disease, it will have to be modified in whole or in part.

The distribution of coronary disease in various socioeconomic groups of the population is particularly pertinent to several etiological hypotheses that have been advanced. From official studies of occupational mortality, Logan has reported the relative mortality risks from coronary disease in England and Wales for five social classes (1-3). He has observed that among men the highest social class has consistently had (both in 1930-32 and 1950) the highest mortality from coronary disease and that the mortality risk decreases with a decrease

in social status. For married women the social class variation has not been as large nor as consistent. In 1930-32 the pattern for married women was similar to that observed among men, but in 1950 little variation by social class was noted in those aged 20-64. For married women 65 years of age and over the social class pattern of proportionate mortality ratios was similar to that observed among men, although it must be realized that proportionate mortality ratios are difficult to interpret. These distributions may be considered as being consistent with the hypothesis proposed by Keys that excessive fat consumption is an important etiological factor in coronary disease (4). It is also consistent with the observation made by Morris and his associates that physical inactivity increases the risk of coronary disease (5).

Logan has also reported the results of an analysis of mortality from other forms of myocardial degeneration in England and Wales (1-3). The social class distribution for this category is exactly opposite to that observed for mortality from coronary disease; that is, the mortality risk is highest in the lowest social class and it decreases with an increase in social status. This observation suggests that the social class differences with regard to coronary disease mortality might be the result of variation in diagnostic practices in the various social classes. It is conceivable that the greater availability of medical care may have increased the number of diagnoses of coronary disease in the upper income groups.

Dr. Lilienfeld is chief of the department of statistics and epidemiology, Roswell Park Memorial Institute, Buffalo, N. Y., and associate professor of preventive medicine and public health, University of Buffalo Medical School. He began the study reported here while he was assistant professor of epidemiology, Johns Hopkins University School of Hygiene and Public Health. Dr. Matthew Tayback, chief of the statistical section, Baltimore City Health Department provided the necessary records for the study.

In view of the difficulties of diagnosis for the various forms of heart disease, it occurred to me that a combination of the deaths from coronary disease and other myocardial degeneration might be about the same for all social groups. In an attempt to study this particular question, I have made an analysis of the mortality from heart disease in Baltimore, Md., for the 3-year period 1949 through 1951. This report presents the results of that analysis. In addition to data on coronary disease and myocardial degeneration, data on hypertension and other forms of heart disease are included.

Method of Study

During the period 1949 through 1951, 14,504 deaths certified as due to heart disease were recorded in Baltimore. Of these, 3,016, or about 21 percent, occurred in the nonwhite population. The distribution of deaths for five categories of heart disease by race and sex are presented in table 1.

To estimate the socioeconomic status for each heart disease death, information concerning characteristics of census tracts in Baltimore published by the United States Bureau of the Census was used. The census tract comprises a neighborhood of between 3,000 and 6,000 persons who are relatively homogenous with regard to such characteristics as median monthly rental, occupational status, and extent of home ownership.

The census tracts in Baltimore were ranked according to the median monthly rental as determined in the 1950 census and then assembled into fifths so that about 20 percent of the city's

population of about 950,000 fell into each fifth. The median monthly rental was considered a valid index of relative socioeconomic status because of its high correlation with the other indexes, such as family income, years of school completed, and occupation. The lowest socioeconomic fifth was designated 1; the next fifth, 2; and so on. Each heart disease death was assigned to a socioeconomic fifth on the basis of its allocation to a given census tract from the street address on the death certificate.

One possible limitation to this method of socioeconomic classification, particularly with regard to nonwhite persons, should be noted. Because the method is based on average characteristics of an area rather than actual characteristics of an individual, nonwhites, for example, may be classified in a socioeconomic group higher than their socioeconomic circumstances warrant when they are located in a census tract that is predominantly white. The same difficulty is present with regard to the white population but probably to a lesser extent. However, census-tract classification provides an inexpensive and readily available method for studying the socioeconomic distribution of mortality from a disease.

For comparison with the Baltimore data, some of the data for England and Wales reported by Logan will be presented. In the British reports on social distribution, classification is based on occupational groups. According to the 1951 census, 3.3 percent of the male population aged 15 years and over falls into social class I (professional); 15.0 percent in class II (intermediate between I and III); 52.7 percent in class III (skilled); 16.2 percent in class

Total-----	6, 155	5, 336	1, 546	1, 467	14, 504

¹ Numbers in parentheses are category numbers of the International Statistical Classification of Diseases, Injuries, and Causes of Death, sixth revision of the International Lists, 1948.

IV (semiskilled); and 12.8 percent in class V (unskilled) (2, 3). Thus, the English social classes I and II are roughly comparable to the Baltimore socioeconomic fifth 5; social class III, to socioeconomic fifths 3 and 4; social class IV, to socioeconomic fifth 2; and social class V, to socioeconomic fifth 1. By presenting this information, I do not intend to imply that the two classifications are completely comparable; it merely gives some idea of their comparability with regard to the percentage of population in each class.

In making comparisons between sexes, races, and socioeconomic groups, differences in the age composition of the population in these groups must be taken into account. This can be done readily by the method of age adjustment commonly employed in routine vital statistics practice. For this study, the standard population used for age adjustment was the total population of Baltimore in 1950. The data presented for each sex, racial, and socioeconomic group are average annual age-adjusted death rates and are therefore directly comparable.

In the British reports, an indirect method of age adjustment resulting in an index termed the standardized mortality ratio was used. Since this method differs from the one used to describe the Baltimore experience, the results cannot be directly compared in absolute terms. However, comparisons can be made between the social classes within each of the two geographic areas, and it is with such comparisons that we are concerned. The interested reader is referred to the text on medical statistics by Bradford Hill, where these methods of age adjustment are discussed (6).

Arteriosclerotic Heart Disease

The International List category designated arteriosclerotic heart disease includes three subcategories: arteriosclerotic heart disease, coronary artery disease, and angina pectoris. All heart disease deaths in which coronary artery disease is mentioned are placed in this category, but, admittedly, deaths not due to coronary disease are also included. This category was used as representing deaths from coronary disease in the analysis of mortality in England and Wales in 1949 and 1950. It would appear

Table 2. Average annual age-adjusted death rates per 10,000 population for arteriosclerotic heart disease (including coronary disease)¹ by race, sex, and socioeconomic status, Baltimore, 1949-51

reasonable to assume that if there are significant racial, sex, or socioeconomic variations in mortality from coronary disease, it would be possible to detect them by an analysis of this category of deaths, unless, of course, the distributions of each subcategory are in opposite directions.

The results of the analysis of mortality from arteriosclerotic heart disease in Baltimore are presented in table 2. It is to be noted that males have markedly higher death rates than females, in both racial groups and in all socioeconomic groups. But perhaps of more interest is the fact that there is no particular pattern of variation in mortality for the different socioeconomic groups; the differences between socioeconomic groups may well be due to chance variation.

The lack of a socioeconomic pattern in Baltimore is in marked contrast to the findings

social class distribution in England and Wales in 1950, which are shown in table 3. In England and Wales, there is an increasing gradient of mortality ratios from the lowest class to the highest among men, and there is a slightly increasing gradient in the reverse direction among married women. Admittedly, the Baltimore and the English data are not strictly comparable. The methods of classifying socioeconomic status differ, and the English data are limited to age groups 20-64 years. (The data for persons aged 65 and over are not presented here because they are expressed as proportionate mortality ratios.) Also, there are differences in the reporting and classification of causes of death: For example, in England the term "arteriosclerotic heart disease" is infrequently used in reporting causes of death. Nonetheless, it seems reasonable to expect that if social class variations in mortality from coronary disease did exist in Baltimore as

they appear to exist in England, they should have been evident in the data presented in this report.

Myocardial Degeneration

The age-adjusted rates for deaths from other myocardial degeneration in Baltimore are presented in table 4. This category, according to the International List, includes such terms as fatty degeneration, myocardial degeneration with arteriosclerosis, cardiovascular degeneration, atheroma of heart or myocardium, and chronic myocarditis.

In general, the rates for white males are higher than the rates for white females, but there is little difference between the sexes for the nonwhite population. In addition, the white and nonwhite male rates are nearly the same. Thus, the nonwhite rates for both sexes are similar to the white male rates, and the white female rates are lower than the rates for the other three groups. This general pattern, which is present for all the socioeconomic groups, differs from that observed for deaths due to arteriosclerotic heart disease. The socio-

economic distribution also differs from that for arteriosclerotic heart disease. There is a decreasing gradient of mortality from the lowest socioeconomic group to the highest, for both races and both sexes.

The social distribution of mortality from myocardial degeneration in England and Wales in 1950 is shown in table 5. For this category of heart disease, the pattern is similar to that for Baltimore. This similarity perhaps increases the significance of the lack of consistency between the two areas with regard to coronary heart disease deaths. It would not seem that differences in the method of classification of social classes or the limitation to a certain age group would produce differences in the patterns of one group of deaths and not in the patterns of another.

Hypertensive Disease

Classified in the International List under hypertensive disease are eight categories. For this report, these have been grouped into (a)

hypertension with mention of heart disease and (b) hypertension without mention of heart disease. The rates for these two groups are presented in table 6. Since there are only a few deaths classified in the second group, no conclusions can be drawn from the data.

For hypertensive disease with mention of heart disease, the rates for the nonwhites are about twice as high as the rates for the whites. This is true for both sexes and for all socioeconomic groups. The rates for the females are higher than the rates for the males in both racial groups. The higher white female rates are present in all socioeconomic groups except the highest group, where the male rate exceeds the female rate. Among the nonwhites, the female rate is higher than the male rate in the three lower socioeconomic groups, but a suggested reversal occurs in the two upper socioeconomic groups. This change in mortality relative to sex and social class, which occurs in both races, may be of some epidemiological interest and worthy of further investigation.

It seems that the lower socioeconomic groups have a higher mortality from hypertensive disease (with mention of heart disease) than the upper groups, and, among females of both races, there is a suggestion of a decreasing gradient from the lowest socioeconomic group to the highest. This pattern can be considered as suggestive only, particularly since it is not clearcut for the males of either race.

Other Results

In view of the differences between the Baltimore and the English experiences with regard to coronary disease deaths, I thought that perhaps the method of age adjustment might be concealing existing differences between social classes. For a better comparison of the mortality in the various social groups, age-specific death rates for three categories of heart disease are presented in tables 7 through 9. Examination of these rates confirms the existence of the patterns noted in the analysis of the age-adjusted rates.

The deaths classified in the remaining heart disease categories in the International List were grouped together, and the age-adjusted rates are presented in table 10. Owing to the heterogeneity of this group, no inferences can be drawn. Unfortunately, no one form of heart disease in this group could be singled out for further study because of the small number of deaths.

Discussion

Before discussing the inferences that can be derived from the results of this analysis, attention should be directed to some of the limitations of the data. Of prime importance is the question of the accuracy of cause-of-death statements on death certificates. Recently, James, Patton, and Heslin reported an "appreciable degree" of inaccuracy when the causes of death on death certificates were compared with autopsy findings (?). The possibility of inaccuracy in cause-of-death statements imposes a serious limitation on what can be inferred from

the analysis of mortality data. But analysis of death certificate information is a readily available, inexpensive means of studying distributions of certain diseases, and it is generally considered a satisfactory method of uncovering areas for further investigation. Another limitation, as already pointed out, results from the use of census tracts as a means of socioeconomic classification.

The initial interest in this analysis was to determine whether the social pattern of coronary disease mortality observed in England and Wales might be due to differences in diagnostic practices in the various social classes. It seemed that this might be inferred if a similar pattern were observed in Baltimore and if a combination of the deaths from coronary disease and other myocardial degeneration should result in a disappearance of the social differential. But the distribution of coronary disease deaths was not found to be like the English pattern. If the two categories were combined, the highest socioeconomic fifth would

have the lowest rates, and there would be an increase in the mortality risk with a decrease in socioeconomic status. On the other hand, a reviewer of this paper has shown that when the English data for these two categories are combined, the highest social class still has the highest rates, although the difference between social classes is diminished.

To explain the discrepancies between the Baltimore and English experiences, one is tempted to postulate the existence of possible biological differences. For example, from the viewpoint of a dietary hypothesis of coronary heart disease, it is conceivable that there may be differences in dietary habits among the social classes in England that do not exist in Baltimore. But before hypothesizing this type of explanation, it would be necessary to eliminate the possible influence of nonbiological differences, such as methods of social classification and of death certification and diagnostic practices.

The present analysis also raises the question as to whether the pattern observed in England and Wales can be used as a test of the consistency of any particular etiological hypothesis of coronary disease with the social distribution of mortality from this disease. If the social distributions were found to be similar in many geographic areas, the confidence with which these distributions could be used as an index of the validity of an etiological hypothesis would be increased. The apparent existence of dissimilar distributions in Baltimore and in England and Wales suggests the need for further investigation of social variations in heart disease mortality.

Summary

From information on certified deaths in Baltimore during the period 1949 through 1951, mortality from various types of heart disease was analyzed by race, sex, and socioeconomic status.

Mortality rates for arteriosclerotic heart disease (including coronary artery disease) were observed to be higher among males than among females and higher in the white population than in the nonwhite. No significant differences were noted in the rates for five socioeconomic groups. This latter observation is in contrast to the social distribution found in England and Wales, where the risk of dying from coronary disease is highest in the upper social classes.

Mortality rates for myocardial degeneration were higher among white males than among

white females. Among the nonwhites, no essential differences were noted between the sexes. The rates for the nonwhites were somewhat higher than those for the whites. For both sexes and both races, the highest rates were noted in the lowest socioeconomic group, with a gradual decrease in rates with an increase in socioeconomic status. This social distribution is similar to that observed in England and Wales.

Mortality rates for hypertensive disease were higher in the nonwhite population than in the white. The lowest socioeconomic group had the highest rates, and there tended to be a decrease in rates with an increase in socioeconomic status, although the pattern was not regular. The female rates were higher than the male rates in the lower socioeconomic groups, whereas the reverse was true in the upper groups; this was observed for both races.

The use of death certificate information for analysis of mortality and the use of census tracts for socioeconomic classification both impose certain limitations on the data derived. Nonetheless, the apparent existence of differences in the social distribution of coronary disease deaths in two geographic areas indicates a need for further study of the subject.

The epidemiology of the septic tank is described with suggestions for helping builders of mass housing to prevent future disease outbreaks and nuisances.

Sewage Disposal in Mass Building

By DAVID B. LEE, M.S. in Eng.

IN the past 10 years, the urban fringe has seen the installation of millions of septic tanks, far more than had been eliminated by sanitary engineering services in the previous 50 years.

The septic tank has been installed not only for those who have land and income generous enough to accommodate and maintain the facility, but for families who have neither the space nor the resources to prevent the development of a sanitary nuisance and a public health hazard. Often such families must go to the expense of a new installation or, if possible, thorough reconstruction. Septic tanks may work well in rural areas if people do not live too close to each other or use a great deal of water for bathing, laundry, air conditioning, and dishwashing.

To put it simply, a septic tank is a country cousin that came to town and promptly got into trouble. In its place—a rural setting—the septic tank and subsurface drain field is a suitable method of domestic sewage disposal, given adequate drainage, soil conditions, and water table; but it was never intended for use in settlements with more than one family dwelling per acre. Even this may be too dense for septic tanks if soil conditions and water tables are not ideal.

Where public facilities cannot be arranged,

the septic tank soil absorption system of sewage disposal, originally designed for rural areas, is now widely utilized as a convenient and temporary substitute. Under rural conditions and with proper design, construction, and maintenance, this system will usually give some degree of satisfactory performance.

If failure of the soil absorption system occurs under rural conditions, the danger to public health is minimum since there are plentiful opportunities to choose another location for a new system. In urban areas, the septic tank is often a needless and frequently an extravagant method of sewage disposal which threatens to be a sanitary nuisance and a public health hazard to millions of homeowners.

Then, why have there been so many septic tanks installed during the past 10 years?

The following discussion will attempt to explain why builders adopt these expedient but short-sighted construction methods and to suggest what may be done about it.

The epidemiology of the septic tank itself suggests therapeutic and preventive measures for this form of community sickness, a sickness that is appraised not only by the number of individual infections but by nuisance, expense, and disorder. It is the business of public health to treat the community as the physician treats the person. And in view of the prospect of the continuing building boom, it is the business of public health to assure that this community sickness will not prevent or stunt healthy community growth.

Mr. Lee is director of the bureau of sanitary engineering, Florida State Board of Health, Jacksonville, Fla.

Builders Are Human

In my judgment, the postwar building program is yet to reach its peak in many areas of the country. The housing deficit, accumulated since 1926, has been overcome only in isolated communities and for isolated income groups. Much of the housing built since 1940 has been only a temporary palliative to housing needs. Millions of units, fundamentally well-built and well-equipped, are already too small for growing families. With rising incomes, families are demanding more of housing. If you add to these factors the steady obsolescence of aging buildings, spatial shifts of population, and the rising birth rate, it is apparent that the current production rate of 1.3 million dwelling units a year is not excessive.

Accurate figures are not available, but in my opinion the estimate that at least 24 million persons in the United States are served by 6 million individual septic tank systems is close to the truth. More important, however, is the estimate that more than one-third of the new homes now being constructed will have septic tank systems for sewage disposal. All of this continues against the better judgment of many in the public health profession, and presents one of the greatest challenges sanitary engineers and other public health workers will have to face in the years to come. Must we abet septic tanks?

The mass building industry is chronically in need of land, low-priced land, in large tracts. Such land is seldom to be found within city limits, where zoning laws and city plans apply, and where community water and sewerage facilities are likely to be present or required.

Mass builders usually find the land they need in territory where inhabitants or governing authorities have had meager or limited experience in urban development. It is unlikely that in such an area there is any local person equipped to supervise the builders and their sewage disposal plans. The burden of supervision usually falls on the county and State officials and, in some instances, on the insuring and lending agencies. Even so, in the interest of profit and sound construction, progressive mass builders would prefer to put in community water and

Serving several subdivisions, this activated sludge plant houses two primary mechanical aerator units, a sludge digester, laboratory, pump room, office, and truck loading room for digested sludge. The slump brick terrace (lower terrace) is a chlorine contact chamber and the higher terrace (second floor level) is a secondary clarifier.

sewerage facilities. What stands between them and their better judgment is a matter of money.

Typically, a builder does not construct 200 houses wholesale and then sell them in one lot. In phase building, he finishes one house at a time. And he sells one at a time, as the units are finished. Even if his sales are committed in advance, settlement of the title is closed only as the individual houses are finished.

Naturally, he wishes to recover water and sewerage installation costs on each house as it is sold. Such recovery is easiest when the house has a private well and septic tank.

It is not as easy to recapture the investment in community facilities with any rapidity. To provide community sewerage facilities for no more than 500 units would tie up between \$150,000 and \$200,000 while the houses are in construction. It may take a little time before this investment can be freed. There have been few, if any, financial institutions willing to carry that kind of investment, especially for builders who may sell no more than 50 to 100 houses a year. Such financing is certainly not practical for the typical builder who needs a fast turnover on limited capital simply to keep himself going. Even mass builders are susceptible to the appeal of the fast return of their

money. Some have ventured to use septic tanks with projects of as many as 8,000 homes and larger.

The Cost of Services

Given financing, it would be to the great advantage of both the builder and the community to install community water and sewerage facilities. To deal with sewage disposal alone, the Florida builder can install sewers at a charge ranging from \$150 to \$250 per lot. To include the cost of sewage treatment facilities for 500 families in my own State would run the total charge for sewage disposal facilities to from \$300 to \$400 a dwelling.

The superior attraction of a house with sewerage connections will enhance the market value of the structure by some amount over and above the ordinary charge for septic tank installations. Although the increased value of the house may return a price that will pay for the community sewage collection and treatment facilities, title to the plant would remain with the builder. Furthermore, by collecting sewage service charges, he may cover operating, maintenance, and amortization costs, and so recover his investment. Meanwhile, the community would have the advantage of a trouble-free waste disposal system. The gross income from 500 houses with community water supply and

Carol City activated sludge plant as seen from across the manmade lake into which the effluent discharges.

community sewerage may amount to approximately \$30,000 a year. Such an operation is practical with as few as 200 houses.

Recognizing such financial advantages, 120 subdivisions in Florida have installed their own community sewage disposal facilities and community water systems in the past 5 years. But several were motivated also by a stern refusal by government officials to permit septic tank construction in areas where such disposal methods are no longer suitable.

It can often be demonstrated that the average cost of a septic tank and subsurface disposal system and the cost of maintaining and operating such a system are certainly equal to, and, in many cases, more expensive than a monthly sewer service charge for a method of sewage disposal that is not only safe but trouble free.

Corrective Measures

Once septic tanks are in, especially in areas with a high water table, poor soil conditions, and relatively dense settlement, the corrective measures frequently require that they be bypassed. They may serve well during dry periods but let the rains come and in no time the soil is saturated: From the ground surface noxious gases will come forth; septic tank effluents will appear on the ground; they may

back up into bath tubs or prevent the flushing of commodes.

As this was written, on January 24, 1956, two ladies called me to report that more than 100 septic tanks in their subdivision had failed in the past 24 hours. The gases coming back through the plumbing and into the house were so serious that the house had to be opened and the attic fan used to freshen the air. This was besides the fact that the yard was flooded with septic tank effluent.

In one subdivision with 180 homes of a high financial bracket, soil conditions were such during 1955 that 25 homeowners were obliged to construct relief sewers from their drain field to the roadside ditch in order to allow the wastes to escape.

Since sewerage is the only practical correction for defective septic tank installation, it seems obvious that in mass building projects sewers should be installed when the homes are built.

We, in Florida, recommend that plumbing in all new houses be so constructed and septic tanks, when used, be so located—on the side of the house or in the front—as to facilitate eventual connection to a sanitary sewer.

Preventive Measures

What can be done to assure that mass housing projects of the future will be built with adequate community sewerage facilities?

Of all possible means of preventing undesirable septic tank construction in the future, aggressive, direct efforts by government officials, by builders, and by insuring and financing agencies are most likely to produce results. Governments and political subdivisions can strive to overcome artificial political barriers which today strangle rational urban growth, and which, in fact, encourage undesirable building in outlying areas at the expense of well-established urban centers. Whether it is done by creating sanitary districts, metropolitan or regional planning authorities, county and State zoning officials, new boundaries, or local government holding companies, the accommodation of urban growth is a primary political responsibility of local and State governments.

If local and State governments impart such

political muscle to zoning and planning commissions, it cannot be too heavily stressed that members of such commissions should be independent of financial pressure and political and special interests. Commissions should be staffed by qualified and intelligent laymen as well as professional personnel with merit system status. They should also be sensitive to the welfare of the people and be interested only in the development of the area they serve and the part it plays in the development of the State and the Nation.

The most immediate opportunity for good work in urban growth, however, is in the hands of agencies which insure, guarantee, or underwrite funds for residential construction and development. It would be to their own interest and protection to assure loans for community water and sewerage facilities and to require such systems for all dwellers whose financing they insure in mass building developments. If these agencies would do no more than agree to insure mortgages on community facilities, builders, the financial people, sanitary engineers, and others will certainly work out the details. In my opinion, the greatest need in housing today is for leadership in the financing of community water and sewerage facilities.

Summing Up

Based on my experience, it has been demonstrated that the septic tank in congested neighborhoods is uneconomic, unwise, and unwholesome. Its widespread use in recent years may be due largely to the failure of local government officials to assure wise and orderly development of new neighborhoods and to the failure of financial institutions to encourage builders to install community sewerage facilities. Since sewerage facilities are the only practical alternative to the use of septic tanks, their construction must be encouraged if we are to avert the installation of millions of septic tanks in the next 10 years. All government agencies need to organize better methods of managing urban and suburban growth. But immediate benefits will result from agreements by insuring and lending agencies to finance community facilities for water supply and sewage collection and treatment.

50 years — of Food and Drug Protection

By **GEORGE P. LARRICK**

Commissioner of Food and Drugs

This section of *Public Health Reports* is devoted to an account of some of the principal programs of the Food and Drug Administration which affect public health.

It is an appropriate way to commemorate the golden anniversary of our first Federal pure food and drug law, not so much by reviewing the past as by considering the challenge of the future.

The articles are by men directly concerned with the administration of the programs. It is notable that they consistently emphasize technological changes in foods, drugs, and cosmetics, affecting an important part of the human environment.

From the beginning the food and drug law has been directed at specific abuses: errors of omission or commission which can be proved in a court of law. Likewise, the law has from its beginning reflected the standard of achievement attained by the majority of producers of foods and drugs and has required the backward element to meet that same standard.

As a result, food and drug law enforcement has been a stimulus to industrial progress as well as a direct and practical means for dealing with important environmental health hazards.

The original Pure Food and Drugs Act which Theodore Roosevelt signed into law on June 30, 1906, was one of the great milestones of public health progress. Few, if any, events have had a greater effect in promoting such objectives as the sanitary handling of food or rational therapeutics in medicine. It would be fitting to dedicate these papers to Dr. Harvey W. Wiley, who, more than any other, was responsible for the enactment of this law.

Each generation needs to learn anew the why and wherefore of its institutions and blessings; otherwise they are taken for granted. Today, the right of the public to pure foods, effective drugs, safe cosmetics, and truthful labels has become generally accepted. It was not always so. We need to be reminded of Dr. Wiley and his 23-year struggle to obtain our first Federal pure food and drug law. It helps us understand and appreciate the value of the protective laws we now have, and the truly wonderful progress made by our food, drug, and cosmetic industries in this half century. It also helps us understand our problems of today and our obligation to insure that food and drug products of today and tomorrow will continue to be the best in the world.

Significant Dates in Food and Drug Law History

Since the beginning of recorded history, men who have organized themselves into civilized societies have been concerned about the purity of the food and drink offered to the public.

In 1202, King John of England proclaimed the first English food law, the Assize of Bread. This prohibited adulteration of bread with such ingredients as ground peas or beans.

The history of food and drug measures as it has developed in the United States is set forth in the following chronology:

1784. Enactment by Massachusetts of the first general food law in the United States.

1824. Flour Inspection Act for Alexandria, then in the District of Columbia.

1844. Dr. Harvey Washington Wiley was born October 18 at Kent, Ind.

1848. Edwards law passed to prohibit the importation of adulterated drugs.

1850. A pure food and drink law was passed in California, one year after the gold rush.

1879-1906. During these 27 years more than 100 food and drug acts were introduced in Congress.

1879. Chief Chemist Peter Collier, Division of Chemistry, Department of Agriculture, began a food and drug adulteration investigation.

1880. Peter Collier recommended enactment of a national food and drug law.

1883. Dr. Wiley became chief chemist of the Division of Chemistry of the Department of Agriculture on April 9. Immediately he assigned some members of his staff to study the problems of food and drug adulteration.

1883. The Tea Importation Act was passed, providing for inspection of all tea entering United States ports.

1890. Acts were passed prohibiting importation of adulterated food and drugs and providing for certification of certain exported meat products.

1891-1895. Partial protection of domestic consumers was effected by acts requiring inspection of animals for diseases before slaughtering.

1902. Sherman Act, passed by Congress on July 1, prohibited the false branding of food and dairy products. In this same year appropriations were made by Congress to establish pure food standards.

1906. The first Federal Food and Drugs Act (34 stat. 768), the Heyburn Act, passed Congress and was signed June 30 by President Theodore Roosevelt. The President also signed the Meat Inspection Act on that day.

1907, January 1. The Bureau of Chemistry of the Department of Agriculture, headed by Dr. Wiley, began administration of the Food and Drugs Act of 1906.

1912, March-December. Dr. Wiley was succeeded by Dr. Carl L. Alsberg as chief chemist of the Department of Agriculture. Regulatory and research functions were separated.

1913, March 3. Gould amendment (37 stat. 732), requiring that quantity information on food packages be correct, passed.

1919, July 24. Kenyon amendment (41 stat. 271) passed. It applied net-weight labeling to wrapped meats.

1921, July. Dr. Alsberg was succeeded by Walter G. Campbell, who became acting chief of the Bureau of Chemistry.

1924, July. Mr. Campbell took over all regulatory work of the Bureau of Chemistry as a separate function, as Dr. Charles A. Browne became chief of the Bureau.

1927. A separate law-enforcement agency was formed, first known as the Food, Drug, and Insecticide Administration; then, in 1931, as the Food and Drug Administration. Mr. Campbell became Commissioner of Food and Drugs.

1930. The canning industry supported the McNary-Mapes amendment, authorizing standards of quality and fill of container for canned foods.

1938. The Copeland bill was passed by Congress. It was known as the Food, Drug, and Cosmetic Act of 1938, and contained these new provisions, among others:

Extended coverage to cosmetics and devices.

Required predistribution clearance of safety on new drugs.

Prohibited addition of poisonous or deleterious substances to foods, except where required or unavoidable.

Provided for tolerances for unavoidable or required poisonous substances.

Authorized standards of identity, quality, and fill of container for foods.

Authorized factory inspections.

Added the remedy of court injunction to previous remedies of seizure and prosecution.

1940, July 1. FDA transferred from the Department of Agriculture to the Federal Security Agency.

1944, May 1. Dr. Paul B. Dunbar succeeded Mr. Campbell as Commissioner of Food and Drugs.

1945, July 6. Federal act amended to require certification of the safety and efficacy of penicillin. Later amendments extended this requirement to other antibiotics.

1948, June 24. Miller amendment (62 stat. 582) affirmed United States jurisdiction over products adulterated or misbranded after interstate shipment.

1951, June 1. Charles W. Crawford succeeded Dr. Dunbar as Commissioner.

1951, October 26. Durham-Humphrey amendment (65 stat. 648) specifically required that drugs which cannot be safely used without medical supervision bear the pre-

scription legend on the label and be dispensed only upon prescription.

1953, August 7. Factory inspection amendment (67 stat. 476) clarified previous provision regarding mandatory factory inspection, and required the issuing to manufacturers of written reports on inspections and analysis of factory samples.

1954, April 15. Hale amendment (68 stat. 54) simplified method of promulgating food standards where no controversy was involved.

1954, August 12. George P. Larrick succeeded Mr. Crawford, who retired as Commissioner.

1955. Secretary Oveta Culp Hobby of the Department of Health, Education, and Welfare appointed a committee of 14 distinguished citizens to study the adequacy of the Food and Drug Administration's facilities and programs.

1955. The Citizens Advisory Committee reported on June 30, recommending a substantial expansion of FDA's facilities, a new building for FDA, and more use of educational and informational programs by FDA.

1956. The 50th anniversary year, a year of tribute and rededication on the part of government and industry to the cause of effective food and drug protection.

THE BIRTHDAY SEAL

Adopted by the Association of Food and Drug Officials

Food Sanitation

By GLENN G. SLOCUM, Ph.D.

In the first annual report of the Bureau of Chemistry, Department of Agriculture, after the passage of the Food and Drugs Act of 1906 (1), Dr. Harvey W. Wiley stated: "Any unfavorable conditions found in the factories inspected were subsequently discussed with the inspectors, with a view . . . of impressing upon them the necessity of sanitation in the preparation of articles of food and drugs . . ." Thus, food sanitation programs were initiated at the inception of enforcement of the first Federal food and drug law. They have continued for 50 years to occupy a prominent position in the work of the Food and Drug Administration.

The Food, Drug, and Cosmetic Act of 1938, like the act of 1906, is basically a statute to protect the public health. Proper sanitation in the production and handling of foods and drugs is one of its major requirements.

A sanitary food, strictly speaking, is one free from injurious substances, particularly infectious micro-organisms. But modern concepts of food control have expanded this definition to include freedom from materials that are repulsive or obnoxious regardless of their importance as agents of disease. This development is an important factor in the protection of health, since many forms of food contamination carry potential health hazards that cannot be measured, even with modern analytical tech-

niques, by objective examination of food products. The expanded definition has become generally accepted by the food industries and the public, and it is firmly established by many court decisions in actions brought under the food and drug laws.

The requirements of the law and the objectives of the Food and Drug Administration with respect to food sanitation may be stated simply: that foods be prepared from clean, sound, and wholesome raw materials and that sanitary conditions prevail at all stages of production and distribution. It has been the consistent policy of the Food and Drug Administration through 50 years of enforcement of the food and drug laws to seek to improve the sanitary quality of the food supply by all means and facilities at its disposal.

The Early Activities

When the Food and Drugs Act was enacted in 1906, interstate traffic in foods was limited primarily to a few staple products. Food production and distribution were largely local operations, and the housewife usually processed the basic raw materials in her home. Although Dr. Wiley and others supporting the drive for legislation were preoccupied with such problems as the use of harmful or potentially harmful chemicals in foods and widespread economic adulteration, writings of that period show that there was a real recognition of and concern with problems of food sanitation.

Early administrative reports of the Bureau of Chemistry, Department of Agriculture—the agency charged with enforcement of the Food

Dr. Slocum is chief of the Division of Microbiology, Food and Drug Administration.

and Drugs Act until the Food and Drug Administration was created in 1927—clearly trace the development of food sanitation programs (1). Sanitary requirements of the law were stressed in inspection of all food processing and distributing facilities. Field and laboratory investigations of sanitation were soon initiated for many important commodities, including milk, cream, ice cream, bottled mineral waters, shellfish, gelatin, poultry, and fresh, frozen, and dried eggs. Bacteriological and microscopic methods of analysis for detection of contamination and spoilage were developed and put into use. Research operations not only revealed enforcement problems and methods for the detection of contamination but also provided information to help industry avoid violations and improve the overall quality of the product. This educational approach, which has always been coordinated with enforcement of the legal requirements of the food and drug laws, is often unknown to those not fully conversant with the Food and Drug Administration's work.

One of the outstanding personalities in the early food sanitation programs was B. J. Howard, chief of the microchemical laboratory of the Bureau of Chemistry. His applications of the microscope to the detection of decomposed, filthy, or insanitary foods were a major contribution to improvement in the sanitary quality of foods in this country. For the development of a mold count method of detecting rot in tomato products, he received worldwide recognition.

Although the microbiological aspects of food sanitation were an important element of the early investigations, a separate microbiological laboratory was not created in the Bureau of Chemistry until 1913. Under the direction of Dr. Charles Thom, the noted mycologist, the laboratory continued and expanded investigations in food sanitation and spoilage and food poisoning. It was in this laboratory that Dr. Stewart Koser conducted his studies of the metabolism of coliform organisms. His findings form the basis today for distinguishing *Escherichia coli* from other members of this group. Research in food sanitation was further expanded under Dr. A. C. Hunter, who became director of the bacteriology laboratory

when the Food and Drug Administration was created in 1927. Drs. Thom and Hunter were authors of the book "Hygienic Fundamentals of Food Handling," published in 1924. It was one of the earliest books, if not the first, on this subject.

Improvements in the Law

The Food and Drugs Act of 1906 defined a food as adulterated "if it consists, in whole or in part, of a filthy, decomposed, or putrid animal or vegetable substance . . ." This was the legal basis on which the food sanitation programs were founded. Although major improvements resulted from application of this requirement, there was early recognition of serious limitations of the law. This is best summed up by the following statement from the 1933 Report of the Food and Drug Administration by Walter G. Campbell (1):

"One of the most serious limitations of the present law, of especial moment where public health questions are involved, is the lack of control of insanitary practices in food-manufacturing plants. Jurisdiction under the Federal statute exists only after a product has been shipped or offered for shipment within the scope of the law. The detection of insanitary practices through inspection in the manufacture of food products does not give sufficient warrant for removing offending goods from interstate channels. To obtain evidence of contamination that will warrant a charge of adulteration within the meaning of the law, it is necessary to collect representative samples of the product and analyze them. This is by no means always an easy matter. Analytical methods have not been developed with that degree of refinement needful to establish in all instances evidences of insanitary handling of a product originating in an insanitary factory."

This important gap in the law was corrected in the Food, Drug, and Cosmetic Act of 1938. It defines food as adulterated—

"If it consists in whole or in part of any filthy, putrid, or decomposed substance, or if it is otherwise unfit for food; or

"If it has been prepared, packed, or held under insanitary conditions whereby it may have become contaminated with filth, or

whereby it may have been rendered injurious to health. . . ."

Other requirements of the 1938 law or its amendments made factory inspection mandatory and extended jurisdiction to articles adulterated while held for sale (whether or not the sale is the first one) after shipment in interstate commerce.

These changes gave the Food and Drug Administration legal authority to deal comprehensively with food sanitation.

Enforcement Procedures

The 50 years of food law enforcement coincides with the period of vast expansion of the food industries. Increasingly, food production has moved to large factories which distribute products throughout the Nation. Often the products have been so altered in form that the consumer has little basis on which to judge their original cleanness and wholesomeness. As the more obvious forms of adulteration disappeared, newer, more subtle forms became apparent. These have required development of new techniques for their detection.

To provide for the most effective and efficient use of the limited funds and facilities available to deal with the increasing needs for consumer protection, the project system of operations was introduced in 1922. In brief, this system consisted in the formulation of a comprehensive and unified plan of operations for the entire field force, directed against specific classes of products that experience had shown to be most likely to be in violation. Priorities were assigned for work allocations in the following order:

1. Violations involving danger to health.
2. Offenses against decency (insanitation, filth, and decomposition).
3. Economic adulteration.

The project system is the basic pattern for the regulatory programs of today, including the programs in food sanitation.

In order to determine the types, sources, and routes of transmission of contamination, a knowledge of methods of production, processing, packaging, and marketing is necessary. This information is obtained through broad investigations of an industry in various locali-

ties by inspectors of the field force, usually in collaboration with technical experts from the Washington headquarters. With this background, inspectional and laboratory techniques are devised, policy is determined, and a plan of action is issued for uniform application throughout the country.

The basic operation in a food sanitation program is the sanitary inspection of the factory. The likelihood that food may be polluted or contaminated with filth in the factory is in proportion to the distance between the filth and the product under preparation. The objective of the sanitary inspection is to measure this distance in terms of space, time, opportunity for pollution or contamination, and vehicles of transmission.

An establishment operating in a manner to invite, or permit, contamination of food with foreign matter properly classified as filth is insanitary. The objectionable matter may be the excreta of man or animal, or it may be flies, maggots, worms, insects or insect parts, rodent hairs, or other such material.

In many instances, the contaminants are macroscopic, and detection of the avenues of their entrance into food depends only on keen powers of observation and common sense. In other instances, the contaminants are micro-organisms or microscopic filth, and knowledge and appreciation of invisible routes of distribution are required.

Sanitary inspection evidence alone, presented in court by the inspector, often with pictures and exhibits demonstrating insanitary conditions, is sufficient to support a charge that the product "may have become contaminated with filth." Such action is essential in instances in which the objective evidence of even gross contamination has been removed or destroyed by such processes as filtration or pasteurization of the product. More commonly, however, insanitary conditions result in contamination that can be detected in the finished product by bacteriological or microscopic examination.

In practice, then, products shipped from an insanitary establishment are usually sampled in interstate commerce for laboratory analysis. The findings may confirm the inspection evidence of insanitation and establish the presence of filth in the product. Offending products

Figure 1. Establishments engaged in distribution of products subject to regulation by the Food and Drug Administration.

may be removed from the market through seizure by the Federal courts, and the shipper may be prosecuted for, or enjoined from, violating the sanitary requirements of the law.

Voluntary Correction

Application of these techniques on an industrywide basis, within the limits of funds and facilities, exerts a strong corrective influence. Correction depends on education, and education is inherent in enforcement of the food sanitation requirements. The basic investigations essential to development of a food sanitation program are usually conducted widely in the affected industry. Methods developed to detect contamination are made available to industry for use in preventing contamination. The food and drug law now requires that the FDA inspector give to the agent in charge of the establishment a written report of conditions or practices that might lead to violations of the sanitary requirements of the law. Prior to this amendment, the inspectors discussed with management any such conditions so that voluntary corrective measures might be instituted.

The Food and Drug Administration also promotes voluntary compliance with the law by such means as talks to trade groups, surveys, consultations, and, whenever practicable, direct assistance in solving technical problems. Punitive action under the law then, falls largely on operators who are careless or who are unwilling to use the measures available to them to avoid violations.

It has been stated that the food and drug laws, and particularly the "unsanitary conditions" clause in the definition of adulterated foods, have been major stimuli to improvement in food sanitation (2). Certainly this new provision focused attention on a phase of food handling not well attended to by some industries in the past. The response to this provision by the food industries has been gratifying. There are few trade associations or large operators in the food field that are not now active in programs to improve sanitation.

Need for Expansion

Despite the progress that has been made, there is a serious need for expansion of all food

sanitation programs—national, State, and local. As shown in figure 1, there are some 96,000 establishments in this country distributing products subject to the Federal food and drug law, the vast majority of which are in the food field. In addition, food and drug imports are subject to the same requirements. There are sanitation problems of greater or lesser degree connected with all the food commodity groups listed. About 10 percent of the establishments can be inspected and about 7 percent of the imports can be sampled each year with the present staff (fig. 2).

The major food sanitation programs of the Food and Drug Administration have been concerned with certain cereal products, butter and cheese, certain fruit and vegetable products, bakery products, confectioneries, eggs, and certain fish products. Current emphasis is on edible oils and poultry. Many commodities within these groups and others in figure 1 have not received organized action with respect to sanitation.

During fiscal year 1955, an average of about 75 tons a week of insect-infested, rodent-defiled, or decomposed food was seized under the food and drug law and removed from trade chan-

nels. More than four-fifths of all food seizures fall in these categories. Though a substantial proportion of the food becomes contaminated while it is in wholesale or storage warehouses apart from the point of production, too frequently contamination occurs during production.

Much of the progress in food plant sanitation under FDA programs has been based on the elimination of the more obvious sources of contamination: insects and rodents. Inspection techniques for their detection are relatively simple, and laboratory procedures for the detection and isolation of insect and rodent filth in food have been available for the past 15 years. Emphasis on these factors has encouraged remarkable improvement in (a) surroundings, structure, maintenance, and operation of plants and equipment; (b) cleanliness and soundness, sorting and storing, of raw materials; and (c) plant and laboratory control of raw materials and finished products. It has led to the establishment of sanitary programs as an integral part of food production.

Except in those instances in which contamination with micro-organisms has resulted in clear evidence of danger to health, little has

Figure 2. The scope of accomplishments of the Food and Drug Administration, fiscal 1954.

Bakery warehouse flour being examined by FDA inspector for insect infestation.

been done, or can be done with the staff available, in the bacteriological aspects of food plant sanitation. Foodborne infections and intoxications have not decreased in recent years as have waterborne and milkborne diseases. Much of the foodborne disease probably results from mishandling at the point of consumption. But it may well be that there is more bacterial contamination of foods shipped in interstate commerce than is generally realized. Since the enteric infections transmitted by foods must be regarded essentially as evidence of fecal contamination, the importance of improved sanitation during all stages of food production and handling becomes apparent. A much enlarged complement of microbiologists in the FDA field offices is needed to meet the problems in this area.

The Food and Drug Administration has broad responsibility for the protection of the public against interstate traffic in insanitary foods. As new food products, increasingly in processed ready-to-eat forms, appear on the market, expansion of the Food and Drug Administration of the order recommended by the Citizens Advisory Committee will be neces-

sary to cope with the many new food sanitation problems (3).

Many foods, of course, are sold within the community or the State in which they are produced. Sometimes manufacturers having difficulties with the Food and Drug Administration purposefully restrict the distribution of their products to intrastate traffic. Sanitation of these foods is the problem of State and local officials.

Food sanitation, then, is the concern of State and local officials as well as national officials. The combined efforts of all are necessary to afford the degree of protection from insanitary food the consumer expects and is entitled to.

FDA Nutrition Program

By E. M. NELSON, Ph.D.

The passage of the Food and Drugs Act of 1906, prohibiting adulteration and misbranding of foods, accelerated a consideration of their nutritive value and the advancement of nutrition science. In the first few years of the new law, the adulteration of foods involving the use of poisonous or deleterious ingredients was of primary importance. Foods containing toxic dyes and preservatives were common examples. As adulterated foods of this kind were driven from the market, greater attention was given to so-called economic types of adulteration such as the substitution of non-nutritive fillers, water, or other cheap ingredients for the more valuable food ingredients which the customer expected to find in the foods he purchased.

The knowledge of nutrition in those years did not permit the critical evaluation of the effects of processing and other manufacturing procedures on the nutritive value of our food supply that is commonplace today.

Since 1906, the science of nutrition has advanced more rapidly than in any prior period of time. It was not until the early part of the century that laboratory animals were used in testing the nutritional adequacy of foods. The word "vitamin" was coined in 1911, but it was not until 1926 that products were examined for vitamin content. The isolation, identification, and synthesis of the major vitamins took place in the decade from 1930 to 1940 when the im-

portance of vitamins in our dietary was brought to the fore.

The enactment of the Food, Drug, and Cosmetic Act of 1938 reflected the progress that was being made in the field of nutrition and applied the new scientific knowledge to the protection of consumers. In addition to the basic adulteration and misbranding provisions of the Act of 1906, the 1938 law gave authority to establish legal standards for foods and thus provide for better control of the nutritive value of such products. It required more informative labeling of foods generally and authorized special labeling requirements for foods for special dietary uses.

The policies and regulatory actions of the Food and Drug Administration are designed to provide consumers with the benefits of practical application of reliable nutritional knowledge in the production and labeling of foods, and to prevent consumer exploitation by pseudo-nutritionists and other quacks.

A standard for a food under the Food, Drug, and Cosmetic Act must "promote honesty and fair dealing in the interest of consumers." Under this provision, consideration must be given to the effects of the kinds and amounts of ingredients permitted in a standardized food on its overall nutritional value. This has been of particular significance in considering proposals to add specific nutritive factors such as vitamins and minerals to staple foods.

Fortification of Foods

The Food and Drug Administration has followed a policy that is intended to limit the addition of specific nutritive ingredients such as

Dr. Nelson is chief, Division of Nutrition, Food and Drug Administration.

vitamins and minerals to standardized foods to those instances where there is convincing nutritional evidence that the added nutrients will provide substantial benefits to significant segments of the population.

The addition to foods of specific nutrients already adequately supplied by unfortified common foods is not only wasteful but tends to confuse consumers as to their nutritional needs and the nutritional properties of our food supply.

The need for a basic Food and Drug Administration policy with respect to fortification of foods arose in connection with hearings in 1940 on standards for flour and related products. Many proposals to enrich flour with most of the known vitamins and many minerals were made by various proponents of the flour industry.

The FDA took the position that the addition of a vitamin to flour would not be desirable unless there was evidence that a substantial part of the population consumed a diet deficient in the vitamin in question. Such evidence might be deduced from dietary surveys or from clinical observations with respect to the occurrence of deficiency diseases.

It believed that it was also essential to know whether a food is a suitable vehicle for retention of the vitamin through any processes that may be necessary in preparing the food for consumption. It was important to know too that the fortified product would reach the population that was receiving a diet deficient in a particular vitamin.

If these conditions were met, it was important to add the vitamin in suitable quantities. If flour provided 25 percent of the calories ingested, it seemed proper to require that the quantity of flour consumed daily should contain at least one-fourth of the daily requirement of the vitamin used for fortification. There seemed to be no purpose in adding more than the daily requirement to this quantity.

The principles stated at the 1940 hearings have been generally accepted as the basis for fortifying flour. They have been used as a guide in subsequent proposals to fortify other foods, and they have received support from the Food and Nutrition Board of the National Research Council.

In accordance with a basic policy, legal

standards for the following staple foods, containing added nutritive ingredients, have been established:

Enriched flour.

Enriched bread and rolls.

Enriched macaroni products.

Evaporated milk with increased vitamin D content.

Oleomargarine with added vitamin A.

Enriched corn products.

Standards for the same kind of foods without fortification have also been established. It will be noted that the Federal law does not require enrichment of these foods but leaves to manufacturers and consumers the freedom of choice to select the type desired. A schedule of sampling these standardized foods for vitamin, mineral, and other types of examination to determine compliance is a part of FDA regulatory operations.

Some Regulatory Programs

The degree of attention given to specific types of products will vary from year to year, based on experience and need for broader or more restricted coverage. Regulatory programs have also been developed to provide for the selective sampling for laboratory examination of the numerous vitamin and mineral supplements and other foods for special dietary uses. Since the facilities for laboratory examination of products bearing vitamin and other nutritional claims are limited, other regulatory programs have been developed to protect consumers from exploitation through false and misleading nutritional and therapeutic claims for such articles. These projects are designed to deal with representations which are unwarranted regardless of the nutritional properties of the particular products involved.

Misrepresentations concerning foods, and particularly vitamin and mineral preparations, are a difficult problem for the Food and Drug Administration. Much misinformation has been furnished the public about nutrition and its relation to health. Some of this stems from competition and attempts to gain a sales advantage through advertising and other promotional material based on recent scientific discoveries of undetermined or unestablished

significance. The substantial contribution to consumer misinformation and deception made by nutritional quacks and faddists cannot be overlooked.

An intensified program of consumer education by all those in a position to furnish scientifically sound information about nutrition is necessary to increase the effectiveness of the various Federal and State laws designed for consumer protection in this area.

The broad statement that the food of the American people does not furnish a satisfactory diet is frequently made. The contention is that our soils have been so depleted that they can no longer produce plants of adequate nutritive value or that chemical fertilization of crops has resulted in reduced nutritive value.

These pseudo-scientific statements have an aura of plausibility but little scientific justification.

To only a very small extent is the composition of the parts of plants that people eat governed by the composition of the soil. The composition of the plant and its nutritive properties is controlled primarily by genetic factors which also control its size and shape. Much is made of the destruction of vitamins in cooking and loss of vitamins and minerals when the water in which foods are cooked is thrown away. To be sure, there are losses of this kind, but the facts have been greatly overemphasized. Such losses have been greatly reduced by improved methods of cooking. One must remember that man began cooking his food a long time ago.

Nutritional deficiency diseases in the adult generally result from restricting the diet to a single food or to a very few foods rather than cooking losses. In the Orient, beriberi occurs among populations confined principally to a diet of polished rice. Pellagra and riboflavin deficiencies were observed in the southern part of this country, largely among people whose diets were restricted by their economic status to cornmeal, fatback, and molasses. Their diets have been improved both by changed economic conditions and by a food enrichment program with the result that vitamin deficiency diseases are now rarely seen in this country.

The similarity between the symptoms observed in human beings and other animals suffering from nutritional deficiencies and those

resulting from non-nutritional causes has provided another fertile ground for exploitation of the consumer.

The extremely low incidence of demonstrable nutritional deficiency in this country has made it necessary for those with products to sell to talk in terms of "subclinical deficiencies" which, in less elegant language, means that the condition so described cannot be demonstrated to be of nutritional origin. This device, coupled with statements about the unreliability of our common food supply as a source of nutrients, because of soil erosion, cooking losses, and other similar misrepresentations, is typical of the misuses in which modern nutritional knowledge is being employed.

Foods for Special Dietary Uses

The Food, Drug, and Cosmetic Act recognizes the difficult and technical problems in the labeling of vitamin preparations and foods used in the management of disease. Section 403 (j) of the act gives the Secretary of the Department of Health, Education, and Welfare power to promulgate regulations to cover the labeling of those products. It also requires that the labels of vitamin preparations show the vitamin content. Section 403 (j) reads:

"A food shall be deemed to be misbranded if it purports to be or is represented for special dietary uses unless its label bears such information concerning its vitamin, mineral, and other dietary properties as the Secretary determines to be, and by regulation prescribes as, necessary in order fully to inform purchasers as to its value for such uses."

Biochemists generally regard vitamins as foods since they are essential nutrients, needed for growth and maintenance of the body. Only minute quantities are needed daily. Since pharmaceutical manufacturers have equipment and personnel trained to handle such small quantities, vitamin preparations ordinarily fall into drug channels for distribution and marketing.

Vitamins are usually measured in units, milligrams, or even micrograms—terms unfamiliar to many laymen. To meet the requirements that labeling for foods for special dietary use must fully inform the purchaser, "minimum daily requirements" have been established for vita-

mins. The vitamin content of a preparation must be stated on the label in terms of the proportion of the minimum daily requirement provided in the recommended daily intake. The quantities of the four minerals, iron, calcium, phosphorus, and iodine, which before 1940 were the most frequently used supplements to the daily diet, must also be declared in the same manner.

Infant foods must be labeled to show all ingredients. Since the feeding of infants often presents problems, it is important that infant foods bear all the information necessary for their use. Labels of other foods are not required to name the spices, flavorings, or coloring material present. The label of a product that is a complete or partial substitute for human milk must state that additional quantities of vitamins C and D and of iron must be supplied from other sources if the quantities present are not adequate. The label must bear a quantitative declaration of vitamins A, B₁, C, and D, and must list the percentages by weight of water, protein, fat, available carbohydrates, crude fiber, calcium, phosphate, and iron.

Many foods are offered for control of body weight, particularly by reducing. The label of a food for the control of body weight or the dietary management of disease must state the percentages by weight of protein, fat, and of available carbohydrates as well as the number of available calories in a specified quantity.

If crude fiber is represented to be of significance in a food, the percentage by weight must be declared on the label. If saccharine or a saccharine salt is used in a food in lieu of sugar, the label must bear the statement, "Contains -- saccharine (or saccharine salt, as the case may be), a non-nutritive artificial sweetener which should be used only by persons who must limit their intake of ordinary sweets." The weight of saccharine or saccharine salt is inserted in the blank.

If a food is for special dietary use because of reduced allergenic properties, the label must bear the common or usual name of each ingredient, including any spice, flavoring, or coloring used. The label must also contain a statement indicating the nature and effect of any process to change the allergenic properties of the food or its ingredients.

All of these requirements are contained in the food and drug regulations promulgated in 1941. The regulations have served their purpose well, but now they are somewhat outdated and in need of revision and extension.

A few years ago the labeling of foods with reduced sodium content became an important problem. It was shown that a reduced sodium intake was more important in the control of blood pressure than had been realized. Many foods on the market labeled "No salt added" contained considerable quantities of sodium from other sources although it was a statement of fact that no salt had been added. Some contained considerable amounts of sodium as a natural constituent. Sodium glutamate, which is used extensively for flavoring, and sodium propionate, which is an effective mold inhibitor, may contribute unsuitable quantities of sodium.

Foods labeled "No salt added" are attractive to a person seeking low sodium foods, but they have little value for the purpose desired. Such representations are, of course, misleading. There are a number of ways in which foods may pick up sodium in the process of manufacture, and producers of foods that are offered for the benefit of persons on a low sodium diet should determine the actual sodium content of the food.

The regulations require that if a food is represented to be of value because of a low sodium or low salt content, it must be labeled to show its sodium content in milligrams per hundred grams of food as well as per serving.

The Division of Nutrition

The Division of Nutrition of the Food and Drug Administration is responsible for the development of scientific facts and opinions concerning nutrition as a basis for the policies and regulatory activities of the FDA. It also examines official samples for vitamin or other nutritional properties, by means of biological, microbiological, or chemical procedures which cannot be performed in the field laboratories of the FDA.

Under normal circumstances, the division's work is about equally divided between strictly enforcement operations and specialized research designed to facilitate or improve FDA enforcement of the Federal Food, Drug,

and Cosmetic Act. Research activities of the division have been limited almost entirely to the development or improvement of assay procedures for enforcement purposes. There is little incentive to do this kind of research in other nutrition laboratories. Such research has made possible a more rapid and precise examination of a greater number of samples without an increase in manpower.

The manufacturers of vitamin preparations have a very similar problem, and there has been excellent cooperation with industry laboratories in the study and development of control methods.

It is necessary that the Division of Nutrition keep abreast of the scientific developments in the field of nutrition. This is accomplished by a study of the scientific literature, communications and consultation with outside authorities in the field, and by attendance and participation in the activities of scientific societies and associations. It must also be alert for developments in manufacturing and labeling practices which may require changes in policies and regulatory activities in order to recommend such changes to the Commissioner of Food and Drugs.

In the case of litigation involving products examined in its laboratory, the division must be prepared to provide convincing scientific evidence of the deficiency suitable for presentation in the Federal courts. The division's analysts who are called upon to provide such testimony must be so qualified by training and experience that their evidence can successfully withstand cross examination.

In cases involving false and misleading claims about the nutritive or therapeutic value of vitamins, minerals, and other food factors, various members of the Division of Nutrition are called upon to testify as experts and must therefore be prepared to qualify as such in court. Among other things, they must have a comprehensive knowledge of the views of other experts in the field so that they may testify as to what constitutes the consensus of scientific authorities in the field of inquiry. Such qualifications are likewise of utmost importance to the work of the Food and Drug Administration, to the end that its actions and policies will be in accord with the best scientific knowledge available and enjoy the support of the outstanding authorities in the field of nutrition.

Fourth Annual Symposium on Antibiotics

The Fourth Annual Symposium on Antibiotics, sponsored by the Division of Antibiotics of the Food and Drug Administration, Department of Health, Education, and Welfare, with the journals, *Antibiotics and Chemotherapy* and *Antibiotic Medicine & Clinical Chemotherapy* will be held on October 17-19, 1956, at the Willard Hotel, 14th Street and Pennsylvania Avenue, NW., Washington, D. C.

To allow the program committee time to review material for presentation and to facilitate publication of the *Antibiotics Annual* 1956-57, manuscripts must be submitted by September 17, 1956.

For further information, address Dr. Henry Welch, director, Division of Antibiotics, Food and Drug Administration, Washington 25, D. C.

New Problems of Food Safety

By FRANK A. VORHES, Jr., B.S., and ARNOLD J. LEHMAN, M.D., Ph.D.

The safety of food has been of concern to man from the very earliest times. Whether through instinct or intelligence, by trial and probably sometimes fatal error, forgotten benefactors of the race must have learned to eat substances that would not harm them; and they must have conveyed that knowledge to others, else we might not be here to speculate in this vein. Though probably accumulating slowly, a wealth of information regarding food safety had developed by the dawn of recorded history; witness, dietary customs and taboos reflected in the most ancient of ecclesiastic law.

With a few exceptions, those substances, natural or unnatural, that result in immediate acute harm are not the cause of food safety problems in modern civilization. Rather, it is the insidious hazard of chronic toxicity that is the most serious concern today, a hazard that demands a far more subtle and searching approach.

Current food safety problems arise in large part as a result of technological progress in food production, processing, and distribution. To meet economic pressures, the agriculturalist, that traditional conservative, must now intensively apply many types of advanced technology. His partner in "agribusiness," the food processor, is, of course, no novice in this field. Their joint accomplishment during the past sev-

eral decades is abundantly apparent in the ample quantity, high quality, and appetizing variety of foodstuffs available to the American public. Nonetheless, in the very nature of the progress that has brought these benefits, hazard to food safety is inherent. That fact does not necessarily mean that harm is actual or even imminent; but it does mean that need for gauging the existence and immediacy of danger is genuine and pressing.

One important group of current food safety problems stems from employment, in food production, of a long and lengthening series of chemical adjuvants—insecticides and insect repellants, fungicides, herbicides, defoliants, plant growth regulants, animal growth stimulants and medicaments, crop protectants and fumigants. These substances are commonly of complex, sometimes uncertain, and even occasionally unknown chemical identity. One of the problems in this area is to ascertain whether food exposed to them is contaminated and to gauge the degree of contamination.

In processing, food may receive preservatives, antioxidants, colors, bleaches, flavors, coatings, drying agents, moistening agents, thickening agents, sequestering agents, "aging" agents, stabilizers, emulsifiers, neutralizers, acidifiers, sweeteners—in short, retainers, modifiers, and inhibitors of virtually every property natural food may exhibit. (But we don't mean to imply any opposition whatever to genuine improvement per se.)

Associated with food production and processing are new equipment cleaners, sanitizers, and lubricants, new surfacing materials, and new alloys composing the equipment itself, any of which may get into the product.

Mr. Vorhes is chief of the Division of Food, and Dr. Lehman is chief of the Division of Pharmacology, Food and Drug Administration.

Today's food packages, incorporating new plastics, enamels, films, and tissues, with their own plasticizers, antioxidants, catalysts, impregnants, coatings, and the like, are still another potential source of additives to the very food which these materials are intended to protect from contamination.

Some anonymous philosopher has said that he who can get a corner on a food production adjuvant, used in even relatively minute quantity in this multibillion-dollar commerce, has his fortune made. Indeed, the benefit to their sponsors seems likely to prove the only net advantage of some proposed food additives. But we need not consider those wholly undeserving suppliants for entry into our food supply. Nor need we concern ourselves with most of those natural substances that have been tested through long years of use. Entirely aside from these, the novel and substantially artificial food additives that may be conceded some real functional merit are so many that an informed observer has no doubt whatever that they present food safety uncertainties. It is estimated that some 25,000 chemical additives have been considered for use in food since 1940 (see chart).

Safeguarding the Physically Subnormal

Set aside for the moment (but don't forget) the fact that there is a large and growing backlog of study to ascertain food contamination from its production and processing adjuvants and to evaluate the toxicity of the adjuvants to normal adults in good health. Aside from that aspect, it remains generally to be determined what their effect may be on persons in subnormal physical condition.

No person is expendable within the meaning of the Federal Food, Drug, and Cosmetic Act. In a very significant decision (233 U. S. 399), the Supreme Court said that the food at issue "may be consumed . . . by the strong and the weak, the old and the young, the well and the sick; and it is intended that if . . . because of any added poisonous or other deleterious ingredient, [it] may possibly injure the health of any of these, it shall come within the ban of the statute."

Orthodox techniques and procedures of toxicology are not well suited to establishing that

a substance is safe for persons with varied types of physical impairments. Pharmacological investigation ordinarily proceeds on the basis of observable effects produced by administering the test substance to cloistered, well-fed and well-cared for, normal laboratory animals. However appropriately the findings so obtained may be interpreted in application to the human norm, there may be valid reservations to translating them into terms of effect on health of unusually susceptible individuals. The Supreme Court decision cited allows those responsible for safeguarding the food supply scant liberty to indulge in the educated guess or the calculated risk.

This consideration comes to a particularly critical focus with respect to milk, which may represent the principal component of the diet of babies, old folks, and invalids. The law authorizes establishment of tolerances for residues of useful pesticides "to the extent necessary to protect the public health." One may not assume that pesticides don't get into milk merely because no one purposefully puts them there. Pesticides are useful in production of feed and fodder crops, on dairy premises, and on lactating animals themselves. Some of them, particularly some halogenated hydrocarbons, when ingested or absorbed through the skin of animals, are known to appear in the milk—sometimes unchanged, sometimes modified by reaction within the animal system. One must consider whether residues of other pesticides so employed may perhaps have escaped detection in milk because the parent compound metabolizes to another toxicant unresponsive to methods of analysis so far employed. Under these circumstances there may be only an obscure basis, generally, on which to set tolerances for residues of pesticides used in connection with milk production.

The possibility exists, of course, that use of a pesticide would not contribute contamination to milk, but this raises other quite practical questions. For example, how does one ascertain that no residue whatever is present in a food? By analysis? That tool of science is designed to determine the presence of a substance, not its absence. It is capable of demonstrating some minimum concentration of a specific entity, such minimum being fixed by the limit of

SIZE OF PRESENT PROBLEM

delicacy of the analytical procedure. It cannot show, at least not directly, whether a lesser concentration exists or whether some substance unresponsive to the method is present. Before an adequate method of analysis can be selected or devised, a decision must be reached as to what concentration is of minimum significance, a decision that is practically equivalent to establishing the threshold of contamination. So one may be right back at the starting point. A gauge of harmfulness of the pesticide to the more susceptible segments of the population is ordinarily basic to justification of use of any pesticide, whether it is directly or indirectly associated with dairy practice.

The Biochemical Approach

We cannot offer solutions to these problems, but we can suggest that an improved understanding of reactions that food additives may undergo in the animal (and human) system would contribute substantially. Were it possible to predict the character and extent of biochemical reactions that may cause harm, together with the reactions fostering protection

and recovery, not only would toxicological observations be most usefully supplemented, but uncertainties of analytical procedure might also be clarified. The first step would be to ascertain the route and fate of the ingested food additive. This may seem elementary, but such approach has too often been ignored or has been given but scant consideration. Application of the biochemical approach in the study of pesticides that inhibit cholinesterase activity furnishes a relatively recent and encouraging example of its value. At feeding levels much below those resulting in minimal tissue abnormality, these substances have been shown to lower, drastically, the activity of the important body enzyme, cholinesterase. Techniques by which this more delicate index of their harm was established have been adapted to methods of measuring the concentrations of their residues.

Some verbally resourceful investigator, seeking to explain the unexplainable, invented the term "subclinical symptoms." We are indebted to him for expression of a concept pertinent to food safety problems. The specter of as yet unmanifested harm from food additives may

not safely be laid to rest in routine fashion; and it may become a quite personal threat. Most of us have children; some have dependent invalids; many have grandparents; and all may hope to join the ranks of elder citizens. For any of these the ghost of subclinical symptoms may materialize, with tragic consequence, unless understanding of effects of food additives can keep pace with their increasing usage.

Another of the food additive problems, one that is virtually untouched by investigation, concerns the number and variety of the substances in use. In the aggregate they represent almost infinite possibilities for combinations of novel substances in the human diet. It seems hardly conceivable that there would not be some in which the effect of combined toxicants would be not only additive but synergistic.

Obviously, progress in exploring this problem by hit or miss testing of each possible combination, in a sufficient range of relative proportion, could be far beyond any foreseeable resources. However, improved understanding of biochemical reactions might go far in expediting useful findings. At least some examples of the phenomenon of synergism may reflect only associated biochemical reactions in which one agent reacts to produce the primary harm, while another impedes normal resistance or recovery mechanism. If this be even a rough explanation of synergism, quite unanticipated consequences could arise from combinations of toxicants, each present at a level which by itself would warrant no concern.

Cold Sterilization

It would hardly be possible, these days, to discuss food-safety problems without bringing to mind those that could conceivably stem from what many informed food technologists believe to be a promising application of atomic energy, that is, so-called cold sterilization. This is accomplished by exposure of food to ionizing rays, either gamma rays, which are not basically different from the more familiar X-rays, or beta rays, which are simply fast-moving electrons. Nothing of significant substance is added to the food so processed; energy alone is imparted to it. Energy in this form produces in organic matter the effect of ionization. Ionization is a

molecular change that increases chemical reactivity. Consequently, chemical reactions occur in food as a secondary result of its irradiation. One product of such reactions is peroxide, not only the simple and familiar hydrogen peroxide but peroxides of other kinds, perhaps including those of most complex molecular structure. There is yet no assurance, and it is theoretically improbable, that reactions occurring are solely those producing peroxides. On the contrary, at this stage it appears more likely that the induced reactions are substantially heterogeneous rather than specific.

We disclaim any special knowledge in this area. Although the Food and Drug Administration has not hesitated to cooperate in an advisory capacity on questions within its competence, its responsibilities do not ordinarily extend to active participation in development of new processes. But new processes for food invariably pose potential food safety problems, and, accordingly, the agency always has been an interested observer of such developments.

We were reasonably well assured quite early, from information we received, that there was very remote possibility, if any, of inducing radioactivity in food by exposing it to such levels of radiant energy as are at all likely to become available, or even practicable, for such use. There has been no serious proposal whatever for the direct addition of radioisotopes to food. Radioisotopes, if used in cold sterilization, would be used solely as sources of radiant energy. Actually, at least some investigators of cold sterilization appear to favor mechanical generation of the energy, as more practical than deriving it from radioisotopes. There is room for appropriate concern, of course, that disposal of atomic wastes could result in contamination of water supplies and thereby introduce a threat to safety of the diet. Precautions so far taken, and realistically to be expected, appear to foreclose any immediate prospect of food hazard from such source. However, it will take constant vigilance to maintain that satisfactory situation.

Development of cold sterilization thus far has shown no essentially new or mysterious type of food safety problem. The energy, the application of it, and the mechanism of its

FDA inspector collecting import sample of meal at pier.

effect are new; but the end result seems to be of a quite familiar nature—the appearance in food of new and largely unknown chemical substances. Although probably much more complex, the problem seems basically of the same kind as those stemming from use of new chemical adjuvants in food production.

Radiant energy holds promise of production practicability for such objectives as preventing the sprouting of potatoes, killing trichina organisms in pork and insects infesting grain, pasteurizing a variety of foods sufficiently to extend their life very substantially without refrigeration, and retaining prominent elements of freshness in meat and other commodities.

Energy requirements for accomplishing these purposes vary. Sprouting of potatoes, for example, is inhibited at relatively low energy input; sterilization of micro-organisms generally requires almost 10 times as much. As energy

requirements increase, so do unfavorable side effects. The process is not promising for milk, for example, because of disagreeable flavor changes produced by energy input far lower than enough to pasteurize. Nutrient values are also affected at energy input sufficient to sterilize. Vitamins A, thiamine, riboflavin, pyridoxine, B₁₂, ascorbic acid, and niacin are destroyed in varying degree, and some alteration in nutritive value of protein has been observed.

The observed organoleptic and nutrient changes in products subjected to cold sterilization confirm that expected chemical reactions do take place. They signify the possibility, if not the probability, of a wide variety of reactions and, hence, a wide variety of end products. Common prudence dictates a concern as to the identity of such end products. These are food additives, for all practical purposes. Good practice in toxicological investigation involves

feeding of experimental animals at a high level of a proposed food additive, with the objective of discovering the nature of definable injury, a middle level which may or may not give evidence of injury, and a lower level which does not affect the animal. The data so obtained permit an estimate of the margin of safety of the additive in use. Sole reliance on findings of orthodox toxicological study of irradiated foods themselves, in ignorance of both the identity and quantity of substances therein that may influence such findings, invites valid reservations to any final conclusions.

It can hardly be overemphasized that the problem of appraising the safety of cold sterilization is complex, of wide scope, and demanding of very considerable investigative resources. A great deal of work has been done on it, and significant progress has been made. It does not appear, however, that the safety of the process is anything like as near being established as is its production practicability.

Antibiotics as Adjuvants

One class of potential food production adjuvants that does not currently constitute a problem in the same sense as the others discussed is the antibiotics. We have a sufficient gauge of their deleterious properties to conclude that, in food as consumed, their presence in virtually any concentration whatever is unjustified.

The wide and valuable usage of antibiotics in medicine is well known. The reasons for their curative efficacy are precisely the reasons that make them effective preservatives: They combat development of bacteria, the prime cause of food spoilage. It is not so generally appreciated that their medical usage is attended by distinct hazard of sensitization, varying in degree with different antibiotics. To the individual who is or has become sensitized, administration of an antibiotic may cause serious illness or even death. A method of developing sensitization is by administering the agent in small repeated dosage, in a manner paralleling that of repeatedly ingesting food preserved with an antibiotic. The use of antibiotics as food production adjuvants in ways

such that they actually are consumed is therefore manifestly contrary to the public interest, and the Food and Drug Administration has formally so declared.

However, there are a few justifiable uses of antibiotics in food production or processing. For example, it has been shown that fresh dressed chicken cooled in ice water containing 10 p.p.m. chlortetracycline will not absorb more than 7 p.p.m. of the antibiotic in any portion of the flesh, and that more than 99 percent of this pickup will be destroyed by any type of cooking sufficient to make the chicken suitable for consumption. The cooked treated chicken exhibits antibiotic activity no greater than that of untreated chicken. On this evidence, a tolerance of 7 p.p.m. of chlortetracycline, not to be exceeded in any part of the flesh, has been established for raw chicken.

Conceivably, there may be other, equally safe, food uses of antibiotics, but they would need to be equally well supported by fact in each case. It seems improbable, at this time, that many such instances could arise.

Summary

Chemical additives, whether they be intentionally put into food or the incidental result of food production or processing procedures, are today the major cause for concern with respect to the safety of food. And it is the uncertainty surrounding these substances and their effects rather than any knowledge of actual harm that is the main reason for concern. In particular: What are the effects on persons with physical impairments? What are the effects of the multitude of combinations of the many substances in use?

In discussing any problem without at the same time describing measures taken toward its solution, or ancillary controls in effect pending final solution, it is difficult to avoid exaggerating the immediacy of evils the problem may involve. We have no wish to be alarmists. Our purpose has been to examine objectively some of the elements of needed knowledge that would contribute to understanding food safety problems.

Control of Pesticides on Food

By WINTON B. RANKIN, M.S.

Pesticides are today considered essential for the production of an adequate, high quality food supply. But pesticides are poisons, and some of them, if not used properly, may leave harmful residues in or on food. In fulfilling its responsibility to protect the public from the addition to food of poisonous or deleterious substances, the Food and Drug Administration is therefore concerned with pesticides. Its objective is to limit pesticide residues to amounts that will be completely safe for consumption. It is concerned primarily with the possibility of chronic poisoning, rather than of acute poisoning, since the quantities of residues are ordinarily minute.

In accomplishing this objective, the Food and Drug Administration establishes tolerances for pesticide residues; that is, it sets the amount that may remain legally on crops shipped in interstate commerce. Establishment of a tolerance means that the pesticide can be employed usefully in agriculture, that residues within the tolerance are safe, that when the pesticide is used properly it will leave residues that are within the prescribed limit, and that crops shipped in interstate commerce shall not bear residues exceeding the prescribed limit. FDA may exempt a pesticide from the requirement of a tolerance if it finds that the pesticide will not leave poisonous residues.

Mr. Rankin is assistant to the Commissioner of Food and Drugs in charge of the pesticide chemicals program. He has been with the Food and Drug Administration since 1939.

The first regulations listing formal tolerances for pesticides were issued in March 1955. These tolerances were set under a public hearing procedure that required the Department of Health, Education, and Welfare to determine not only what level of residue is safe, but also that the pesticide is necessary in the production or handling of crops. This procedure was not particularly satisfactory to anyone. It was cumbersome and it required a health agency to make agricultural decisions.

Today, tolerances are established under a Federal law enacted in 1954, the pesticide chemicals amendment to the Federal Food, Drug, and Cosmetic Act, also known as the Miller amendment. This law provides new, more convenient procedures for determining how much poisonous agricultural spray or dust may remain safely on crops. It recognizes that sprays and dusts are necessary to insure a continuing supply of high quality foods, and it is designed to permit the effective use of these materials without hazard to the consumer. It assigns agricultural functions to the Department of Agriculture and health functions to the Department of Health, Education, and Welfare. It does not, however, make any change in the basic requirement that foods in interstate commerce shall be free of dangerous quantities of pesticide residues, which is a part of the Federal Food, Drug, and Cosmetic Act.

The new law provides that, within its jurisdiction, a raw agricultural commodity shall not be marketed if it bears a residue of a pesticide chemical, except under one of the following conditions:

1. The pesticide chemical is generally recognized by experts as safe.

2. The Government has established a safe tolerance for the residues of the pesticide chemical, and the residues remaining on the food are within this tolerance.

3. The Government has exempted the pesticide chemical from the requirement of a tolerance.

(For practical purposes a raw agricultural commodity is a crop as it is harvested, and a pesticide chemical is a substance that will destroy or control pests such as insects and weeds. More exact definitions are given in the law itself.).

How the Law Works

There are three principal steps leading to the establishment of a tolerance under the new law:

1. A manufacturer of a pesticide (or any other interested party) submits a petition to the Food and Drug Administration requesting the establishment of a tolerance, a copy of which he sends to the Department of Agriculture requesting certification that the pesticide is useful for the purpose for which a tolerance is sought. In the petition, he must supply information about how he proposes to use the pesticide, the quantity of residues that will remain on the foods, and the toxicity of the residues when they are consumed throughout the life of test animals, such as rats or dogs.

2. Department of Agriculture scientists determine whether the pesticide is useful in agriculture when employed as proposed by the petitioner. If they find that it is, the Department transmits to the Food and Drug Administration a certificate of usefulness and also its estimate of the residues that are likely to remain on the foods.

3. Food and Drug Administration scientists study the experimental data given in the petition and all other available information, including that from the Department of Agriculture. On the basis of this study, FDA establishes a tolerance that meets both the requirements of safety and the needs of agriculture. The tolerance is set forth in a regulation published by the Commissioner of Food and Drugs. Residues within this amount may legally remain in or on the crops to which the tolerance applies.

The same procedure is followed in exempting a chemical from the requirement of a tolerance.

Thus far, formal tolerances or exemptions have been established for almost 100 pesticide chemicals. When the Miller amendment becomes fully effective on July 22, 1956, all pesticides will fall in one of four classes:

Safe chemicals. These may be used without a tolerance or an exemption, because they are not considered poisonous as used on crops. Sulfur, lime, and lime sulfur are in this group.

Chemicals exempted from the requirement of a tolerance. These are considered poisonous, but they are exempted for use on growing crops because excessive or harmful residues will not occur when they are so used. Many copper compounds and pyrethrins are among the materials in this group. (As yet, no pesticide has been exempted for postharvest use.)

Chemicals with a zero tolerance or its equivalent. Some of these, such as mercury- and selenium-containing compounds, are so toxic that no residue whatsoever should remain on food as it is marketed. Others in this group have not been studied enough to show whether they deserve a higher tolerance. Still others, such as tetraethylpyrophosphate, can be employed usefully in agriculture without leaving residues at harvest time. Any pesticide not specifically included in another group has the equivalent of a zero tolerance.

A zero tolerance does not mean that the chemical is barred from use in agriculture; it means that it must be used in such manner that no residue will remain when the crop is shipped.

Chemicals with tolerances higher than zero. Tolerances higher than zero have been set for numerous chemicals which are safe if the residues are kept within a certain limit but which are not safe for uncontrolled use. The tolerance for a chemical applies only to specific crops. The fact that a tolerance is in effect for one crop does not mean that residues of the same chemical may remain on another crop.

According to the Federal Insecticide, Fungicide, and Rodenticide Act of 1947, all "economic poisons" must be registered with the Department of Agriculture before they are shipped in interstate commerce. The directions for use on labels of pesticides thus registered should yield crops with residues within the tol-

erances set by FDA. Growers, therefore, have one simple rule to follow: They should use pesticides according to the label directions—on the crops specified, in the amounts specified, and at the times specified.

Enforcement Procedures

The Food and Drug Administration enforces the Federal law with regard to pesticide residues on foods as follows:

Before the growing season, it studies new developments with regard to pesticides and new recommendations in spray schedules issued by the State agricultural authorities. During the growing season, FDA inspectors keep in touch with State authorities and growers to determine what sprays and dusts are used and how. The inspectors may pick up a few samples from farms, shipping points, or produce markets for laboratory examination to determine the accuracy of earlier tentative conclusions about the quantity of the residues remaining.

When the inspectors visit a growing area, they go openly. They cooperate with the State and local agricultural authorities, and they make every effort to be helpful. Unfortunately, the FDA laboratory facilities are extremely limited and cannot make tests for pesticide residues for all those who would like to have such tests made. However, if any of the samples collected from farms show high residues, the appropriate State authorities are immediately alerted so that steps may be taken to reduce the residues before the crop is shipped. Two examples of such preventive measures and their effectiveness may be cited.

In the fall of 1955, FDA learned that some growers in Texas were planning to use a chlorinated hydrocarbon pesticide on cabbage approximately 2 weeks before harvest. Past experience had indicated that application of this chemical that close to harvest would yield toxic residues. FDA notified its nearest field office, the United States Department of Agriculture, and the manufacturer of the pesticide chemical. The Department of Agriculture telephoned State agricultural officials, and they, in turn, warned the county agents. The manufacturer notified insecticide formulators in the area and asked them to help prevent misuse of the ma-

terial. An FDA inspector went immediately to the area and warned the growers at a meeting and by television and radio. As a result, the chemical was not used as planned, and the cabbage crop, when harvested, was safe for shipment.

In another case, some growers sprayed their lettuce with a pesticide the residues of which are not permitted on this crop. The rate of application recommended by the State was doubled, and harvesting was started too soon after spraying. FDA found that there were high residues of the chemical on the lettuce as harvested. It notified the State authorities immediately, and the State authorities directed the growers to trim the lettuce severely at harvest to remove the outer leaves containing the poison. One grower shipped two carloads of lettuce without trimming it, and they were seized by the FDA.

FDA would much rather prevent violations than seize crops. Seizure action is reserved for extreme cases. Ordinarily, preventive measures are adequate to insure the shipment of satisfactory produce.

In commenting on seizures, George P. Larrick, Commissioner of Food and Drugs, said: "Growers do not have excessive spray residues on their crops when they observe proper precautions in using agricultural sprays and dusts, but misuse of such chemicals can leave poisonous residues that make a crop illegal in interstate commerce."

State and local health departments will continue to receive reports of injury and illness attributed to pesticide residues in food. In many instances investigation will show that pesticides are not at fault.

However, there may be occasions when misuse of a pesticide will leave dangerous residues on food. In these instances the health department can be of great value to agriculturalists and to the Food and Drug Administration by determining, among other things, what pesticide was employed, when it was applied to the crop, what rate of application was used (generally in pounds of actual pesticide per acre of crop), what stickers, spreaders, or adjuvants were employed with the chemical, when the crop was harvested, and what methods were em-

ployed to reduce the residue, such as washing or brushing or discarding of outside leaves of such crops as cabbage and lettuce. This type of information will help those responsible for recommending spray schedules to determine whether present label directions on pesticides are in need of revision.

An example of the type of misuse that may cause difficulty occurred last year in southern California: To control aphids, a grower sprayed a field of mustard greens with nicotine sulfate solution a few hours before harvest. The nicotine sulfate was old and the grower assumed that it was weak. He prepared a spray twice as strong as recommended. Then, because the

aphid infestation was heavy, he applied it at four times the recommended rate per acre. The mustard greens were harvested less than 24 hours after spraying and marketed immediately. State and local health authorities embargoed outstanding lots of the greens when they began causing illness. Samples of the greens contained 70 to 90 parts per million of nicotine.

FDA appreciates reports of this type of misuse. They will help determine how well established tolerances are being met in actual practice. Reports may be sent to the nearest FDA district office or to headquarters in Washington, D. C.

Research in Cancer Chemotherapy

Under contract with the Public Health Service, five laboratories are engaged in large-scale screening of chemical compounds in the search for drugs useful in treating cancer. It is expected that they will test approximately 2,000 compounds by July 1, 1956.

The laboratories, which began work early this spring, are: Microbiological Associates, Bethesda, Md.; Wisconsin Alumni Research Foundation, Madison, Wis.; Southern Research Institute, Birmingham, Ala.; Hazleton Laboratories, Falls Church, Va.; and Stanford Research Institute, Menlo Park, Calif. The Cancer Chemotherapy National Service Center of the Public Health Service National Cancer Institute has the responsibility for supervising the contracts.

Each compound will be tested against three different kinds of mouse tumors implanted into various strains of mice bred for cancer susceptibility, under procedures for animal screening established by a panel of the Cancer Chemotherapy National Committee. This committee, representing the leading organizations and Government agencies in the field of cancer research, was established in May 1955 to sponsor a national voluntary program of cooperative research and development in cancer chemotherapy.

At present, surgery and radiation are the only means of achieving cancer cures, but some forms of cancer, such as acute leukemia, are not amenable to these treatments. Other forms may be diagnosed only after they have spread throughout the body, too late to be benefited by either surgery or radiation. In such cases, chemical treatment appears to offer the greatest hope. Compounds now in use have been successful in prolonging the useful life of patients suffering from cancer of the breast or prostate or cancer of the blood-forming tissues, but these compounds are not curative.

Certification of Coal-Tar Colors

By G. ROBERT CLARK, Ph.D.

Use of toxic dyes in food was one of the public health problems which led to the passage of the original "pure food law" in 1906. Today, 50 years later, protection of the public from dyes that are harmful to health is still an important purpose of the Federal food and drug legislation.

The Federal Food, Drug, and Cosmetic Act of 1938 provides that coal-tar colors used to color any products subject to the act, except hair dyes, must be from batches certified for such use under regulations promulgated by the Secretary of Health, Education, and Welfare. It characterizes food, drugs, and cosmetics containing uncertified coal-tar colors as adulterated. The law applies both to products manufactured in this country and to imports.

The term "coal-tar color" as used for purposes of the law means any coloring matter that is or may theoretically be derived from coal tar. It has continued in the language since the days when coal tar was the only source of many organic chemicals that are now obtained from various sources, particularly petroleum. The word "color" is usually used instead of "dye" because, in the trade, the word "dye" refers only to soluble material; it does not include insoluble material such as that used to color face powder. However, the two words are frequently used without this distinction.

Dr. Clark is chief of the Division of Cosmetics, Food and Drug Administration.

Coal-tar colors are made from a number of chemical compounds called intermediates. If these intermediates have one thing in common, it is their high toxicity. Almost all dye intermediates are known to be poisonous.

Many of the thousands of known coal-tar colors are extremely toxic when taken internally. Some are irritants and sensitizers when applied to the skin. Some are carcinogenic. Actually, comparatively few colors have ever been tested to determine their safety for use in foods, drugs, and cosmetics. Colors need to be so evaluated, of course, only if such use is contemplated.

Dyes, like many other chemicals, are manufactured in reaction vessels from chemical compounds that, in turn, have been manufactured. In these processes, the dye may pick up such materials as lead, arsenic, mercury, cadmium, or chromium. For most uses, these do no harm, but in food, drugs, or cosmetics, they are likely to be a hazard to health.

From this brief description of coal-tar colors, it is obvious that food, drugs, and cosmetics should contain only thoroughly tested colors. The colors themselves must be nonhazardous, and they must be free from harmful quantities of contaminants. The provisions of the Federal Food, Drug, and Cosmetic Act that require certification of coal-tar colors were designed to make certain that only "harmless" dyes are used in products subject to that act.

The color certification program of the Food and Drug Administration is designed to carry out the provisions of the act pertaining to coal-tar colors. This program, which is one func-

tion of the Division of Cosmetics, is set up to do the following:

1. To list colors as certifiable when there is evidence to show that they are harmless and suitable for use, and that practical and accurate methods of analysis are available. New colors are added only on the basis of specific requests by manufacturers.

2. To conduct such analytical and investigative work as may be necessary to certify batches of coal-tar colors. Certificates are issued for individual batches on the basis of analyses of samples submitted by the manufacturer.

3. To conduct enforcement activities to insure compliance with the law.

Fees for certification based on the weight of the batches are paid by the manufacturer. These fees equip and maintain the certification service.

It is the aim of the Food and Drug Administration to achieve the following with respect to coal-tar colors:

1. Each color listed as certifiable must be completely characterized chemically. A sample of each batch manufactured must be completely analyzed chemically to make certain that it does not differ materially from the material submitted to pharmacological testing.

2. Each color listed as certifiable must have been thoroughly evaluated by pharmacological investigation. This investigation must show that the color is harmless and suitable for use.

Almost constant investigations are carried on in the attempt to realize this optimum state of affairs. When new techniques of analysis become available, they are applied to coal-tar colors.

History of Color Certification

Official recognition of the possibility of hazard to health in the use of synthetic dyes in food was evident as early as 1900. The appropriation for the Bureau of Chemistry of the Department of Agriculture, May 25 of that year, included funds "to enable the Secretary of Agriculture to investigate the character of proposed food preservatives and coloring matters, to determine their relation to digestion and health and to establish the principle which should govern their use. . . ." Several Food

Inspection Decisions issued under this authority were in respect to foods offered for import into the United States. These decisions required notification of the addition of preservatives and colors to foods and freedom of such additives from deleterious properties.

Certification of colors used in food was begun in 1907, when the Federal Food and Drugs Act of 1906 became effective. Under this act, a list of colors permissible for use in food was adopted by the Board of Food and Drug Inspection, and certification of batches of these colors by the Department of Agriculture was optional with the manufacturer. Use of non-certified colors could not be a basis for regulatory action unless it could be shown that the food might be injurious to health by reason of harmful components of the colors used. It was not until 1939 that certification of batches of colors became mandatory and certification of colors used in drugs and cosmetics was begun.

The rules originally used in selecting colors for food, as stated in 1912 by Dr. Bernard C. Hesse in the Bureau of Chemistry Bulletin No. 147, were as follows:

Rule I: All colors which have not been physiologically tested either on man or animals shall not be permitted for use in foods.

Rule II: All colors which have been examined but with contradictory results shall not be permitted.

Rule III: All examined colors which are doubtful shall not be permitted.

Rule IV: Only those colors on the United States market in 1907 which are of definite composition and which have been examined with favorable results shall be permitted.

The adoption of colors today is based on the same principles. However, the tests applied are much more rigid and extensive than those used in 1907.

Under the original color regulations, certificates for individual batches of colors were issued by the Department of Agriculture on the basis of an affidavit of analysis by the manufacturer and a second affidavit of analysis by a competent scientist. These certificates were not based on analyses made by the Department; rather, they were approvals of the affidavits submitted by the manufacturer. Later actions set up a system of certification of batches based on

analyses made by the staff of the Department. This system made possible standardization of methods, and it is the basic system in use today.

From time to time, additional colors were added to the original list. Two colors, butter yellow (*p*-dimethylamino-azobenzene) and Sudan I (1 phenylazo-2-naphthol), were listed as certifiable and then withdrawn about 6 months later, on June 7, 1919. These colors were removed from the list because they produced a skin rash on persons handling them in quantity. The carcinogenic properties of butter yellow are now well known, but no hint of these properties was disclosed until several years after use of that color in food had been abandoned. In 1938, when the new law was passed, there were 15 colors listed as certifiable, all of which had been listed for at least 9 years.

Regulations Under the 1938 Act

When certification of colors for food, drugs, and cosmetics became compulsory, prompt adoption of lists of suitable colors was essential. After discussions with the dye manufacturers and representatives of the food, drug, and cosmetic industries, a number of colors were selected. They were tested chemically and submitted to such tests for toxicity as facilities permitted. Because it was necessary to adopt lists quickly in order to prevent a chaotic situation in the industries, the tests were considerably less than optimum. The chemical information was sometimes incomplete and sometimes, it was later learned, based on erroneous literature. The pharmacological information suffered from lack of data about the chronic toxicity of the dyes. The final step in the selection of colors was a series of hearings at which any interested party was permitted to testify and to cross-examine witnesses.

Following these hearings, regulations listing certifiable colors were adopted. These are substantially the regulations now in force. The colors are separated into three classes:

FD&C colors: Certifiable for use in coloring food, drugs, and cosmetics. These included all the colors that had been listed under the 1906 act.

D&C colors: Certifiable for use in coloring

drugs and cosmetics, but not in food. These colors were all new to certification.

Ext D&C colors: Certifiable for use in coloring externally applied drugs and cosmetics, but not for food or for drugs or cosmetics applied to a mucous membrane. These also were colors not previously certifiable.

No colors are certified for use in the area of the eye, since no drugs or cosmetics intended for use in this area may be colored with any coal-tar color.

Shortly after the first regulations under the 1938 act were adopted, three additional colors were added to the FD&C list. Two of these were oil-soluble dyes, FD&C Orange No. 2 and FD&C Red No. 32, used principally in the external coloring of oranges. The other was FD&C Yellow No. 2, the potassium salt of 2,4-dinitro-1-naphthol-7-sulfonic acid. (FD&C Yellow No. 1 is the corresponding sodium salt.) Oddly enough, no batch of FD&C Yellow No. 2 has ever been certified.

Later actions added one color to the list of Ext D&C dyes and placed one of the original D&C colors on the FD&C list as FD&C Violet No. 1.

The preparation and adoption of the coal-tar color regulations was a remarkable feat of cooperation between Government and industry. Both parties combined in the effort to make the regulations practical for the industry and effective for protection of the public. It is a tribute to their success that no basic changes in the regulations have been made except those dependent on information not available in 1938.

Recent Activities

It was realized in 1938 that the lack of data about chronic toxicity of coal-tar colors was a matter that required attention. Some studies were conducted, but the imminence of war and the war itself made it impossible properly to attack the problem until several years later.

Research in development of improved methods of chemical analysis was continued, but this work also was largely suspended during the war years. After the war, the availability of new apparatus, particularly spectrophotometric instruments, made progress much more rapid and results more certain.

Certification of FD&C Yellow No. 6

Specifications and procedures for FD&C Yellow No. 6 illustrate the requirements that colors must meet and the tests they must undergo in order to be certified.

General Specifications for All FD&C Colors

"No batch of a straight color listed . . . shall be certified under these regulations unless—

"(a) It is free from all impurities (other than those named in paragraph (b) or in the specifications set forth . . . for such color) to the extent that such impurities can be avoided by good manufacturing practice.

"(b) It conforms to the following specification:
(1) In the case of a straight color listed in section 9.3 [i. e., an FD&C color]—

Lead (as Pb), not more than 0.001 percent.

Arsenic (as As_2O_3), not more than 0.00014 percent.

Heavy metals (except Pb and As) (by precipitation as sulfides), not more than trace."

Specific Requirements for FD&C Yellow No. 6

FD&C Yellow No. 6 is described as a "disodium salt of 1-*p*-sulfophenylazo-2-naphthol-6-sulfonic acid." It must meet the following requirements:

Volatile matter (at 135° C.), not more than 10.0 percent.

Water insoluble matter, not more than 0.5 percent.

Ether extracts, not more than 0.2 percent.

Chlorides and sulfates of sodium, not more than 5.0 percent.

Mixed oxides, not more than 1.0 percent.

Subsidiary dyes, not more than 5.0 percent.

Pure dye (as determined by titration with titanium trichloride), not less than 85.0 percent.

Analytical Determinations

Determination of total dye in the sample by titration with titanium trichloride, which quantitatively reduces the azo group.

Determination of the identity and quantity of dye by spectrophotometric procedures. Spectra in the visible, infrared, and ultraviolet regions are obtained and compared with spectra obtained from standard samples prepared in the FDA laboratories.

Determination of sodium chloride, sodium sulfate, insoluble matter, and volatile matter.

Determination of subsidiary dyes. Sodium salts of the following may be present: 1-phenylazo-2-naphthol-6-sulfonic acid, present if the sulfanilic acid used as an intermediate contains any aniline; 1-*p*-sulfophenylazo-2-naphthol-3,6-disulfonic acid and 1-*p*-sulfophenylazo-2-naphthol-6,8-disulfonic acid, present to some extent in all samples since it is almost impossible to prepare 2-naphthol-6-sulfonic acid entirely free from the disulfonated compounds; 1-(4-sulfophenylazo)-2-naphthol, present because some betanaphthol may be present in the sulfonated compound.

Determination of ether extracts, a measure of any organic tars or other ether soluble substances that may remain in the intermediates.

Determination of uncombined intermediates, present because of incomplete diazotization or coupling. Sulfanilic acid and 2-naphthol-6-sulfonic acid are the intermediates used for FD&C Yellow No. 6.

Determination of mixed oxides (iron, aluminum, etc.) that may be present. These usually get into the product because the processing equipment is attacked by reagents used in preparation of the dye.

Determination of lead and arsenic, usually present in the acids used in the sulfonation and nitration reactions carried out in the preparation of the intermediates.

Determination of heavy metals—copper, bismuth, tin, antimony, cadmium, and mercury. These also get into the dyes from processing equipment.

In addition, to meet the "good manufacturing practice" requirement in the general specifications, it must not contain more than traces of uncombined intermediates or of phenylazo-2-naphthol-6-sulfonic acid. Experience of many years has shown that it is practical to obtain almost complete removal of these impurities.

Certification or Rejection

If the sample is found to meet all the specifications, including the "good manufacturing practice" requirements, a certificate covering the batch is issued. If the sample fails to meet any one of the specifications, the batch is rejected.

Recent chemical investigations have shown that some of the colors do not have the exact composition or structure ascribed by earlier work. This information will probably not affect the status of the colors as certifiable, but it is of fundamental importance in establishing methods of analysis and standards that batches of the colors must meet in order to be certified.

Methods of analysis for coal-tar colors are a part of the program of the Association of Official Agricultural Chemists, and the results of the FDA's chemical investigations are usually published in the journal of that association. A mimeographed publication containing the methods of analysis used in the color-certification laboratory is also available.

Some of the recent pharmacological investigations have produced surprising results. Three colors, FD&C Orange No. 1, FD&C Red No. 32, and FD&C Orange No. 2, have been found to be considerably more toxic than was disclosed by earlier tests. These dyes act as gastrointestinal irritants. The toxicity of FD&C Orange No. 1 and of FD&C Red No. 32 has been confirmed by illness following ingestion of candy or popcorn containing these colors. In each case, the products contained very much more color than is customarily used.

As a result of the new tests, the Secretary of Health, Education, and Welfare issued a regulation removing the three colors from the lists of colors certifiable for use in food and drugs in November 1955. This regulation is now in effect with the exception of its application to FD&C Red No. 32 for coloring the outer skin of oranges. A stay issued by the Fifth Circuit Court of Appeals requires the continued certification of sufficient color for that use until the court has finally disposed of a petition to review the entire regulation. The colors were retained as certifiable for use in externally applied preparations since evidence is available to show that they are safe for such use.

Legal action against excessive use of certified colors is not authorized under the Federal Food, Drug, and Cosmetic Act. Section 406 (b) reads: "The Secretary shall promulgate regulations providing for the listing of coal-tar colors which are harmless and suitable for use in food, and for the certification of batches of such colors with or without harmless dilu-

ents." Sections 504 and 604 have almost identical wording with respect to colors for drugs and cosmetics.

The meaning of the word "harmless" is the cause of difficulty. The Food and Drug Administration believes the word to mean that the colors must be harmless per se, that is, without regard to the amounts of colors that would or could be consumed by the individual. This means, of course, that the colors must be without detectable physiological effect except that of inert or nonnutritive substances. The absolute harmlessness of any substance is virtually impossible to demonstrate.

The production of certified colors has increased steadily with the general expansion of the national economy. In 1941, about 2¼ million pounds of coal-tar colors were certified in 3,677 batches. In 1955, the amount was more than 5 million pounds in 4,675 batches. These figures include not only the highly concentrated "straight" colors, but also mixtures of the colors with various diluents, such as salt, sugar, or water. Such mixtures, which may contain two or more colors as well as diluents, are usually used instead of the straight colors in coloring food.

Certification of the 4,675 batches of coal-tar colors in 1955 required more than 25,000 analytical determinations, or about 100 per working day. An example of the certification requirements and procedures is given on page 584.

There have been very few regulatory actions against products containing uncertified colors in recent years. The requirements of the law are well known, and the food, drug, and cosmetic manufacturers generally make every effort to comply. In a few instances, products made in other countries have been denied entry into this country because they were found to contain uncertified colors.

Investigation of the production procedures used by the manufacturers of straight colors and mixtures has shown that few have failed to follow the regulations in every particular.

Program Needs

By law, the listing and certification of coal-tar colors is performed only upon payment of such fees as may be necessary to provide, main-

tain, and equip an adequate service for such purposes. Hence, the certification program is not handicapped by a lack of funds. But as demands for services increase, it is necessary to adjust facilities and personnel accordingly. Since the present program is the maximum that

can be contained in the available laboratory and office space, relocation of the facilities is a matter for immediate attention. Recruiting and holding an adequate supply of personnel is a chronic problem, but at the moment at least all assigned positions are filled.

Food (and Drugs) for Thought

You may use the form on the inside back cover to subscribe to *Public Health Reports*.

Each month this journal carries reports of events in health practice and scientific research, from details of laboratory studies to broad reviews of trends. It is a market for ideas and a record of basic studies.

Changing the Priorities in Public Health

Stream Enrichment and Microbiota

Diagnosis of Psittacosis in Parakeets

Drugs and Medical Devices

By ALBERT H. HOLLAND, Jr., M.D.

The medical program of the Food and Drug Administration is concerned primarily with assuring the safety of drugs and medical devices to protect public health as provided by law. Secondly, it advises the Commissioner's Office and the other scientific and administrative programs of FDA on medical matters.

The major elements of the medical program may be characterized by the words "Stop, look, and listen." As provided by law and regulation, FDA attempts to stop the violator; it looks at new drug applications and medical investigative data; and it listens to what is going on generally in the drug and device industries so that proper preventive or remedial action can be instituted when necessary.

The objective of the Federal Food, Drug, and Cosmetic Act with respect to drugs is to assure the safety, quality, purity, and identity of all drug products in interstate commerce, thereby fulfilling the ultimate objective of protecting the public health. Drugs imported into this country are subject to the same scrutiny and legal requirements.

Dr. Holland is medical director of the Food and Drug Administration. When appointed to this position in 1954, he was medical director of the Armour Laboratories. He has also served as director of the Office of Research and Medicine, Oak Ridge Operations of the Atomic Energy Commission, and as medical officer assigned to the Manhattan Engineering District project at Oak Ridge.

Actually, all aspects of the medical program are geared to one key word—safety. Purity, quality, identity, and labeling, including therapeutic claims, must all measure up to the requirements imposed by the reasonable application of the concept of safety.

It is perhaps of significance that the original Federal food and drug legislation, the Food and Drugs Act of 1906, was conceived and enacted by the Congress at the behest of a physician, Dr. Harvey W. Wiley, who was at the time chief chemist of the Department of Agriculture. The Food and Drug Administration, therefore, has a medical heritage of which it can well be proud and which clearly establishes it, both historically and for the future, as a public health agency of government.

Responsibilities and Functions

The New Drug Branch of the Division of Medicine bears the responsibility for reviewing new drug applications in detail, interpreting the investigative data, and permitting or denying the introduction of a new drug into interstate commerce. Its task is one that requires the exercise of the highest degree of good judgment and medical acumen. It is one thing to assess the investigative results obtained by a few medical experts in carefully selected patients under controlled conditions; it is quite another to extrapolate that data to nationwide use—perhaps indiscriminate use by some physicians or by the public if the drug is one that may legally be sold without a prescription.

The Veterinary Medical Branch has the same purview of new drugs for animal use as does

the New Drug Branch of drugs for human use. In addition, it has a regulatory or enforcement function for all veterinary medicinals, be they old or new drugs.

The Drug and Device Branch works primarily to obtain compliance with, and enforcement of, the law with respect to the safety and adequacy of labeling of drugs and medical devices in interstate commerce. But to apply scientific judgment in a court of law entails peculiar difficulties. Medicine at its best is still far from being an exact science. Biological variation and biological response in the subject, as well as variations of interpretation by the investigator, frequently preclude satisfactory quantitation. The art and the science are not always clearly distinguishable, and opinion and fact are not always readily separable. That this is true becomes evident when FDA resorts to legal measures to achieve enforcement and control. Honest admission of uncertainty by a scientific witness may too often strike a jury as "reasonable doubt" as to the guilt of the defendant. To reach a bona fide medical conclusion is one thing; to prove it beyond reasonable doubt in a court of law is quite another.

One important aspect of assuring the safety of drugs and devices is preventing misbranding. The legal definition of misbranding has many facets. Those readers who are responsible for enforcing parallel State laws know them well; for others, a few basic concepts that illustrate the philosophy of the law may be mentioned here.

A drug or device is deemed to be misbranded:

1. If its labeling is false or misleading in any particular.
2. If, in finished or bulk package form, it fails to bear a label giving the name and place of business of the manufacturer, packer, or distributor, and an accurate statement of contents.
3. If any word, statement, or other information required under the authority of the act to appear on the label or labeling is not displayed with such conspicuousness and in such terms as to make it likely to be read and understood by the ordinary individual under customary conditions of purchase and use.
4. Unless its labeling bears adequate direc-

FDA inspector in the stock-room of a drug factory producing injectables. The bulk solutions are examined for undissolved particles before they are packed and sealed in ampules.

tions for use, adequate warnings against use in pathological conditions or by children when such use may be dangerous to health, and adequate warnings against unsafe dosage or methods or duration of administration or application. This does not, however, apply to household chemicals except those specifically covered in the Federal Caustic Poison Act. Under the Federal Food, Drug, and Cosmetic Act all drugs are subject to this requirement.

From the foregoing it is apparent that the food and drug legislation is designed to inform and protect the user of drugs or devices whether he be a physician or a patient. While the law is designed to protect, it is well also to recognize its limitations. The Federal Food, Drug, and Cosmetic Act applies only to the content and labeling of products shipped in interstate commerce. The Food and Drug Ad-

ministration, therefore, is not responsible for advertising, which is regulated by the Federal Trade Commission. FDA does, however, cooperate with the Federal Trade Commission, usually by making, at its request, laboratory studies of products in question. In addition, FDA provides the medical support for fraud cases brought by the Post Office Department.

Techniques of Control

To carry out the provisions of the law, the Food and Drug Administration employs many techniques. It maintains a nationwide inspection staff of approximately 250 men who devote their time to food and drug inspections in all channels of distribution from manufacturer to the ultimate distributor. It also maintains a series of field laboratories where samples of drugs are analyzed.

FDA is in continuing contact with all segments of the drug trade and with the medical profession. It is now in the process of enlarging its file of reports on injuries from drugs and household chemicals. The Research and Reference Branch of the Division of Medicine is interested in all types of drug injuries or suspected injuries whether they culminate in death, blood dyscrasias, sensitivity reactions, or other toxic manifestations. Often it is only by slowly and painfully piecing together the puzzle that a significant pattern is found. FDA must and does maintain constant surveillance of the medical literature and medical reports, as well as its incoming mail. Recently, the medical staff has had occasion to work with those interested in the operation of poison control centers throughout the country.

Public health officials can be of great assistance to the Food and Drug Administration in providing the protection which the law intends and which so many people take for granted. For example, health officers often are in a position to supply information about the business of a cancer quack, about medical devices which may not meet the requirements of the law, or about injuries caused by drugs.

About a cancer quack, FDA needs to know such things as how he is operating his racket, the names of his patients, when his patients die, and findings of autopsies.

About medical devices, FDA needs to know: When and where are they sold and used and by whom? What claims are made for them? Is an interstate shipment involved? Is there label copy or descriptive literature available?

An immediate report of a drug injury or a suspected injury containing all the facts available is of utmost importance. What was the drug used? How was it administered? By whom? What dosage was employed? What is the name of the manufacturer? of the patient? of the physician? Too frequently FDA does not hear of adverse experiences with drugs until months after they occur, when the details crucial to intelligent interpretation have been forgotten or are no longer available.

To protect the public against adulterated or misbranded medicines, as provided by law, the Food and Drug Administration needs the assistance of all persons who are concerned with health, whether they be physicians in private practice, officials of government agencies, or members of the drug and device industries. It also needs the understanding and cooperation of an informed public.

Assuring the Safety of New Drugs

By RALPH G. SMITH, M.D.

Before the Federal Food, Drug, and Cosmetic Act was passed in 1938, new drugs could be introduced into interstate commerce without approval from any Federal agency or without consultation with any Federal agency. The distributor had no responsibility under Federal law for the safety of the new product. The marketing of drugs was subject to the provisions of the Food and Drugs Act of 1906, which dealt with adulteration and misbranding of drugs only after a drug was in the channels of distribution. The 1906 act did not deal directly with safety of drugs.

Although many of the drugs on the market in 1938 were satisfactory, further control was needed. With the advancement of pharmaceutical chemistry and the expansion of pharmacological research and screening procedures, particularly by industry, many new products were becoming available for drug use.

Most of the new products were synthetic compounds, but a few were purified active agents of old galenical drugs or derivatives of these agents. Many had specific pharmacological actions and were, accordingly, of interest from the therapeutic standpoint. In addition to useful therapeutic actions, however, some of the new products possessed potentialities for harmful effects. As with all new compounds, the

nature of these effects and the margin of safety could be revealed only by appropriate study. Some control, additional to the judgment of the distributor, on the safety of the drug seemed to be in the public interest.

Accordingly, early drafts of the Federal Food, Drug, and Cosmetic Act included a provision that a drug was misbranded if it was unsafe for the use suggested in its labeling. By a coincidence, the well-known elixir of sulfanilamide disaster, which occurred while the bill was under consideration, convinced the Congress of the necessity for new drug provisions in the law. As a result of a new toxic vehicle or solvent in the sulfanilamide product, more than 100 deaths occurred within a very short time and before adequate warnings or removal of the drug from the market was possible.

For Effective Application

The new drug section of the 1938 act prohibits the distribution in interstate commerce of a new drug until an application for it is effective. In order for the application to become effective, adequate evidence that the drug is safe when used according to the labeling furnished for it must be included in the application.

Applications for new drugs are received and reviewed by the New Drug Branch of the Division of Medicine, Food and Drug Administration. The review procedure calls for the assistance of other FDA technical divisions whenever indicated. The advice of original investigators or of other organizations or of experts outside the FDA may be sought in specific instances.

Dr. Smith is chief, New Drug Branch, Division of Medicine, Food and Drug Administration.

Since products which are not new drugs may still be introduced into interstate commerce without any legal formalities or even notification to the Food and Drug Administration, it is of obvious importance to decide whether a drug is new. In many instances the answer is apparent, but in certain cases some definite criterion is necessary for a decision.

A definition of a new drug is included in the 1938 act. In simple terms, a new drug is a drug which is not generally recognized, by experts qualified to evaluate the safety of drugs, as safe when used as directed in its labeling.

A yardstick is even more necessary to determine when a product ceases to have the status of a new drug. This point is also covered by definition in the act. Even though sufficient evidence may be available from investigative studies to show that a drug is safe for use, the drug continues to be considered as a new drug until it has been used to a material extent or for a material time under the conditions set forth in its labeling.

Continuance of a product in new drug status for a considerable period of time is significant in two ways. It means that the product must not only be indicated as safe by investigative studies but that it must stand the test of use under ordinary marketing conditions before it loses its new drug status and is freed from the restrictions which the status entails. It also means that any company wishing to market the drug must also obtain an effective new drug application even though the drug is already being distributed by the company holding the original effective application. Each additional application must include adequate evidence of the drug's safety.

The definition of a new drug is further interpreted by regulation. Food and drug regulations point out that a product may be considered new not only when it contains a new active ingredient but also when it includes a new excipient, coating, menstruum, carrier, or other component. A new combination of two or more old drugs or a change in the usual proportions of the ingredients in an old combination may cause the product to be considered a new drug. A new use, a new dosage schedule, or a new route of administration for a commonly recognized drug may also result in a

new drug within the meaning of the definition.

In many instances little difficulty arises in deciding that a drug is new, but there are also numerous cases in which a decision can be reached only by careful consideration of all available facts. It must be determined whether the changes from recognized formulations or therapeutic procedures are sufficiently significant to raise a question of safety. An honest difference of opinion on the new drug status of a product occasionally arises between the manufacturer and the Food and Drug Administration. The difference may be resolved in either direction on consultation. Generally, however, the advice of the Food and Drug Administration is accepted although the Federal courts have the jurisdiction for deciding the matter.

Although the new drug section of the 1938 act is applicable to most new drugs, there are certain exemptions. Drugs which were distributed under essentially the same labeling prior to the effective date of the act (June 25, 1938) are excluded by definition even though they may not be generally recognized as safe. Vaccines, serums, toxins, antitoxins, and most blood products which are licensed under the Biologics Control Law enforced by the Public Health Service are exempt by regulation from the new drug procedure. Likewise, the five antibiotics, penicillin, streptomycin, aureomycin, chloramphenicol, and bacitracin, and derivatives of those antibiotics that are subject to certification by the Food and Drug Administration are exempt by law from the new drug section of the act.

For Safe Use of a Drug

The application should contain detailed reports of well-planned animal and clinical experiments. Data of the following type are important: the age, sex, and pathological condition of the subject; the dose of the drug used; the frequency and duration of administration; the results of clinical and laboratory examinations; the nature and incidence of adverse effects; and the therapeutic results.

Animal studies are usually considered necessary, particularly if the product contains an ingredient new to therapeutics. These studies demonstrate the nature of the pharmacological action of the drugs and also the type of effect

obtained by overdosage. Acute toxicity experiments yield a measure of the therapeutic index or safety margin. Subacute and chronic experiments with hematological examinations and histopathological studies give additional information in this connection. The clinical investigator may be expected to demand reports of such studies before he uses the drug on patients.

The type of investigation, both animal and clinical, should be determined by the proposed use of the drug with respect to method and duration of administration. A drug which is recommended for the treatment of chronic conditions such as arthritis, epilepsy, or parkinsonism will require animal toxicity studies of prolonged duration. Shorter toxicity studies would suffice for a drug such as a general anesthetic for use in a single administration. Likewise, a chemotherapeutic agent indicated for the treatment of an acute infection would be used only for a few days to a week or so and, consequently, would not require prolonged animal toxicity studies. Drugs for topical application, such as ointments, lotions, and topical anesthetics and antiseptics, should include studies on their potentiality to produce primary irritation and sensitization. Information on the degree of absorption from skin or mucous membranes may also be indicated when there is a question of systemic toxicity.

The application must also include a full list of the components which go into the preparation of the drug even if they do not appear in the final product. Their disclosure is of interest from the standpoint of their possible retention as impurities in the finished preparation. A complete quantitative statement of the composition of the drug is an obvious requirement. A description of the manufacturing methods and control procedures used in producing the new drug is required to provide the assurance that a preparation of definite specifications with respect to identity, strength, quality, and purity will be produced.

A sample of the drug may be required with the application, and completed market packages are required as they become available. Finally, copies of the proposed labeling must be furnished as part of the application since the safety of the drug must be evaluated on the

basis of all the conditions under which it is recommended for use.

If the New Drug Branch is satisfied that the drug will be safe when used as proposed, the application is allowed to become effective, which means that permission is granted for distribution of the new drug in interstate commerce.

Marketing New Drugs

Since a drug retains its new drug status for some time after initial distribution, its use under actual marketing conditions is a further test of safety and usually a more severe test than the carefully supervised investigative studies. The general distribution of a drug which appears safe on the basis of investigative studies may be followed by reports of effects of an unexpected nature or of a higher incidence of side effects than occurred in preliminary use. Provision is made in the law to suspend an effective application under these conditions if the hazards of use are considered sufficiently serious. Applications have been suspended for this reason.

Much experience has been gained in the new drug section in the 18 years since the act was passed. As of January 31, 1956, applications for new drugs numbered 10,350, and 7,365 became effective. These figures include applications for veterinary medicaments, which account for approximately 18 percent of the applications submitted since July 1, 1954.

The 3,000 applications which did not become effective fall largely into three classes. Approximately 1,800 were incomplete. Some 500 were withdrawn, usually as a result of objections based on inadequate showing of safety. About 600 were not considered to be new drugs and, accordingly, did not require an effective application for marketing. Action is still pending on 100 applications.

The fact that 7,365 applications became effective does not mean that 7,365 new chemical compounds were introduced as therapeutic agents during the 18-year period.

Numerous firms may submit an application for the same drug. Separate applications may be submitted for various dosage forms of the same drug, such as oral preparations and injections. Or, the new drug in combination with a variety of old drugs may account for a num-

ber of applications. Although each application does not represent an entirely new chemical substance, it does represent a distinct effort by both the manufacturer and the Food and Drug Administration to assure that the consumer can use the product with safety.

The distributor, in addition to following the marketing experience of the new drug, frequently has occasion to change the provisions of his effective application. He may find it advisable to modify certain procedures in the manufacturing process, to make changes in the formulation, or to revise the labeling. A revision of the labeling may involve the inclusion of a warning statement or an additional indication for use of the drug, or it may provide for the product to be distributed under the label of another company.

Changes in the effective application may be made by submitting supplements, which are processed in the same manner as the original application. This procedure is in effect as long as the product remains a new drug. In view of the large number of effective applications on file, it is not surprising that the current number of supplementary applications and related correspondence exceeds 4,500 pieces a year.

It is probable that the safety of the new drug would be achieved in most instances without governmental control. The control procedure, however, is justified if it prevents even rare instances of injury by the distribution of drugs. The necessity of additional safeguards was felt in 1938 when the new drug section of the act was introduced. Since that time, the necessity has become still more imperative because of an even more rapid increase in the production of new products with a potentiality for drug use.

The Calculated Risk

The New Drug Branch has seen the quality of new drug applications improve during the past few years. A concept of adequate investigation of a new drug has been gradually developed by the Food and Drug Administration and by the pharmaceutical companies so that today new drugs are being investigated more thoroughly than ever before. Greater precautions are being taken by the adoption of stricter manufacturing

control procedures to assure the marketing of products of specified potency and adequate purity. The new drug procedure has been instrumental in promoting these achievements.

Such safeguards should justify the physician's reliance on the declared potency and purity of the product he administers or prescribes and should strengthen the patient's trust in the safety of the remedy. In spite of this, certain facts should be kept in mind.

Safety is a relative term. Probably no two drugs are safe to the same degree. The wide variation in individual tolerance to drugs is recognized. Consequently, a wide margin between the effective dose and the toxic dose is essential if the drug is to be safe for the vast majority of potential consumers. The wide margin of safety is particularly necessary for remedies which are not life saving or which are used for conditions amenable to treatment by other methods or drugs that are relatively safe. In contrast, applications may be allowed to become effective for drugs that are known to be dangerous and for which the safety margin is critical. Granting of these applications is considered to be justified only when the drugs are useful as a life-saving or life-prolonging measure in conditions for which there is no safer efficacious remedy.

In the use of drugs which involve a calculated risk, their potentialities for harm are decreased if the physician recognizes that the potentialities exist and takes all possible precautions against adverse occurrences. Usually, care is taken in the labeling of a drug to outline optimal dosage ranges from the standpoint of both efficacy and safety and to include necessary warnings, precautions, and contraindications for its use. Careful labeling can serve its purpose only if it is read. With the introduction of so many new drugs, the physician can become familiar with only a few. Those which he selects, however, should be studied with particular care by taking advantage of all information imparted in the labeling instructions and in the published literature. The physician can contribute significantly to the safety of a new drug by reporting to the Food and Drug Administration, or by publication, any adverse reactions he observes in his practice.

Certification of Antibiotics

By HENRY WELCH, Ph.D.

It is generally agreed that little if any good is accomplished by wars. Penicillin perhaps is the exception, for its development, rapid availability, and wide use stemmed from the great need for the drug in World War II. Similarly, the antibiotics certification program got its initial impetus because of our entrance into this worldwide conflict.

In 1941 there was insufficient penicillin in the United States to treat a single case, and in 1942 probably not enough to treat a hundred cases. However, by September 1943 there was sufficient penicillin to satisfy the early demands of the Armed Forces of this country and those of our allies.

It was during September 1943, at the request of the Armed Forces and the War Production Board of the United States, that the Food and Drug Administration undertook the testing of each lot of penicillin produced, for potency, sterility, toxicity, pyrogenicity, pH, and moisture content. On the basis of the results obtained by these tests, the lot was either accepted or rejected.

By June 1945 there was sufficient penicillin to satisfy not only the Armed Forces but a great civilian demand as well, and there was an ap-

parent need for a method of control for this important therapeutic agent. On July 6, 1945, the Federal Food, Drug, and Cosmetic Act was amended to require the certification of batches of drugs composed wholly or partly of any kind of penicillin. The Federal Security Administrator, in accordance with the provisions of this amendment, promulgated regulations providing such standards of identity, strength, quality, and purity as would insure the safety and efficacy of penicillin and penicillin preparations.

Under the law, each manufacturer, before distributing a batch of penicillin in interstate commerce, must submit samples of the batch to the Food and Drug Administration for examination and must obtain a certificate showing that it complies with applicable regulations. Each product proposed for certification to the Food and Drug Administration must be shown to be safe and efficacious, this proof being based on actual clinical trial.

In 1947 the Federal Food, Drug, and Cosmetic Act was amended to include streptomycin and its derivatives. In 1949 it was further amended to include aureomycin (chlortetracycline), chloramphenicol (chloromycetin), and bacitracin. Tetracycline, being a derivative of aureomycin, is also certified by the Government.

There have been no amendments to the act since 1949 to require the certification of antibiotics developed since that time. Therefore, all other currently available antibiotics are subject only to the general provisions of the act, unless they are added to one of the antibiotics for which certification is required.

Growth of the Antibiotics Industry

When penicillin was first produced in the United States, the potency and hence the purity

Dr. Welch is director of the Division of Antibiotics, Food and Drug Administration. Since its beginning in 1943, he has been in charge of the FDA's antibiotics certification program. He is a co-author of the books, Antibiotic Therapy (1951) and Principles and Practices of Antibiotic Therapy (1954); the editor of the Manual of Antibiotics (1954); and the editor in chief of the journals, "Antibiotics and Chemotherapy" and "Antibiotic Medicine."

was quite low. Early assays of this drug indicated average potency ranges from 100 to 200 units per milligram. The purity of penicillin improved rapidly in the first few years of manufacture, and the crude material, consisting of a dark brown, amorphous powder, gradually changed in color and consistency to a light brown, then yellow, and finally, the white crystalline form. Production amounted to only about 29 pounds in 1943.

When penicillin became available for the civilian population in 1945, the purity of the drug had been improved considerably so that the calcium salt, which was the one used to the greatest extent, had a potency on the order of 1,200 units per milligram. The crystalline drug (sodium penicillin), which soon appeared, had a potency of 1,667 units per milligram.

During the war years and for some time thereafter, 20 manufacturers in this country produced practically the entire world's supply of penicillin. Competition as such did not exist. All that was produced was consumed and the price was high. The Army paid as much as \$20 for each 100,000 units. By contrast, in late 1955 the Army purchased penicillin in vials packed in wooden cases for shipment overseas for 5 cents for each 300,000 units; that is, less than 2 cents per 100,000 units. Competition now is extremely keen, and instead of 20 manufacturers of penicillin, there are only 9. In fact, 4 of these 9 account for some 70 percent of the production. In addition to the 9 manufacturers of penicillin, there are 4 others producing antibiotics. These 13 manufacturers are responsible for the great bulk of the world's supply of these important drugs.

Production of penicillin in this country started an industry that today has a capital worth of about \$1 billion. In less than 15 years a number of other antibiotic drugs have found their way into the therapy of infectious diseases. In table 1 are the 24 antibiotics that have been shown to be clinically useful of the 3,000 to 4,000 that have been described in the literature. In addition to these 24, hundreds of others are awaiting tests on the shelves of those manufacturers still in the antibiotics field.

Changes in production and approximate dollar value of the seven antibiotics that are

² Although isolated from different sources, cathomycin and streptonivicin have been shown to be the same antibiotic.

used to the greatest extent—penicillin, streptomycin, dihydrostreptomycin, and the broad-spectrum antibiotics—are shown in table 2. Only 29 pounds of crude penicillin were produced in 1943, and this amount had a value at the manufacturers' level of about \$3 million. Production increased more than 100 times in 1944. In 1945 the original estimate of 5,000 kg., which was expected to be sufficient to supply the world demand, was exceeded by a considerable amount: Fourteen thousand pounds, or more than 6,000 kg., were produced. Competition in the industry became extremely keen from 1951 on, and although 756,000 pounds were produced in 1953, the dollar value was less than half that of the 636,000 pounds produced in 1951.

The history of the production of streptomycin is not markedly different. The experience in production methods obtained with penicillin resulted in some 3,800 pounds being produced in 1946, the first year that streptomycin was available commercially. This drug, too, when first used was expensive, in the neighborhood of \$15 per gram. The competition in penicillin was re-

flected in the price of streptomycin by 1953, and although 375,000 pounds were produced, 100 times as much as in 1946, the value increased only 3 times.

More than 417,000 pounds of the broad-spectrum drugs were produced in 1953, with an approximate value of \$137 million. In 1954, 410,000 pounds valued at \$150 million were made available.

The broad-spectrum antibiotics and penicillin have uses other than in the prophylaxis and treatment of disease. They are used, for example, in the promotion of animal growth, and in 1954 some 490,000 pounds were produced for feed supplements. The total for all antibiotics in 1954 was some 2,284,000 pounds, with an approximate value at the manufacturers' level of more than \$272 million. According to recent estimates, production was not materially different in 1955.

A large number of antibiotic preparations are now available to the physician in this country. Among those preparations sold in greatest quantity, there are more than 300 available for clinical use. Preparations containing penicillin number 150. There are 38 streptomycin and dihydrostreptomycin preparations, 47 chlortetracycline and tetracycline preparations, 25 oxy-

tetracycline preparations, 15 chloramphenicol preparations, and 27 bacitracin preparations.

Certification Practices and Principles

At the start of penicillin control in 1943, a group of six technicians of the Food and Drug Administration, in collaboration with other governmental agencies, successfully checked for the Armed Forces all penicillin then produced. The apparatus used was hand built and makeshift to meet the requirements of a group of new methods.

As time went on and new antibiotics came into clinical use, the laboratory force was expanded. New and adequate equipment became available, and by 1950 the staff controlling certifiable antibiotics numbered 80. Instead of milligrams of penicillin worth more than its weight in gold, lots containing hundreds of thousands of vials of penicillin were being assayed, and the glass used for packaging cost more than the drug. Assays were performed on a mass scale with automatic equipment (fig. 1), and special reading devices sped up potency determinations and made them more accurate (fig. 2). Electronic equipment for infrared analysis (fig. 3) and for accurate, automatic temperature determinations (fig. 4) simplified considerably the problems of mass assays.

Since its beginning in 1945, the certification program has been self-sustaining. All equipment is purchased from fees paid by the producers of the certifiable antibiotics. In addition, since it is set up on a cost basis, excess fees are returned quarterly to the manufacturers on a pro rata basis.

Under the certification system a producer of a new antibiotic preparation for which certification is required presents to the Food and Drug Administration clinical data demonstrating the safety and efficacy of his proposed product. If the data are found to be satisfactory, a monograph is prepared establishing standards of identity, strength, quality, and purity. Thereafter, samples of each batch produced are forwarded to the Division of Antibiotics for examination, and a certificate is issued on all batches complying with the standards. At the present time some 20,000 batches of antibiotics and their preparations are examined and certified yearly.

Table 2. Antibiotic production in the United States, 1943-55

Year	Antibiotic	Pounds	Approximate value in millions of dollars

Antibiotic preparations destined for export are not required to be certified under the certification system. Such preparations are exempt under section 801 (d) of the Federal Food, Drug, and Cosmetic Act, provided they meet the

specifications of the foreign buyer, are not in violation of the laws of the country to which they are to be shipped, and are marked clearly for export. The buyer of the foreign country must require that the certifiable drugs pur-

chased meet United States Government standards if he wishes to obtain certified material. If he does this, the preparations for export must be sampled, tested, and certified before shipment. Consequently, some of the United States producers certify all of their preparations whether destined for the domestic or export market.

Since July 1945, nearly 300 companies have used the certification services. During this period of approximately 10 years, 150,000 batches of various preparations of penicillin, streptomycin, dihydrostreptomycin, chlortetracycline, tetracycline, chloramphenicol, and bacitracin have been examined. Taking the usual daily dose of these drugs to be 300,000 units for penicillin, 60,000 units for bacitracin, and 1 gram each for streptomycin, dihydrostreptomycin, chlortetracycline, chloramphenicol, and tetracycline, the quantity of these drugs examined represents approximately 7 billion daily doses. The average cost paid by the producers for

certification of each daily dose was 7/100 of a cent. Over 1,000 batches have been either rejected by FDA or withdrawn by the producer because they were substandard. These substandard batches which were prevented from reaching the consumer represent more than 70 million daily doses.

During the past 5 years, the Administrator of the Federal Security Agency, and later the Secretary of the Department of Health, Education, and Welfare, has found that certification of the antibiotic preparations in the list on page 599 is not necessary to insure safety and efficacy. These preparations are now exempt from certification.

The Impact of Antibiotics

Through use of antibiotics the spectrum of amenable diseases has widened almost yearly. Either completely or partially controlled by the seven antibiotics previously mentioned are

pneumococcal and streptococcal infections, meningococcal and gonococcal infections, staphylococcal infections, syphilis, yaws, pinta, bejel, Weil's disease, relapsing fever, tropical ulcer, Vincent's angina, and many surgical, urinary, and intestinal tract infections; amebiasis, brucellosis, plague, tularemia, and tuberculosis; and diseases due to certain large viruses and rickettsiae, including primary atypical pneumonia, psittacosis, lymphogranuloma venereum, trachoma, Rocky Mountain spotted fever, epidemic and endemic typhus, scrub typhus, and Q fever. Also largely under control are granuloma inguinale, chancroid, Carrion's disease, pertussis, diphtheria, influenzal meningitis, anthrax, actinomycosis, trichomonas vaginalis vaginitis, and rat bite fever. In addition to use against these specific infections, these antibiotics have found wide use in ophthalmology and in oral surgery and dentistry.

This is indeed an imposing list. However, a second line of defense against a variety of infections is also available. Tyrothricin, bacitracin, polymyxin, neomycin, viomycin, erythromycin, carbomycin, and fumagillin all have a place in the physician's armamentarium. These often prove to be successful where the others fail. Furthermore, antibiotics just becoming available may add new ammunition in the war against infectious diseases.

I think it may be safely said that the antibiotic preparations are used as prescription drugs more frequently in treating serious and crippling diseases than any other drug or class of drugs now available. It has been conservatively estimated that in dollars spent for prescription drugs in recent years, 40 percent of all prescriptions drugs sold include one or more antibiotics.

Thus it is obvious that these drugs are of the greatest importance to the public health and that they deserve a special form of control, such as that established by the certification system. The principle on which certification of these drugs is based appears to be sound; that is, they must be certified because of (a) their great importance to the public health, (b) their use in serious and crippling diseases, (c) the security of a double check on their safety and efficacy given the practicing physician and his patients, and (d) their production by biological means, which may result in vagaries in manufacture and assay. Furthermore, the manufacturer is protected adequately from restrictive or paternalistic control by the principle that an antibiotic shall be exempt from certification when the Secretary of the Department of Health, Education, and Welfare feels that it is no longer in the interest of the public health to continue certification.

Certification of Insulin

By R. LORIMER GRANT, Ph.D.

Correct dosage is probably more critical for insulin than for any other drug. Most persons with diabetes must take insulin every day, usually injecting it themselves. A dose that is too small may lead to diabetic coma and even death; an overdose may lower the blood sugar to a level that results in an insulin shock. There are about one million known diabetics in the United States today.

These facts explain the public health importance of the Food and Drug Administration's insulin certification program, which is designed to insure, to the extent possible, that every batch of the drug will be safe and effective when used according to directions.

Insulin was the first drug to be certified by the Food and Drug Administration. Certification was not a new procedure—it had been applied to coal-tar colors for many years—but its application to drugs was new when Congress enacted the insulin amendment in December 1941. This amendment prohibits distribution of any batch of an insulin-containing drug until a certificate has been issued stating that the batch is safe and effective.

History of Insulin Control

The need for special control for insulin by the Food and Drug Administration arose from

Dr. Grant, a pharmacologist, is chief of the Insulin Branch, Division of Pharmacology, Food and Drug Administration.

the expiration, on December 23, 1941, of one of the insulin patents. Until then, the manufacture of insulin in the United States was regulated by the Insulin Committee of the University of Toronto. Banting and Best had given the patent rights of their discovery to the university, and the university's Board of Governors had then taken out the first insulin patents and set up the Insulin Committee to administer them. The privilege of using these patents, and others subsequently administered by the Insulin Committee, was granted to several manufacturers under licensing agreements.

The purpose of the licensing agreements was to make available insulin-containing drugs of uniform and dependable potency at a minimum cost to the user. The potency of each lot of insulin was established on the basis of biological assay in two independent laboratories. The manufacturer was required to make his own assay of a lot and then to submit a sample of the lot to the insulin control laboratory in Toronto, where a second assay was made. As a further check on uniformity of product, the manufacturer was also required to send to the insulin laboratory samples from every batch of finished drug made from a lot of insulin.

The control of potency afforded by these procedures was commendable, and it was appreciated by all governmental agencies concerned with the safety of drugs. In fact, prior to 1941 the Food and Drug Administration did not have facilities for making a reliable assay of insulin potency because these drugs offered no control problems. Moreover, the Federal law was inadequate to deal with insulin drugs. The only procedure available required collection of a sample from interstate shipment, a

time-consuming assay for potency, and then legal action to prevent further distribution of any drug found to be unsafe. This procedure could result in grave consequences for the consumer.

As the expiration date of the patent approached, several groups, particularly the American Medical Association and the Board of Trustees of the United States Pharmacopeia, sought means to continue the special type of control for insulin that had been provided by the Insulin Committee. E. Fullerton Cook, the director of revision of the pharmacopeia, brought the problem to the attention of the Food and Drug Administration in connection with the drafting of a monograph for insulin injection which was to be admitted to the pharmacopeia after the product patent expired. The Commissioner of Food and Drugs, Walter Campbell, proposed that the pharmacopeia set up an insulin board and establish a laboratory for the testing of the drugs prior to distribution. This plan, similar to that for antianemia preparations, was rejected by the Board of Trustees of the pharmacopeia. Instead, it suggested that the monograph for insulin injection carry a requirement that no lot be released until certified by the Commissioner of Food and Drugs. This proposal was not adopted because it could not be enforced under existing law, but it served to introduce a new idea for Federal control of drugs.

To provide a legal basis for certification, new legislation was needed. Identical bills providing for the certification of drugs composed wholly or partly of insulin were introduced in the House of Representatives on December 16, 1941, and in the Senate on the following day. The bill was passed by the House on December 18 and by the Senate on December 19, and was signed by the President on December 22. This law amended the Food, Drug, and Cosmetic Act of 1938 to require that: (a) all insulin-containing drugs be certified before distribution, (b) regulations be promulgated by the Administrator of the Federal Security Agency providing for this certification on a fee basis, and (c) prior to actual certification of batches, those drugs tested and released by the Insulin Committee be released for distribution.

The Insulin Regulations

The procedure for certification of insulin drugs is described in regulations published in the Federal Register. The original regulations appeared February 6, 1942. These have been amended as new drugs have been added or as experience has dictated.

All the insulin regulations have been drafted in collaboration with the manufacturers of insulin and with the advice of the Insulin Committee of the University of Toronto. They provide for a continuation of the two-assay control of the potency of each lot of insulin and for the examination of samples from every finished batch by both the manufacturer and the Food and Drug Administration. The tests and methods of assay, as well as the standards to be met, are largely those suggested by the manufacturers of insulin. In other words, the industry sets its own standards, and the Food and Drug Administration enforces them.

The regulations require that the manufacturer do the following in order to have a batch of a drug certified:

1. Describe the production facilities and the controls used to maintain identity, strength, quality, and purity of each batch of drug.
2. Submit to the Food and Drug Administration for its approval a sample of the insulin to be used in the batch before he submits a batch for certification. With this sample he must submit a trial dilution of the insulin and the results of his own biological assay of the insulin. He may also send the results of a biological assay made in the laboratory of the Insulin Committee.
3. If the batch is to contain protamine or globin, obtain approval from the Food and Drug Administration of the ingredient to be used.
4. If the batch is to be protamine zinc insulin, globin zinc insulin, isophane insulin, or lente insulin, obtain approval from the Food and Drug Administration of the trial mixture which will serve as a pattern for future batches of the drug.
5. Submit samples and the results of tests of the finished drug to the Food and Drug Administration.

In administering the provisions of the regu-

lations, the Food and Drug Administration must do the following:

1. From time to time, inspect the factories making insulin-containing drugs, with special attention to the facilities, procedures, and controls applied to insulin.

2. Analyze samples submitted in connection with a request for approval, make biological assays to determine potency, review protocols of the manufacturer and of the Insulin Committee's testing laboratory, and notify the manufacturer of approval or refusal to approve the material for use in making batches of an insulin drug. If approval is refused, the Commissioner of Food and Drugs must tell the manufacturer the reasons.

3. Test samples from every finished batch of an insulin drug before issuing a certificate stating that the batch is safe and effective. These tests always include a determination of nitrogen content, which is an indirect measure of potency, and a check on sterility.

Since the manufacturer has usually completed all of his tests before submitting a sample, refusals to approve or certify are rare. Most cases of refusal to approve have involved the trial mixtures of the slow-acting insulins. The samples submitted in these cases failed to meet all the standards established to insure uniformity in the type and duration of action of the drug. An adjustment in the proportions of ingredients has usually produced a mixture that could be approved. Certification was refused for one batch of protamine zinc insulin that was found to be more alkaline than the permitted limit. This condition was evidently caused by traces of the washing solution used to clean the vials. Samples of one batch contained viable organisms, but the manufacturer found the contamination after submitting the sample and did not complete his request for certification.

As a measure of the effectiveness of control by certification, the Food and Drug Administration investigates every complaint concerning a certified drug. No complaint has been found to be due to a contaminated or faulty batch of an insulin-containing drug. All partly used samples that have been found to contain viable organisms appeared to have been contaminated by the user. No complaint of lack

of potency has been substantiated. Recently, some patients ignored the label warning and used protamine zinc insulin which had become granular. Samples of the same batch kept in proper storage had a normal physical appearance. We believe that all certified insulin-containing drugs are safe and effective when they are used according to the directions on the labeling.

Organization of Control

The responsibility for certification of insulin has been delegated by the Commissioner of Food and Drugs to the Division of Pharmacology and specifically to the Insulin Branch of that division. The staff of the Insulin Branch consists of the branch chief, one chemist, two laboratory technicians, and one secretary. Laboratory facilities include one animal room, where the rabbit colony is housed and the bioassays are conducted; one chemical laboratory, where routine tests of samples are made; and the combined laboratory and office of the branch chief. These laboratories are equipped and maintained and the staff of the branch is paid from the fees collected from the manufacturers who use the certification service.

The fees for the different services vary, but the major portion of the income is from the fixed fees for certification of batches of finished products. The fee for a single batch is determined by the number of samples submitted for test. At the present time, the cost to the manufacturer is \$50 for batches containing up to 50,000 vials plus \$10 for each additional 10,000 vials in the batch. Any excess of income from the fixed fees over the cost of maintaining the service is refunded. Some fees depend upon the cost of the services. For services that require the use of the animal colony, most of the fee is attributable to the cost of maintaining the colony. For instance, the present cost of a biological assay for potency is approximately \$1,200, more than half of which is for maintaining the animal colony.

Biological Assay Procedures

The most important test required for the certification of insulin is the biological assay for

potency. The potency may be determined by a number of methods, all of which involve a comparison of the drug being tested with a standard insulin. The methods used by the Food and Drug Administration have been the variations of the rabbit method currently official in the United States Pharmacopeia. The U.S.P. XII method required almost 1,000 determinations of blood sugar and two 5-day work weeks for completion. The test now official (U.S.P. XV) is greatly improved. It can be completed in 1 work week, and the confidence limits of the results can be calculated. It is possible, when the responses of the animals are very uniform, to make only 96 blood sugar determinations for a suitable assay, but the usual number is nearly 300.

As with all biological assays, the reliability of the assay of insulin depends on the extent of variation in response of the animals. To obtain

the best results, unsuitable animals must be discarded from the colony. It is therefore essential to have an animal colony that is used exclusively for the assay of insulin and to maintain it in readiness to assay any sample submitted. A chemical method for determining potency would reduce considerably the cost and probably would increase the precision of the results, but our knowledge of the chemical structure of insulin indicates that some entirely new technique will be needed before we realize this goal.

It may appear that certification, while affording maximum protection for the user of insulin, substantially increases the cost of this essential drug and thereby adds to the burden of the consumer. However, we have calculated that the total fees collected by the Food and Drug Administration for insulin certification since the beginning of the program average less than three-tenths of a cent for each vial certified.

Chart from the Food and Drug Administration

Drug sales reflect advances in biochemistry. Approximately half of the total dollar value of prescriptions written today goes into antibiotics unknown in 1939. The sales of endocrines have grown from \$10 million to more than \$90 million. Antihis-

tamines, unknown in 1939, have sales exceeding \$25 million. Barbiturate sales have more than tripled. Sulfonamides have multiplied eightfold, and vitamin sales have increased about sixfold. Drug consumption as a whole has greatly expanded.

An assessment of the serologic response to poliomyelitis vaccine in children, following passive immunization with gamma globulin, and in tuberculous children.

Poliomyelitis Vaccine Studies

By GORDON C. BROWN, Sc.D., ALAN S. RABSON, M.D.,
and DONALD E. CRAIG, Ph.D.

THE RECENT demonstration of the effectiveness of the Salk poliomyelitis vaccine in actual field trials in children (1) has concentrated interest on active immunization in controlling poliomyelitis. Nevertheless, the use of passive immunization in the form of gamma globulin (2, 3) may be indicated under circumstances requiring rapid protection. Since the action of the immune blood serum is almost immediate, but of short duration, it should be possible to combine this effect with the slower but longer lasting active immunity obtained with the vaccine. Before such passive-active immunization procedures are used, however, information must be obtained that the administration of gamma globulin does not

interfere with artificially acquired active immunity.

Previous reports from the virus laboratory of the University of Michigan (4) have shown that gamma globulin does not prevent naturally acquired subclinical infection in human beings or the subsequent development of type-specific antibodies. Mixtures of antipoliomyelitis serum and virus have previously been reported to have very little antigenic effect in animals (5-8), but this was probably due to the fact that the virus was actually neutralized before inoculation.

Early work with virus and immune blood serum administered separately indicated that monkeys could be immunized in this manner although the techniques utilized were hardly adequate for the quantitative measurements attempted by the authors (9-11). More recently, Bodian (8) has described experiments in monkeys receiving gamma globulin in one leg and live virus in the other leg, and concluded that there was no interference with the antigenicity of the vaccine. Howe (12) found that a formalin-inactivated brain tissue vaccine was antigenic in a small number of humans when gamma globulin was inoculated at another site, but none of his subjects received the vaccine without the blood derivative.

The purpose of this paper is to report the

Dr. Brown is professor of epidemiology and Dr. Craig is a research associate at the virus laboratory, department of epidemiology, University of Michigan School of Public Health. Dr. Rabson is a former epidemic intelligence officer, Communicable Disease Center, Public Health Service, Atlanta, Ga. Their studies were aided by a grant from the National Foundation for Infantile Paralysis and by the assistance and cooperation of Dr. Edna M. Jones, associate physician, Maybury Sanatorium, and of the staff of the Wayne County Training School.

serologic results in children given gamma globulin 3 days prior to the administration of poliomyelitis vaccine, and, in addition, to describe the results of control administrations of the same vaccine to children hospitalized with tuberculosis.

Materials and Methods

During the summer of 1954 a small quantity of poliomyelitis vaccine was made available for research purposes through the courtesy of Dr. Jonas E. Salk. This particular lot of material (lot 309) had in fact been used in some areas for the nationwide field trial in 1954, but only as a third dose in conjunction with other lots. It was also used later in the summer and fall of that year in a separate study of infants and preschool children (13) during which it was discovered that, after this additional time of exposure to the merthiolate preservative, an unfortunate loss of antigenicity had occurred.

For most of the children in the present studies, the poliomyelitis vaccine was administered according to the same schedule used in the 1954 field trial; namely, 3 injections of 1.0 ml. each were given intramuscularly in the left deltoid muscle. The second injection was given 1 week after the first. The third injection was given 5 weeks after the first. A small group of children, however, received only 2 inoculations. The second inoculation was given at an interval of 8 to 10 weeks after the first.

When gamma globulin was used, it was ad-

ministered intramuscularly in the gluteus maximus in quantities of 0.28 ml. per pound of body weight. The globulin was from the same lot (lot 212) used in a previous study (4) in which maximal levels of circulating antibodies were observed in 3 days and persisted for no longer than 3 weeks following this dosage.

Passive-Active Immunization

In June 1954, 27 boys, ranging in age from 8 to 10 years, at the Wayne County Training School, Northville, Mich., volunteered for the study. First, blood specimens were taken, then the boys were weighed and inoculated with gamma globulin as described. Three days later they received the first of 3 injections of vaccine. Blood specimens were taken 2 weeks after the last inoculation, or 7 weeks after the first injection. The serums were separated and stored at 4° C. until tested. Neutralization tests were performed by mixing equal volumes of original serum dilutions of 1:4, 1:8, 1:16, 1:64, 1:256, and 1:1024 with the 3 types—type 1 (Mahoney), type 2 (MEF-1), type 3 (Saukett)—of poliomyelitis virus calibrated to yield 100 tissue culture doses per inoculum as calculated by the 50 percent endpoint method (TCD_{50}). After the virus-serum mixtures had been incubated for 1 hour at room temperature, they were placed in tubes containing cultures of HeLa cells and incubated at 37° C. Appropriate tissue, virus titration, and immune serum controls accompanied each test. Microscopic

Figure 1. Serum antibody titer changes in 27 paired serums taken from Wayne County Training School boys before and after inoculation with gamma globulin and poliomyelitis vaccine.

Figure 2. Serum antibody titer changes before and after poliomyelitis vaccination of 47 tuberculous children in Maybury Sanatorium.

evidence of cytopathogenicity was accepted as lack of neutralization.

The serologic response of the children who had been inoculated with gamma globulin 3 days before the administration of the first dose of poliomyelitis vaccine is shown in figure 1. In this figure the numerals at the bottom represent serum antibody levels before vaccination, and the numerals at the left indicate the titers after vaccination. Thus, any circle below the diagonal line would represent a drop in titer; any circle in the diagonal line of squares would indicate no change in titer, and any circle above the diagonal shows that the antibody titer has increased to the titer indicated on the coordinates. In spite of the small number of children studied, it is readily apparent that there was a marked increase in the serum antibody titer in most subjects as shown by the predominance of circles above the di-

agonal line. The median response in the children with undetectable antibodies prior to immunization was between 16-fold and 64-fold, with the more marked increase being observed against types 1 and 2 virus.

Most of the postvaccine titers of the children with demonstrable serum antibodies before vaccination reached the limit of the dilutions employed, namely 1:1024, and some of the titers would undoubtedly have been higher had the dilutions been extended. The controls for this experiment are represented in the results that follow.

Active Immunization

In June 1954, 85 children hospitalized for tuberculosis in the Maybury Sanatorium of the Detroit City Board of Health at Northville, Mich., were selected for study. These patients

ranged in age from 1 to 12 years with a predominance of children of 1 through 6 years. Most of the children had been nonambulatory for 6 months to a year. Blood specimens were first obtained from all; then vaccine was administered according to two schedules of inoculation.

Forty-seven children received 3 injections of 1 ml. intramuscularly at 0, 1, and 5 weeks, as given to the training school group after gamma globulin injections. Thirty-eight children, however, received only 2 inoculations at an interval of 8 to 10 weeks. Two weeks after the last injection, blood specimens were obtained from all the subjects again, and the serums were filed at 4° C. until tested.

For purposes of clarification, the children receiving 3 inoculations will be classified as belonging to group A and those with only 2 inoculations as group B. Five months after the first inoculation, blood specimens were taken from 21 group A and 25 group B subjects. Ten months after the start of the experiment,

specimens were obtained again from 19 of the children (11 of group A and 8 of group B) who were still in the sanatorium, following which a booster inoculation of vaccine (lot E5721) was given, and blood specimens were taken 3 weeks later. These latter individuals, then, were children who had been studied over a period of approximately 1 year during which time 5 blood specimens had been obtained, before and after primary and secondary inoculations. All serums were tested for neutralizing antibodies, as described previously.

Figure 2 presents the serum antibody changes in the tuberculosis patients in Maybury Sanatorium after they received the primary inoculation of the vaccine. The upper part of the figure portrays the changes in the children who received 3 injections (group A), and the lower half shows the results for the group who received 2 injections. It will be seen that regardless of the serum antibody titer prior to vaccination, most of the subjects responded well. Very few persons failed to respond, and

Figure 3. Group A—Composite results of antibody response to standard virus types after 3 injections of Salk vaccine, lot 309.

Figure 4. Group B—Composite results of antibody response to standard virus types after 2 injections of Salk vaccine, lot 309.

most of the failures are related to the type 3 component of the vaccine.

The data on the 47 children receiving 3 inoculations are reorganized as composite charts in figure 3, illustrating the development of demonstrable antibodies where none could be detected prior to vaccination and also portraying the results in the children who had antibodies before vaccination. In each of the four charts the antibody levels before vaccination are shown on the left, and the levels 2 weeks after vaccination are shown in the right-hand column. Thirty-two of the children were from 1 to 5 years of age, and, with the exception of one 12-year-old, the other 15 were from 6 to 9 years old. Thirteen children in the 1- to 5-year group had no demonstrable antibodies to any type of virus; 6 had antibodies to only 1 type; 9 had antibodies to 2 types, and only 4 had antibodies to all 3 types. Twenty-eight subjects were lacking in demonstrable antibodies to either one, two, or to all three types of virus, and the

60 such instances with the titers obtained after vaccination are shown in the upper left portion of the composite chart (fig. 3). A median antibody titer of 16 was observed. This duplicates exactly the median antibody response to vaccine in the 10 subjects of the 6- to 9-year age groups having 17 instances of no antibodies before vaccination although the younger age group appeared to have fewer antibodies initially. In those individuals with measurable antibodies to a given type of virus, the increase in the 1- to 5-year age group from a median of 64 before vaccination to a median of 1,024 after vaccination is again duplicated exactly in the older group.

Figure 4 represents the composite results of antibody changes in children receiving only 2 injections of vaccine. Thirty of the subjects were from 1 to 5 years of age, and only 8 were from 6 to 12 years old. Eight children in the 1- to 5-year group had no demonstrable antibodies to any type of virus, 6 had antibodies to only

1 type, 11 had antibodies to 2 types, and only 5 to all 3 types. The composite chart shows that, when antibodies were not present before vaccination, the median rise in homologous titers was eightfold. In the 22 children 1 to 5 years old with 43 instances of demonstrable antibodies to virus (upper right of the chart), the median homologous titers changed from 16 before vaccination to 256 after vaccination, a 16-fold increase. The number of children in the 6- to 12-year age group was too small for accurate analysis, but the antibody increases in these few are obvious and of the same order.

As mentioned previously, blood specimens were obtained from 46 subjects in the study 5 months after the first inoculation of vaccine. Neutralization tests with these serums showed a median fall in antibody titer against all 3 types of virus regardless of whether the children had received two or three inoculations. The decrease was most marked in the type 1 antibodies and least in the type 3. The primary response to the latter had been less, however. This progressive decrease in measurable antibody is further emphasized in figure 5, which shows the geometric mean of the antibody levels in a series of 5 serums taken over a period of almost a year in those subjects who received 3 inoculations of vaccine at the times indicated by the first 3 arrows and a subsequent inoculation 10 months after the start of primary immunization, as indicated by the single arrow.

The tests revealed a good primary response to vaccination, followed by the gradual decline over the intervening 10 months to a point only slightly greater than that seen before vaccination. The effect of the secondary inoculation in these children, however, was quite pronounced and might have been numerically greater had the test dilutions been extended

since many serums neutralized 100 TCD₅₀ of virus at the highest dilution employed (1:1024). The titers following the secondary vaccination in all children against all 3 types of virus were much higher than before vaccination, and in many persons the increase ranged from less than 1:4 to greater than 1:1024.

Discussion

The extent of the serologic response in children inoculated with gamma globulin 3 days prior to the first injection of poliomyelitis vaccine proves definitely that this dosage, which is twice that usually administered to humans, does not interfere with the development of active, artificially stimulated antibodies. The titers induced in this study were judged to be more than adequate when compared with the titers obtained following vaccination in the field trial of 1954 and when compared more specifically with titers in tuberculosis patients receiving injections from the identical lot of vaccine, on the same schedule and at the same time. These antibody titers reflect the response to the vaccine itself and not the residual passively acquired antibodies of the gamma globulin since previous studies with identical quantities of the same lot of gamma globulin injected in persons without previous antibody showed that only very low titers of antibody not exceeding 1:4 could be detected and then for a period not more than 3 weeks after injection. Thus, the conclusion is inescapable that poliomyelitis vaccine is capable of inducing the formation of antibodies quite uninfluenced by the presence of circulating artificially acquired antibodies. This observation has importance in view of the possible epidemiological circumstances which might indicate the advisability of a course of passive-active immunization in human beings.

The results of vaccinating patients hospitalized for tuberculosis not only serve to control the above results inasmuch as the lot of vaccine and the schedule of inoculation were the same but also illustrate the immunological response to a virus vaccine in nonambulatory persons infected with a debilitating bacterial disease. The 16-fold response to primary vaccination regardless of the existence of demonstrable an-

Figure 5. Geometric mean of antibody level in 19 tuberculous children (groups A and B, Maybury Sanatorium) bled 5 times during interval from before vaccination to after receiving poliomyelitis booster injection.

tibodies before inoculation shows that children hospitalized for tuberculosis are equally as good subjects for immunization as are normal children. In fact, the importance of immunizing institutionalized persons is emphasized by the frequency with which epidemics have occurred under such conditions. In this very hospital, 12 cases of poliomyelitis occurred among 80 children in 1952, 2 years prior to this study.

As expected, there appeared to be no correlation whatsoever between the individual antibody responses and the character or extent of the tuberculosis. Furthermore, the response of the young children between 1 and 5 years of age was judged as good as that of the older children regardless of whether they received 2 or 3 inoculations of vaccine. This important observation of the efficacy of vaccine in the younger age group is a forerunner of more extensive data representing studies in infants and preschool children (13) to be published soon from this laboratory.

The gradual decrease in antibody titer during the period following primary vaccination has been described elsewhere (14-16), but the sharp booster effect of subsequent inoculations in the individuals in this study not only demonstrates the beneficial effect of the booster but suggests strongly that, regardless of the level of demonstrable antibodies at that time, significant immunization did persist after the primary stimulation.

Summary

The serologic response of children inoculated with gamma globulin 3 days prior to active immunization with poliomyelitis vaccine was measured by the virus laboratory, University of Michigan School of Public Health. The consistent rise in antibody titer in the children in the study demonstrates that passive immunization of this extent has no suppressive effect on the individual's response to the vaccine.

The vaccination of children hospitalized for tuberculosis resulted in antibody levels consistent with the response of normal children and indicated that immunization of tuberculous individuals should be practiced. The effect of 2 inoculations was equally as good as that of 3 injections, and no significant difference was

observed in the response of 1- to 5-year old children as compared with that of older children, 6 to 12 years of age.

The booster effect of secondary vaccination almost 1 year later is demonstrated and discussed.

Increase in Nuclear Reactors

The number and heat capacity of nuclear reactors in the United States, used to generate electric power, will increase predictably, according to the Division of Sanitary Engineering Services, Public Health Service. There will be a parallel increase in the quantity of radioactive byproducts, it is said, with a corresponding need for protective practices.

The first reactor began operation in 1942. By the end of 1955, there were 22 reactors in operation, with a heat capacity of 100 megawatts. As of February 1956, approximately 40 nuclear reactors, about one-half of which are for the production of nuclear power, were in some stage of design or construction. Seven new reactors, with a heat capacity of 90 megawatts, are expected to begin operation during 1956.

Radioactive wastes from reactors must be segregated or diluted to tolerable concentrations. At present, underground storage and ocean burial are among the methods used or proposed for segregation. Both the economy and the adequacy of these methods are under continuing investigation in anticipation of the probable increase in volume of radioactive wastes.

It is estimated that nuclear power plants completed during 1964 alone will have a power level exceeding 2.25×10^6 kilowatts, producing wastes each year of 3.3×10^{10} gallons containing 10 millicuries per gallon. An indication of the magnitude of this activity is that the entire flow of the Mississippi River would not be sufficient to dilute to permissible concentrations the fission products from these plants. Such a method of dilution, of course, is obviously least likely to be used.

Hospital Problems of Mass Evacuation

By HAROLD M. ERICKSON, M.D.

HOSPITALS, particularly those in target areas to be evacuated, have one of the most important and yet most complex roles of any group in civil defense. Removal of persons who are ill or who are recovering from injury is obviously a much more difficult job than moving able-bodied persons. This, however, is not the only problem of the hospital. Arrangements must be made for continued care of hospital patients either in expanded hospitals at a relatively safe distance from the civil defense impact area or in an emergency hospital. Either or both must be established by the hospital staff with the aid of whatever mobile hospital teams might be available.

Natural disasters as well as manmade disasters may require mass evacuation. Fire, flood, earthquakes, tornadoes, and hurricanes are always with us. One can scarcely pick up a newspaper or turn on a news broadcast without hearing of a disaster some place in the world.

No hospital is free from the possibility of having to evacuate, and, certainly, every hospital may be involved with the care of patients who have been evacuated or with those who become ill or are injured during an evacuation.

During "operation greenlight," a practice evacuation in Portland, Oreg., in 1955, 100,000 persons were evacuated from the downtown area in 34 minutes. This shows what can be accomplished through careful, advance planning. But it was not a test for Portland hospitals since none of them were evacuated.

Dr. Erickson, Oregon State health officer, delivered this paper at a meeting of the Oregon Association of Hospitals in October 1955 at Gearhart, Oreg.

Imagine a real alert at 3:00 o'clock in the morning instead of 3:00 in the afternoon, with a howling wind and heavy rain falling and darkness blanketing the area. What would happen at the hospital? Most of the Portland hospital administrators would probably be at their homes fast asleep. On awakening, what would be the administrator's first thought? Could he reach the hospital? If not, who would be in charge? Is there a plan for evacuation that is well known to all of the staff, or would chaos develop and removal of patients be impossible because there had been no advance planning?

An evacuation experienced in Oregon during the Vanport flood in 1948 will illustrate what can happen in a disaster. Fortunately, the Vanport Hospital had been evacuated in advance, but some 15,000 to 20,000 people were still housed in Vanport on that Memorial Day afternoon. In Portland, adjacent to Vanport, several of the Red Cross staff members and I were in the offices of the Multnomah County Chapter of the American Red Cross planning the evacuation of Vanport. The weather was ideal. At 4:00 p. m. our planning was interrupted by word that a railroad fill, holding off the flood waters of the Columbia River, had given way, and the city of Vanport, built to house 40,000 to 50,000 people, was being engulfed by a flood of water.

Pandemonium soon broke loose in the chapter offices. Telephone lines were completely blocked by incoming calls. Volunteers jammed the offices. The first thought of the chapter's medical department was of infants and small children. Milk and baby food were ordered through the chapter, but we were helpless to do much more without communications.

The director of the medical department and

I walked to the offices of the Oregon State Board of Health a few blocks away. In a short time we had a large number of the health department staff on duty. A switchboard operator and eight trunk telephone lines were available to us, but we could not make efficient use of them because we had no communication with the Multnomah County Chapter, and we finally went back to that office. There we learned that a request had come through for 20 physicians to report in the neighborhood of Vanport. We did get calls through to a number of doctors, but to this day I do not know whether they were able to reach the area since the streets and highways in the vicinity, we learned later, were completely blocked both by cars that were fortunate enough to get out of Vanport and by sightseers and others trying to reach the scene. In the excitement, it took only one or two stalled cars to block the limited number of roads out of Vanport. Hundreds of cars were completely flooded over; two-story houses were washed hundreds of feet off their foundations—many of them collapsed. But fortunately, only 19 persons lost their lives. There were very few, if any, injured.

At 10:30 that evening the milk and baby food we had ordered were available for delivery to the shelters. Two nurses and I were designated to make the rounds of the some 20 shelters within Portland. That was an enlightening experience. As we reached the various shelters, we found in most instances that babies as well as other evacuees had been fed. People were lined up for blocks near the shelters—not to receive aid but to offer blankets, clothing, food, and their own homes for housing the evacuees. During the first 2 or 3 days, irrespective of race, the majority of the evacuees were housed in private homes. One school was designated for the care of infants and children who needed special medical and nursing supervision. A number of children had measles and there were other illnesses. One outbreak of food poisoning resulted from hasty preparation of sandwiches and lack of refrigeration facilities in one of the shelters.

In brief, during the first few hours communications and transportation broke down, and the residents of the area were entirely dependent on their own resources. From this

experience, I believe we can rely to a great extent on the ingenuity of people and on volunteers if a disaster is not too great. In this instance, a population of less than 20,000 had all the resources of Portland, a large city of more than 350,000, to give aid. After 48 hours, the American Red Cross, Portland Housing Authority, and many governmental and volunteer agencies together did an outstanding job of rehabilitation.

In New Jersey, the experience of the Perth Amboy General Hospital in two disasters is worth review (1-3). Hospital officials met the first, a munitions explosion on four lighters at the South Amboy docks in 1950, with a plan for emergency accident patients, drawn up the month before. The plan worked moderately well, and, with its flaws remedied, the hospital was really prepared for the second disaster, a railroad wreck in 1951.

Certainly we can profit from experiences in disaster, particularly from the experiences of hospital administrators (1-8). In the hospital reports, one statement appears time and again: "Advance planning for disaster is essential if unnecessary loss of life is to be prevented and the needs of patients are to be taken care of in an emergency; there is no substitute for advance planning.

In an evacuation of the Portland metropolitan area, as in any other city the same size, 500,000 persons would have to be moved out. Portland hospitals would have to transport some 3,000 patients; 1,300 of these would be surgical cases and 300 serious medical cases. There would be approximately 100 obstetrical cases, 150 newborn infants, and perhaps 10 or more premature babies that would require special care. In addition to these, a portion of the 2,500 persons who become ill each day would require hospitalization and would have to be cared for. It is estimated that at least 5,000 persons would require first aid or even hospital care as a result of injuries incurred during the evacuation. An additional 3,000 to 4,000 beds would be needed. All of the supplies and equipment would have to be provided locally, at least during the first 24 hours or so until the hospital supplies stockpiled by the Federal Civil Defense Administration could be made available.

The Questions

What then are some of the specific problems faced by the hospital administrator? Getting back to the warning at 3:00 a. m. on a stormy night, with 4 to 6 hours expected before an attack, problems would be:

1. How will staff members be notified? Which ones should be called and who should notify them?

2. Which patients are to be evacuated and which must be left because they are in too critical a condition to be moved?

3. Where will the critical patients be moved to in the hospital?

4. Who will be left in attendance?

5. Where will the patients that are being evacuated be transported to?

6. Which patients will walk out of the hospitals and by what route? Where do they report? Who directs their leaving?

7. Will helpless patients be moved by stretcher, litters, or wheelchairs, or will beds be moved?

8. Who accompanies the patient?

9. If power fails, is there provision for emergency lighting? What substitutes are there for power?

10. How do we avert panic?

11. Who sets up the temporary hospital, if that is necessary?

12. Where will supplies and equipment be obtained? Where will staff be obtained?

13. How will the staff and patients be fed?

14. What sanitation facilities will be used?

15. What records are essential?

16. How will relatives and other interested persons be notified?

17. Will mortuary services be available? How will the dead be cared for?

18. Who will assume responsibility for various activities if key persons are not available?

19. Can volunteers be used?

These are some of the questions the administrator of the hospital in the evacuation area would face. The hospital outside of the impact area would have additional problems.

Administrators of the receiving hospitals may be warned that patients are being brought to their hospitals. Without prior planning, however, their first knowledge of evacuation might

be on the arrival of patients. These hospital administrators would face additional problems:

1. How will traffic be controlled outside the hospital and inside the hospital?

2. Where are the keys to the various services?

3. What areas of the nonevacuated hospital are to be used for the screening of patients, first aid, additional surgeries, wards, and other necessary emergency services?

4. Are additional hospital supplies and equipment available? If so, where? How will they be obtained? How transported?

5. Where can additional blood and blood plasma be obtained in an emergency?

6. What will be done about supplies and equipment that are offered to the hospital?

7. How will relatives, visitors, and the press be handled?

8. How will admissions and discharges of patients be handled and recorded?

9. Will orderlies and housekeeping personnel as well as other key personnel have transportation to the hospital?

10. Will staff members and pretrained volunteers have personal identification to allow passage through road blocks and guarded centers?

I'm sure that hospital administrators will think of many more questions that need answers. We all realize that order or chaos in an emergency will depend on whether or not these questions have been considered and plans made in advance. Again, and we cannot emphasize it too often, advance planning is a must.

Planning Principles

What are some of the principles of planning? Briefly outlined, they are:

1. Anticipate the worst possible disaster that might strike the hospital without completely destroying it and plan for this. The resulting plan will enable the staff to handle lesser disasters more effectively.

2. Cooperative planning is best. Bring as many hospital staff members as possible, including the medical staff, into the planning. Forming the nucleus of the planning group may be the hospital administrator, the medical chief of staff, and the director of nurses. A trained public health worker might be invited to join

this group. Other staff members can be called upon when planning in specific services is required.

3. Develop a simple and flexible plan. You cannot plan for every disaster, but a simple, flexible plan can be easily modified as the exigency demands.

4. Correlate the hospital plan with that of the local civil defense agency, fire department, police department, health department, and other agencies that might be concerned.

5. Plan for communications. Arrange for messenger service and two-way radio as substitutes for the telephone, if it should be out, and have a battery-operated radio set available. In planning notification of staff members, remember that the switchboard operator can call only a limited number of persons. Chain-type calling has proved of value.

6. Provide for emergency lighting, water supply, and sanitation facilities.

7. Consider making available a helicopter landing strip at the hospital or nearby.

8. In stocking supplies, some hospitals that have experienced disasters planned initially on having at least 1 month of supplies on hand. Now, the same hospitals are planning on 2 to 3 months of supplies, which they believe will take care of the average disaster. The issuance of moderate amounts of supplies during the emergency and moving them in boxes has been of value in conservation. Get information on reserve medical supplies and equipment available from other hospitals or medical facilities in a nearby area.

9. Keys labeled for all essential parts of the hospital and placed together in a locked box that is to be opened only in an emergency has been a demonstrated aid.

10. Decide on essential records, their preparation, and routing. Designate a responsible staff member and alternates to list daily evacuable and nonevacuable patients.

11. Arrange for emergency mortuary services.

12. A list of volunteers should be considered. It has been pointed out, however, that unless the volunteers are recruited in advance and trained and oriented as to their function in a disaster, they may be of little use. They may, in fact, be a handicap.

13. Plan emergency housing and feeding for the staff, including volunteers. Determine source of food supplies.

14. Assign in writing responsibilities, duties, and priorities of functions to each staff member and pretrained volunteer, designating as many as five alternates for each key position.

15. Avert panic. Psychiatrists tell us that the best way to prevent panic is to give everyone concerned a job to do, familiarize him with the job, and let him do it in the disaster. Combating rumors and giving people an opportunity to discuss their fears and problems is the best approach to psychiatric first aid.

16. Have a check list. Be sure that all details have been considered.

17. Familiarize the entire hospital staff with the plan.

18. Conduct realistic exercises that are as complete as possible.

19. Review the disaster plan and amend it as needed.

These are some of the general principles—a skeleton outline to be enlarged upon and filled in with many administrative details.

To quote from a conclusion reached at a recent meeting in Chicago called to plan for disaster in schools: "Manmade disaster may come and go, but natural disaster is always with us; let's be prepared."

The Biology of Northern Mosquitoes

By W. C. FROHNE, Ph.D.

IN the last 10 years, northern Canada and Alaska, the continent's northwestern defense front, have witnessed a construction boom. In this mosquito-infested arctic wilderness, military bastions, power dams, and metallurgical plants are being erected, and oil fields and mines are being developed. A major handicap to this growth has been the seasonal swarming of mosquitoes.

Both the Canadian and United States Governments have directed scientific studies of these insects to establish their importance to public health and to improve the contributions of entomology to polar medicine.

Canadian entomologists and personnel of the Arctic Health Research Center have pushed back the frontiers of Alaskan insect lore and have provided basic biological contributions to knowledge of mosquitoes. A few years ago they discovered a hitherto unrecognized type of life cycle characteristic of many arctic mosquitoes. This discovery will serve, in conjunction with another well-known cycle, as a framework for this discussion.

The role of the northern biting Diptera, including mosquitoes, as disease vectors is largely unexplored. No one has undertaken even a pioneering general survey of pathogens associated with northern mosquitoes. Polar medical entomology today is reminiscent of the status of tropical medical entomology 60 years ago. However, studies of mosquito-borne encephalitis are progressing in Saskatchewan. In Sweden, *Aedes cinereus*, a mosquito abun-

dant in Alaska as well, was recently shown to spread tularemia. Also, in subarctic Siberia, Russians have demonstrated that mosquitoes transmit malaria and Japanese B encephalitis.

Research on disease agents associated with man and mosquitoes in the far north might reveal important pathogenic counterparts to those in temperate and tropical zones, including many only recently detected. However, at present, northern Diptera are regarded primarily as biting, bloodsucking pests.

Northern Biting Insects

In Alaska and other northern countries, the Diptera include the most offensive insect species. Of all bloodsuckers, the more than two dozen mosquito species are the worst.

We omit lesser offenders, of which the major groups are: (a) Heleidae, punkies or no-seesums, about 12 species, half of them undescribed, of the genus *Culicoides*; (b) Simuliidae, or blackflies, of 36 described species; (c) Leptidae, or snipeflies, 2 redoubtable, little-known species of *Symphoromyia* resembling horseflies; (d) Tabanidae, horseflies and deerflies, an uncertain number of forms, perhaps 20. Like the better known mosquitoes, the punkies and flies are important because the females bite man.

Need for Mosquito Control

Following the lead of military medicine, and especially the counsel of the late Dr. Joseph Mountin of the Public Health Service, health workers accept mosquito abatement as adjunct public health. Culicidology is one of the acknowledged health sciences.

During Alaska's summer, hordes of mosqui-

Dr. Frohne is chief, Entomology Activities, Arctic Health Research Center, Public Health Service, Anchorage, Alaska.

This welcome article brings together diverse information, some of it quite new, about the insect fauna of the far north, more information than has been assembled in one place before. It also highlights the paucity of our knowledge about these species, which are such powerful deterrents to the development of Alaska and which must be subdued if the natural resources of that vast land are to be exploited.

Virtually nothing is known about the disease-vectoring potentialities of arctic biting insects. Indeed, little has been learned about their feeding habits. It seems unlikely that the insects could transmit disease unless they engorged with blood at least twice, with the last feeding upon man. Single broodedness seems to be the rule among the northern mosquitoes. This suggests the probability of single feedings. Yet some of the mosquitoes live more than a year, and it would seem necessary for them to have more than one blood meal to sustain

normal metabolic activities even though much of the time is spent in hibernation. Probably many, if not all, hematophagous species do feed more than once.

But whether these creatures spread disease from lower animals to man, or from man to man, or whether they have nothing whatever to do with spreading disease, their overpowering numbers and vicious biting habits make insect control an almost necessary prelude to land development. To imply that they are unimportant from a health standpoint simply because they are not known to transmit infectious organisms is to discredit the basic tenet of the World Health Organization Charter. Thus, insect control becomes an essential function of health organizations in bringing about relief from severe insect pestiferousness.

—By JUSTIN M. ANDREWS, Sc.D., *associate chief for program, Bureau of State Services, Public Health Service.*

toes attack every exposed warm-blooded animal. Certain mammals, for example the caribou, make long annual migrations to escape them. As for man, it may well be that mosquitoes more than maladies have impeded settlement of the vast and beautiful Alaskan central valleys blessed with fish, timber, and cultivable soil.

In accordance with an ecologic principle that toward the poles species increase quantitatively but decrease qualitatively, myriads of mosquitoes of a few arctic kinds attain densities rarely approached in warmer parts of the world. Man survives the polar winter by protecting himself from frost, the summer, only by antimosquito measures. Evidently, scientific control of arctic mosquito pests is needed to facilitate orderly development of Alaskan resources.

Life Cycle Types

To compare arctic mosquitoes with those in warmer latitudes, it is unnecessary to present the customary annotated list introducing the 20-odd *Aedes*, 5 or 6 *Culiseta*, 1 *Anopheles*, and 1 *Culex* which comprise the Alaskan mosquito

fauna. Someone might be misled by apparent similarities of the Alaskan assemblage of species to stateside lists. The Alaskan list is a selected biota of peculiarly cold-tolerant forms. All belong to one or the other of two dissimilar types of northern life cycles.

Alaskan mosquitoes are invariably single brooded; there is but one generation per year. The three many-brooded life cycles characteristic of almost all mosquitoes of the United States do not occur at all, so far as is known, in the Territory.

The members of a life cycle type resemble each other in essential habits, but the species do not necessarily belong to the same genus. However, one of the northern life cycles does comprise all the species of *Aedes*. The other includes a taxonomic miscellany of the three other genera. It is sound ecology and helpful toward understanding their biologies to classify the mosquitoes by life cycle type rather than to view them as a list of scientific names.

The *Culiseta impatiens* type of life cycle was recognized as new, by the Arctic Health Research Center laboratory, from the peculiar habits of the long-lived females of a captive colony, the first such colony of northern mos-

quitoes to be established (1). It was designated the *C. impatiens* type when single broodedness and obligatory hibernation of the female, a new combination, were proved. No temperate or tropical mosquito biologies like this have been described.

Some authors have observed the nonbiting habit of first-season females, others the viciousness of second-season hibernators of this species, and as a result the literature is cluttered with contradictory appraisals of *C. impatiens* as a pest.

It was soon obvious, from otherwise puzzling field data, that *Culiseta alaskaensis*, as well as the local *Anopheles* and *Culex*, shares the new type of life cycle (2). In this cycle the habits of females are sharply divided between the two summers they live. Courtship and mating take place the first summer, engorgement and oviposition the second. An adult *C. impatiens* female survives 10 or 12 months. After mating, the females find shelter for diapause. This rest period of estivation and hibernation lasts as long as 10 months in nature; it is as brief as 3½ or 4 months in the laboratory colony where it ends abruptly with many females spontaneously rousing to seek blood.

Normally, the blood lust appears concomitantly with increasing light in early spring, and the hibernators will bite at near freezing temperatures in order to develop and lay the egg rafts about 2 weeks later. The comparable preoviposition period of *C. alaskaensis*, however, averages much longer, 32.1 days. In both instances the preoviposition periods are unprecedentedly extended as contrasted with those of temperate zone mosquitoes. *Culiseta inornata* of the northern United States requires only 5.3 days (3). Many tropical *Anopheles* actually engorge, develop, and lay eggs all within a 24-hour period.

The preoviposition periods of *C. impatiens* and *C. alaskaensis* were not curtailed under experimental conditions at temperatures above 20° C. Such abnormal warmth merely caused excessive mortality. Eggs, larvae, and pupae of forms subject to the *C. impatiens* cycle develop without diapause in relatively warm permanent or semipermanent waters.

Another cycle characteristic of all Alaskan northern *Aedes* was made known by Wesenberg-

Lund of Denmark 35 years ago (4). He designated it the *A. cinereus* cycle. Hibernation takes place in the egg, and all the forms are obligatorily single brooded. Larvae, and sometimes the pupae, tolerate cold well. *Aedes communis*, for instance, can develop normally in water as cold as 2°–3° C. Females of this type mate, engorge, and oviposit within a few weeks after emergence in May or June. Eggs are laid in drying basins of vernal pools or along the dried margins of less transient standing waters.

Cold Resistance

Pronounced cold resistance characterizes winter and spring stages of northern mosquitoes, namely, the eggs of *Aedes* and the adult females of other genera. At these stages the pests withstand months of heavy frost and the fluctuating temperatures of spring breakup. Activities of the adult hibernators are also surprisingly independent of moderate cold above freezing. *C. impatiens* females have been observed in January and February frisking on the wing and resting on the snow.

However, specific differences of degree of cold tolerance significantly distinguish the less adapted stages in both cycles. The score or so of *Aedes* can be arranged naturally in serial order based on water temperatures typical for a critical advance in stage: (a) temperatures at which the eggs hatch; (b) temperatures characteristic of mass pupation; (c) the seasonal order of appearance of the species on the wing. Whether the criteria used be (a), (b), or (c), the resulting arrangement is practically the same. Larvae of the earliest species may precede the latest in subarctic Alaska by 2 months (5). Thus the observer dips the former from bleak snow-melt pools after cracking the ice cover of the preceding night, whereas he encounters the latter during the bright, warm days of lush new foliage in early summer.

However, surveys which classify mosquito species according to breeding area, region, and elevation rather than by collection data are particularly instructive. Lumped records for a given species from different habitats may be deceptive where there is thermal individuality dependent on size, exposure, source, and depth of breeding waters as well as their altitude and

latitude. Unexpected contrasts in optimal temperature ranges sometimes isolate the most closely related species. For example, *A. communis*, one of the earliest larvae thriving in the lowest temperature range is nevertheless close taxonomically to *Aedes pionips*, a late warm-water larva. Larvae of all forms manifesting the *C. impatiens* cycle presumably never tolerate cold as well as any of the *Aedes*, and larval cold tolerance is thus closely bound up with life cycle type. Cold tolerance and cycle type are not only implicated in larval habitat preference, but also in geographic distribution (6).

Distribution

Geographers define arctic, subarctic, and temperate regions by physical criteria stressing winter cold and latitude, such as January isotherms and distribution of permafrost. To explain insect distribution in Alaska, zoogeographers must emphasize vegetation types and warmth during the all-important summer. Otherwise the terms arctic, subarctic, and temperate have practically no meaning.

The Territory is mountainous, and alpine arctic islands above the low timberline at 1,500–2,000 feet are strewn helter-skelter over temperate and subarctic regions. Moreover, without regard to elevation, there are vast remnant glaciers of the Pleistocene ice sheets which chill “temperate” southeastern Alaska. (These ice sheets never covered the arctic and melted in most of the subarctic at the time they receded from the northern United States about 5,000 years ago.)

For example, although southeastern Alaska is designated “temperate” because of the mild winter climate, its cool summers limit the fauna to hardy forms. In the warmer subarctic, where maximum summer temperatures are 90°–100° F., southerly species, such as sun-loving *Anopheles* occur. Finally, “arctic” treeless tundra extends far into the subarctic in western Alaska and merges with the Aleutian grasslands at the latitude of temperate southeastern Alaska.

In the arctic there are wooded valleys of spruce, willow, and birch representing to the biologist simply subarctic inclusions comparable to the arctic alpine inclusions. In fact,

the “hemiarctic” zone proposed by Rousseau, which means demarcation between arctic and subarctic, may constitute a broad band of transitional parkland (7).

Trees are an important part of the environment to mosquitoes. Culicidologists conveniently designate forest forms “woods” mosquitoes. Species of open country are “tundra” or “prairie” mosquitoes. There is a sound ecologic basis for the practice. As more is learned about the distribution of northern mosquitoes in forest or treeless areas, apparent contradictions are resolved. It is essential to stress local habitats and to soft-pedal climatic regions for progress in understanding distribution. Nevertheless, interesting contrasts of arctic, subarctic, and temperate lists of mosquitoes may be made with reference to their qualitative and quantitative compositions, biologies, seasonal histories, and the practical importance of some species as pests.

Arctic Fauna

Several excessively abundant so-called dark-legged species of *Aedes*, especially *communis* and tundra forms of the *punctator* complex, are the most important arctic mosquitoes (8, 9). When *Culiseta* occur at all there they are scarce and restricted to wooded valleys. *Culex* and *Anopheles* are absent, and any importance of the *C. impatiens* type of life cycle is academic in the arctic. For this reason, too, the mosquito-biting season lasts less than a month, even though at peak it is probably the most intense in the world.

Subarctic Fauna

The rich and varied subarctic mosquito fauna contains about 2 dozen species belonging to both of the northern types of single-brooded life cycles. The very large *Culiseta* pests of early spring are joined during May and June by 8 or 9 small dark-legged *Aedes* and later further reinforced and replaced by about as many, typically larger, banded-legged kinds. Two retiring and local *Anopheles* and *Culex* species at their northern limits emerge in midsummer. Over vast areas the mosquito-biting season extends from late April to early August, or nearly 4 months. Mosquito densities are high in the interior valleys and locally along the coast at

mouths of streams, causing severe pest problems in the flat areas most desirable for human habitation.

Temperate Fauna

The so-called temperate southeastern Alaskan mosquito fauna is rather similar to the subarctic list shortened to a dozen species (10). *C. impatiens* appears early (March) in hordes. *C. alaskaensis* occurs only as far south as Haines, the northern gateway to southeastern Alaska and the sole locality in the region for *Culex*. *Anopheles* is absent, too, so far as known. In compensation, two Californian species of *Culiseta*, *incidens* and *maccrackenae*, have entered from the south. Either species may pursue a temperate zone life cycle; be multibrooded or have larval hibernation. Unfortunately, both species are rare and their biologies uncertain in Alaska.

The mosquito-biting season in southeastern Alaska is approximately 5 months, but pest problems are markedly local and are almost always due to forms of the *A. punctor* complex, for example, *Aedes punctodes*, a salt marsh breeder. The dark-legged species with, of course, the *A. cinereus* cycle, thus so predominate that southeastern Alaskan mosquitoes, both taxonomically and biologically, resemble the arctic and subarctic faunas rather than typical temperate zone mosquito faunas.

Mosquitoes of all three life zones in Alaska are different from most stateside mosquitoes, but as they have a great deal in common, it seems logical that they be studied and controlled from a central headquarters in subarctic Alaska.

Larval Habitats

Definition of the typical larval habitats of insects harmful in adult stages facilitates further biological study and makes species sanitation feasible. As an extreme example, for many years Alaskan entomologists have been stymied in studies of the common snipefly pest, *Symphoromyia atripes*. They could not find its breeding places, immature stages, or the males. In 1955, however, the first newly hatched Alaskan *Symphoromyia* appeared in emergence traps put out in mountain meadows for sampling alpine insects. It is at long last reasonable

to anticipate progress in learning the biology and planning the suppression of snipeflies.

In the main, the most harmful Alaskan mosquitoes worthy of special suppression measures include *A. punctor* forms, *communis*, *impiger*, *excrucians*, *fitchii*, *intrudens*, *diantaeus*, and *C. impatiens* and *C. alaskaensis*. It is difficult to be objective quantitatively about culicine larval populations; the common forms are usually listed for the sake of completeness from a wide variety of marginal atypical habitats. However, only favorable habitats, where a species is so abundant as to cause concern, ought to be considered typical. By reasoning so, at any rate, it has been possible for entomologists to characterize the habitat of each Alaskan mosquito, for all practical purposes. Several representative examples of Alaskan mosquito habitats have been described in detail elsewhere (11-13).

Quaking Bogs

Public Health Service entomologists have shown that *Drepanocladus-Carex* quaking bogs are the preferred larval habitat of only one Alaskan *Aedes* (11). In his northern Michigan sphagnum mat-mosquito study, Irwin (12) reported a perplexing wiggler resembling *A. diantaeus*. The new species was described by Smith (13), who discovered it in a Massachusetts quaking bog, and named *Aedes pseudodiantaeus* (now called *Aedes decticus*). It is now practicable to study the biology of *A. decticus* where it abounds in Alaskan quaking bogs.

Permanent and Semipermanent Waters

The characteristic mosquitoes of weedy lake-shores and permanent ponds in Alaska are *Anopheles* and *Culex*. Their specific environmental requirements differ markedly, nevertheless. The sun-loving *Anopheles* occurs in the open, and especially in warmer water than the shade-loving *Culex* which hides in clumps of *Carex* and other sedges.

Dystrophic ponds within bogs are the preferred habitat of *C. impatiens* and *C. alaskaensis*. However, the *C. impatiens* female deposits her raft freely on the open water of weedless basins whereas *C. alaskaensis* oviposits chiefly within dense clumps of dead *Carex*. Consequently it is feasible to predict, in regions where

both species occur, which larva will predominate in a particular pond. *Culiseta morsitans* also breeds in pondlike bog inclusions but primarily in senescent bogs of the *Sphagnum-Ledum-Picea* class which are choked with *Myrica gale* or *Carex*.

Tundras

In the boggy pools of the vast arctic and subarctic tundra waterscapes, there develop distinct tundra varieties of two species of the *A. punctor* complex. Whatever the taxonomic category to which these perplexing varieties are assigned, they certainly constitute major pests. It was recently shown (14) that the *A. communis* form, breeding in the brushy inclusions of the tundra and alpine meadows, manifests habits not typical of the species. The males are able to swarm for mating in the open treeless wastes even though *A. communis* is typically a "woods" mosquito swarming only in deep shade. Possibly this open-country form should be considered a tundra variety of *A. communis*.

Salt Marshes

Alaska has an important salt marsh mosquito pest which belongs to the *A. punctor* complex like the principal tundra pests. It breeds in myriads in arctic, subarctic, and temperate brackish coastal marshes. Dyar designated this form *A. punctodes*, and it may be necessary to restore its specific standing when the puzzling *A. punctor* complex becomes better understood. At any rate, the basic knowledge of its biology for settling academic questions and undertaking practical control of salt marsh mosquitoes is now being acquired (15).

Summary

Certain general correlations of life cycle with cold-tolerant stages and geographic distribution of mosquitoes in Alaska have been noted. Similarly, there is correlation of habitats with type of cycle. The species belonging to the *Aedes cinereus* cycle breed in temporary waters or the drying margins of semipermanent waters. The earlier species develop in snow water retained by the underlying frost. The later species require water which persists longer. Species of the *Culiseta impatiens* cycle, however, occur only in permanent waters or the most persistent

residual pools of semipermanent waters. There are no Alaskan species known to breed normally either in artificial containers such as tin cans or in treeholes, the water of pitcher plants, or other small collections of water.

idea

Piggyback Blood Testing

The Sheppard vacuum-packed blood-testing tube has been used in mass blood-testing programs by many State, county, and city venereal disease programs for the past 5 to 7 years.

The Sheppard tube proved to be a valuable aid to the speed and efficacy of mass blood testing. Occasionally, however, a tube with a faulty vacuum would fail to draw blood, necessitating a second attempt.

Survey workers using the tubes readily developed the technique of

leaving the first needle in the vein and inserting the needle of a second tube into the rubber sleeve of the first, releasing the vacuum and drawing blood into the second tube via the first tube, thereby avoiding a second venipuncture.

The picture above, taken by Dr. Charles M. Cameron, Jr., of the University of North Carolina School of Public Health, shows blood specimens being taken in this manner during the Cherokee Indian Reservation multiphasic survey conducted by the North Carolina State Board of Health in April 1955.

As a result of this experience in the piggyback method of blood drawing, the District of Columbia De-

partment of Public Health has combined both syphilis and diabetes detection in a mass blood-testing program.

Prepacking the second tube with 30 milligrams of sodium fluoride is the only special preparation required for the dual testing. The sodium fluoride acts as a sufficient anticoagulant for 3 cubic centimeters of blood and allows refrigeration storage of the specimen until it reaches the laboratory.

The piggyback blood-testing method was introduced in Washington, D. C., in June 1955 in a house-to-house blood-testing survey. The reaction of the public was, "Two tests for the pain of one is only half bad."

—JOHN L. PENDLETON, U. S. public health representative
District of Columbia, Department of Public Health.

no single blueprint but a common pattern . . .

FOR COMMUNITY ORGANIZATION OF HEALTH SERVICES

AT the annual meeting of the National Advisory Committee on Local Health Departments, sponsored by the National Health Council, the experience of five counties in improving their health facilities illustrated the value of broad citizenship participation in advance planning—for necessary legislative action, for intensive education of the voter, and for continued maintenance of public interest in the operation of established programs.

The meeting in New York City, February 1, 1956, discussed ways of achieving community organization for improving existing health services. Speakers outlined the history of community efforts in Erie County, Pa., Burlington County, N. J., Jackson County, Ohio, Woodford County, Ky., and Saline County, Kans. The 1956 meeting was the third in a series of annual discussions on the problems of development and maintenance of local health services. The two earlier sessions were devoted to the problems of local financing and to community attitudes toward local health services.

In reviewing the committee's 8-year history, Sherwood A. Messner, chairman, traced a trend toward experimentation in health department organization. He pointed to the growing recognition that a single blueprint is not suitable for organizing health department services. Since 1945, 40 city-county health departments have been organized in 16 States. Other States have developed multicounty districts. Some States are following the traditional pattern of a health department for each county. Today there are 1,442 local health units in the Nation.

Close to 100 representatives of national health, welfare, and civic organizations and

official agencies took part in the one-day program.

Discussion brought out that the successful attempt for improving local health services has involved as many citizens as possible in preliminary fact-finding surveys of community needs as well as in the planning of subsequent publicity campaigns; that the support of every community group which might be even remotely concerned should be solicited; that timing of publicity is critical; and that, in general, campaigns should be short and intensive, leading immediately to the ballot box, if voter approval is necessary. Financing of health services appeared to be a minor problem once strong community organizations were actively involved.

Build With Voluntary Groups

"We can afford good local health services if only we want them," A. L. Chapman, M.D., medical director, Region II (New York City), Public Health Service, told the meeting.

Dr. Chapman said that people are more interested in supporting "health services" for which they feel a need than in supporting "health departments," about which they know too little. Because modern health services are difficult for the general public to understand, special efforts by community organizations are needed for interpretation of the department's complex activities.

Voluntary groups can be won to support of the health department by helping to develop services in which they have special interest, Dr. Chapman continued. The local health officer must have a talent for organization plus the

ability to educate in the broadest sense and a working knowledge of motivation techniques in order both to gain and then to keep community support, he added.

The importance of building on existing interests which the public already has in health was stressed by other speakers. Discussants agreed that it was vital to maintain public support of the health department after its establishment. Use of a citizens committee to which the department would report annually and publicity about the department's activities in the local press were two of the methods suggested for holding public interest.

Community Organization Vignettes

Case histories of the five counties revealed a common pattern of community organization even if no single blueprint was followed.

Erie County

Erie County, Pa., where voters in November 1955 approved provisions for a county health department, was represented by Russell B. Roth, M.D., chairman of the new county board of health and former president of the Erie County Medical Society. He told how an intensive publicity campaign put strong emphasis on informing the voters.

A speakers bureau in the Erie County Health Council, which organized and conducted the campaign, used dramatic examples with emotional appeal in talks before all possible local groups.

Dr. Roth emphasized the importance of enlisting the cooperation of trusted community leaders. He stressed the need for factual material pointing up deficiencies in public health.

Burlington County

Jesses B. Aronson, M.D., district health officer, Central State Health District, New Jersey Department of Health, told how Burlington County, N. J., obtained county nursing services despite community apathy toward improving health services.

With the formation of a citizens group, representing voluntary health and welfare agencies, the medical society, local boards of health, labor organizations, and civic and professional

groups, and with the advice and assistance of the State health department, the Burlington County Public Health Nursing Association was brought into being. The association is a voluntary one, partly subsidized by official agencies. The eventual goal, Dr. Aronson said, is a health department to serve the entire county.

Jackson County

A volunteer group spearheaded the successful effort to win voter approval of a tax levy to pay for a countywide health department in Jackson County, Ohio. The group conducted a 5-week information campaign, relying heavily on an active speakers bureau, newspapers, and radio.

Stating that too few local medical practitioners participated in the campaign, Mrs. John T. Sellers, vice president of the new Jackson County Board of Health and a director of the Jackson County Tuberculosis Association, questioned whether medical students are receiving an adequate understanding of public health.

Mrs. Sellers pointed to the important work done by local units of national voluntary organizations in surveying the community. Valuable assistance also came from the Ohio State Board of Health. Discussants of her talk suggested that field personnel of national agencies can emphasize to their affiliates the importance of working for local health services. Subsequent suggestions mentioned the possibility of asking affiliated agencies to report such activities in their annual reports to national headquarters.

Woodford County

Woodford was the last of Kentucky's 120 counties to install a full-time health department. A 65-year struggle by women's clubs to obtain adequate health services in Kentucky was described by Mrs. Sam Flowers, president of the Kentucky Federation of Women's Clubs.

Mrs. Flowers told how speakers appealed for support of the proposed facility at meetings of all possible groups in Woodford County. A citizens health committee was organized and included a planning board which represented all civic organizations. A photographic survey of insanitary health conditions, views of

outdoor privies, and pictures of dirty restaurants were published in the newspapers. Help was given by the Kentucky State Department of Health and by the medical profession. The measure for the new health department failed to pass the fiscal court when first presented but was successful in 1955.

Saline County

After 33 years of frustration, Saline County, Kans., also achieved success in 1955, when community interest in a mental health guidance center sparked the establishment of a countywide health department. Henry C. Huntley, M.D., assistant medical director, Region II (New York City), Public Health Service, reported Saline County's earlier attempts to achieve a county health setup.

Three Basic Steps

In summing up the group reports, buzz sessions, and discussion periods, Erval R. Coffey, M.D., health officer of Greenwich, Conn., listed three basic steps in sustaining health services:

- Learn the facts about the community and deliver the facts to the public.
- Enlist all groups in the community in the improvement drive.
- Maintain public interest after the initial victory.

The Bulletin on Local Health Units carried a story of the annual meeting in the January-February 1956 issue. The bulletin is published by the National Advisory Committee on Local Health Departments, National Health Council, 1790 Broadway, New York 19, N. Y.

technical publications

The National Cancer Institute

Public Health Service Publication No. 538. 1955. 22 pages; illustrated. 20 cents.

This brochure gives a concise history of the National Cancer Institute of the Public Health Service.

A short review of the present status of the cancer problem is followed by an illustrated account of what the institute is doing—in research, in training, and in control—to help solve the problem of cancer.

About 70 percent of the annual appropriation for the various activities of the institute is devoted to cancer research, and more than two-thirds of the funds are granted to scientists in non-Federal institutions such as universities and hospitals. Other grant categories discussed include financial support for cancer teaching in medical and dental schools, programs designed to aid young physicians and scientists spe-

cializing in cancer work, grants to State health agencies, and field investigation grants directed toward the support of such projects as studies of the incidence of cancer in relation to certain environmental factors.

Discussed are methods used to acquaint practicing physicians and dentists with new developments in the cancer field, consultation services to State health agencies, public health educational programs, the radium loan program, and cooperation with voluntary health agencies interested in the cancer problem.

Reported Tuberculosis Data Calendar Year 1954

Public Health Service Publication No. 471. 1955. 29 pages. 25 cents.

Data are presented for newly reported tuberculosis cases for the United States and each State by

source of morbidity report, activity status, form and extent of the disease, race, sex, and age. Data on X-ray case-finding activities, mortality, and public health nursing visits are also included.

Reports were received from all the States, the District of Columbia, Alaska, Hawaii, and Puerto Rico. An analysis of each table summarizes data for the years 1952, 1953, and 1954 and points out pertinent characteristics inherent in the data.

This section carries announcements of all new Public Health Service publications and of selected new publications on health topics prepared by other Federal Government agencies.

Publications for which prices are quoted are for sale by the Superintendent of Documents, U. S. Government Printing Office, Washington 25, D. C. Orders should be accompanied by cash, check, or money order and should fully identify the publication. Public Health Service publications which do not carry price quotations, as well as single sample copies of those for which prices are shown, can be obtained without charge from the Public Inquiries Branch, Public Health Service, Washington 25, D. C.

The Public Health Service does not supply publications issued by other agencies.

A preliminary report of a longitudinal study begun in 1952 on epidemiology of oral health in children, covering periodontal systemic conditions, as well as caries.

Oral Health Study in Children of Suburban Washington, D. C.

By A. L. RUSSELL, D.D.S., M.P.H.

THIS is a preliminary report on a study of oral health in a population of children as the population becomes progressively less susceptible to dental caries following fluoridation of its community water. The study is not designed as a test of the fluoride-dental caries relationship; the study plan assumes that this relationship is fully established and that a progressive inhibition of dental caries will, in fact, occur. The study's broad and long-term objectives are to augment the descriptive epidemiology of dental caries and to lay a foundation for a descriptive epidemiology of periodontal disease as it first appears in relatively young persons. In addition the study group has been and will be utilized, as a population of known status and background, for short-term observation of pertinent phenomena. Two such reports, based in part upon this population, have already been published (1, 2).

The present report is limited to observations on dental caries. It describes the study population, criteria and methods of examination, and the status of the group at the time of first examination in 1952 and includes summary data

from examinations in 1953 and 1954. Evidence is presented to support other findings that inhibition of dental caries in children will follow low use of a fluoridated domestic water. The continuing study is being conducted by the National Institute of Dental Research, Public Health Service, in Prince Georges and Montgomery Counties, Md., two counties adjacent to the District of Columbia.

The Study Situation

The population of Montgomery County in 1950 numbered 164,401 persons of whom 93.6 percent were white. The population of Prince Georges County was 194,182 persons, 88.2 percent of whom were white.

Both counties are predominantly urban. Only 6.4 percent and 5.9 percent of the residents of the respective counties lived on farms in 1950. The median number of school years completed by persons 25 years of age or older was 12.6 in Montgomery County and 12.0 in Prince Georges County. Median family income was \$4,532 in the one county and \$3,634 in the other (3a). The median value of one-family homes was \$16,136 in Montgomery County and \$11,696 in Prince Georges County (3b). Principal sources of income were Federal employment, wholesale and retail trade, construction, and service occupations. Only about 10 percent of

Dr. Russell is chief, Epidemiology and Biometry Branch, National Institute of Dental Research, National Institutes of Health, Public Health Service, Bethesda, Md.

the population were employed in manufacturing (4).

Compared with the United States as a whole, residents of the two counties had completed more schooling, had earned higher incomes, and had lived in more expensive homes. For the entire Nation, the median number of school years completed in 1950, by persons 25 years of age or older, was 9.3 years (5a). Median incomes were \$2,970 for urban families, and \$2,186 for rural nonfarm families, respectively (5b). And the median value of a one-family home, in urban and rural nonfarm areas, was \$7,354 (5c).

About 5,000 elementary and junior high school pupils have been examined annually since the oral health study began. The Montgomery County group is taken from an area centering around the Takoma Park Junior High School, adjacent to the District of Columbia across its northeast border. The Prince Georges County group lives in the general vicinity of the Maryland Park and Suitland Junior High Schools, near the southeast border of the District. These areas were chosen as representative of suburban Washington from the socioeconomic standpoint and because their residents have been relatively nonmigratory.

Detailed data concerning the number of topical sodium fluoride treatments were obtained for each child through a schedule completed and returned by his parents. The proportion of treated children was so high in one Montgomery County neighborhood that it seemed prudent to exclude this entire group in computing caries and eruption expectancy tables.

Data for eight schools were analyzed separately by age, sex, and school. Though the proportion of filled teeth to total caries experience was uniformly higher in Montgomery than in Prince Georges County children, all children in the study seemed to have been drawn from the same universe as regards total caries experience in deciduous and permanent teeth and in eruption of permanent teeth and, hence, were combined into one single group for study.

Children in the study group are furnished a fluoridated water by the Washington Suburban Sanitary Commission although at the outset of the study one small group in Prince Georges County used water from wells. Raw water is taken from the Patuxent River and from the

northwest branch of the Anacostia River. The two watersheds drain about 105 square miles to the north and east of the District of Columbia. The raw water receives similar treatment in two processing plants. Treatment includes aeration, prechlorination, flocculation, rapid sand filtration, adjustment of alkalinity with hydrated lime, postchlorination, and the addition of fluoride as sodium fluosilicate by means of dry feeders. With the exception of fluoridation these procedures have been uniform throughout the lives of the children under study. Tap water prior to 1952 was essentially fluoride free.

The fluoride feeders were started on December 28, 1951. During a period of preliminary adjustment, operation was not continuous. For this reason and because of the reservoir of fluoride-free water stored in the system of mains, a fully fluoridated water was not available at all taps throughout the distribution system until the last week of February in 1952. From that time onward, spot tap fluoride determinations carried out by the Washington Suburban Sanitary Commission have been faithful reflections of the daily fluoride levels in finished water at the filtration plants with the exception of a short period in mid-June 1952, when water in the Prince Georges County area was diluted with fluoride-free water obtained through a cross connection with the District of Columbia supply. During that period the fluoride level in the Suitland area dropped to 0.50 p.p.m. F. The District of Columbia supply has since been fluoridated. The average daily fluoride content of finished water at the Robert B. Morse filtration plant, serving generally the Montgomery County study children, was 0.98 p.p.m. F in 1952 and 0.94 p.p.m. F in 1953. The average daily fluoride content of finished water at the Patuxent filtration plant, serving generally the Prince Georges County study children, was 0.90 p.p.m. F over both years.

Methods and Criteria

All examinations have been carried out by dental officers of the National Institute of Dental Research. Mouth mirror and explorer are employed, with the child seated in a portable dental chair, under a portable examination

light. Examination results are dictated to a recorder in a code similar to that suggested by Klein and Palmer (6). Some changes have been made in the code to avoid phonetic confusion and to permit the separate notation of pit-and-fissure or smooth-surface carious lesions found on a single tooth surface. Examinations are scheduled so that each child is observed during the same calendar week on successive years.

All criteria are designed to assure the highest practicable degree of comparability among examiners:

None but positive lesions which admit the explorer point are recorded as carious.

Decalcified areas in the gingival third of the labial or buccal surfaces and opacities of marginal ridges which suggest a possible proximal lesion are recorded as questionable and tabulated as normal unless a definite enamel discontinuity is demonstrated with the explorer.

Deep pits and fissures are similarly recorded as questionable unless softened dentin is encountered by the explorer point or there is visible evidence of backward decay at the dentino-enamel junction.

A tooth is considered to be in eruption if any portion protrudes through the gum.

Criteria for the scoring of periodontal disease have been discussed in detail in an earlier report (7).

Initial Status

A total of 4,737 white children aged 5 through 15 years were examined between December 1951 and February 1952, coincident with the fluoridation of the water supply. The dental caries experience of this group of children is summarized in table 1.

Subsequent study of history records supplied by parents disclosed that 1,950 of these children had been born in and had been continuous residents of the area, except for short vacation trips in some instances, and had not received any treatment designed to prevent dental caries. Findings for this group, designated hereafter as the baseline population, were accepted as representative for children in the general area in the absence of a known caries-

1952 and 1954 caries experience of continuous-residence children of Montgomery and Prince Georges Counties, Md., who had not received caries prevention treatments.

inhibitory factor and were utilized in the construction of a family of expectancy curves for caries increments in teeth and tooth surfaces, the eruption of permanent teeth, and the exuviation of deciduous teeth. Oral findings for these children are presented in broad outline in table 2.

The general caries experience in the baseline group is considerably lower than it was in children examined initially at Grand Rapids (8), and it was somewhat below the caries levels reported at the beginning of the Newburgh and Brantford studies (9, 10). Very similar findings were returned by Arnold and McClure (11) in a study of children aged 12 and 13 years in 1939 and 1940 in Arlington, Va., another suburb of Washington, D. C., and by the Southern Maryland District Dental Society, which examined about 15,000 other children in Montgomery and Prince Georges Counties early in 1952. The findings for this separate group of children are summarized in table 3.

On the basis of these comparisons, the mean number of decayed, missing, or filled (DMF) permanent teeth in baseline children aged 11 years appears to be somewhat high. If this is true, computations of yearly caries increment based on these data will overestimate the true increment between the ages of 10 and 11 years and will underestimate the true increment between the ages of 11 and 12 years.

Table 4 shows crude caries rates for children,

comparable with the baseline group, who were observed in 1952, 1953, and 1954. Findings for caries in permanent teeth in 1953, after 1 year of fluoridation, are in general slightly higher than the findings for the baseline year though the differences are well within the range of chance variation. This has been a common phenomenon in fluoridation studies where examinations are carried out with mirror and explorer. Reported DMF means were somewhat

² Decayed, missing, or filled.

Lesions detected for the first time by mirror and explorer, after 1 year of fluoridation, are mostly lesions which began before fluoridation was instituted. By the end of the second year, however, it may be assumed that the majority of lesions detected for the first time by the explorer had their inception after fluoridation began. In the present study population, the second postfluoridation examination shows a drop in total numbers of decayed, filled, or missing permanent teeth, a drop averaging 0.27 teeth per child. Mean numbers of deciduous teeth which are decayed, filled, or indicated for extraction (def) are unchanged or slightly higher.

Mean caries data for the baseline children examined in 1952 and for comparable children examined in 1954 after 2 years of fluoridation are illustrated in the accompanying chart.

Increments of New DMF Teeth

Expectancy increments of newly decayed, missing, or filled permanent teeth over a period of 1 year were computed for each age group, by the method used in the Hagerstown studies (13), from findings for the 1952 baseline group. Baseline children aged 7 years, for example, had an average of 1.090 decayed, missing, or filled permanent teeth. Six-year-old children

¹ Decayed, missing, or filled.

² Decayed, extraction indicated, or filled.

had an average of 0.409 decayed, missing, or filled permanent teeth. The difference between these two findings, 0.681 teeth, was accepted as the expected average increase in carious permanent teeth as a group of children goes from the age of about 6½ to about 7½ years. Similar computations yielded the array of expected yearly caries increments shown in table 5.

Among comparable children examined in 1954, there were 1,218 aged 6 through 15 years who had also been examined in 1953. By matching 1953 and 1954 examination records for each of these children, actual numbers of newly carious permanent teeth were determined and analyzed as mean changes over the 12-month period. This method permitted the computation of standard error for each mean change and estimation of the probability that any observed increment varied only by chance from the absolute expectancies computed from the 1952 data. These analyses are also summarized in table 5.

If the presumptive 1952 increment rates had obtained throughout the year 1953-54, 1,130 newly carious permanent teeth would have developed in the group, or an average of 0.928 tooth per child. The actual increment was 910 newly carious permanent teeth, or an average

of 0.747 per child—a difference of 19.5 percent. It is highly improbable that this difference of almost 20 percent is due to chance variation.

About the same result is obtained if expectancy increments are based upon the independent examination conducted by the Southern Maryland District Dental Society. From their data, 1,146 newly carious permanent teeth would have been predicted for the study children during the 1953-54 school year, a difference of 20.6 percent.

Discussion

Comparisons of observed increments with expected increments, as computed from the 1952 baseline data, should be interpreted with caution. Each of the age groups in the 1952 data is an independent group, subject to biological variation. In the baseline array, DMF totals for children aged 11 years seem rather high. If this be true, the expected increment is an overestimate of DMF incidence between ages 10 and 11 and an underestimate of DMF incidence between ages 11 and 12. This factor of variation is present to a greater or lesser degree throughout the array. Little reliance, then, should be placed on the comparison of expected

Table 5. Increments of new decayed, missing, or filled permanent teeth over 12 months, from 1953 to 1954, in continuous residents of Montgomery and Prince Georges Counties, Md., who were examined in both years, used city water, and had not received topical fluoride or other caries-preventive treatments, as compared with increments computed from data for comparable children of the same counties in 1952

² Based on areas under the normal curve.

with observed increment in any specific age group. The study plan intends that age-specific incidence data shall ultimately be shown as trends, valid in themselves, with expectancy values serving only as points of departure.

On the other hand, age-specific error tends to be random, and overestimation at one age tends to cancel out underestimation at another if the entire group is considered as a unit. This is well illustrated by the close agreement between expectancy data calculated from the two independent examinations cited. No matter which one of these expectancy curves is used, the same conclusions are reached: that about 20 percent fewer permanent teeth became carious in the whole group than would have been expected on the basis of the 1952 examination and that it is highly improbable the difference is due to chance.

This particular method is not appropriate at all when applied to deciduous teeth without any means of determining whether a missing deciduous tooth has been lost prematurely or normally. On the basis of the cumulative totals shown in table 4, no change in the prevalence of caries in deciduous teeth is apparent in these study groups. Deciduous teeth in these children had been in eruption and at risk of caries for 3 years or more at the time the water supply was fluoridated.

Summary

This preliminary report has described the examination criteria for dental caries and methods in use and has defined the population under observation in a continuing study of oral health in elementary and junior high school children of Montgomery and Prince Georges Counties, Md. The two counties are adjacent to the District of Columbia. The domestic water used by these children was fluoridated with sodium fluosilicate late in December of 1951. Evidence is presented that there was a statistically valid decrease of roughly 20 percent in the number of permanent teeth becoming carious during the second year of fluoridation, judged by findings from the baseline examination early in 1952.

Tuberculin Sensitivity of Young Adults in the United States

By CARROLL E. PALMER, M.D., Ph.D., EDWARD F. KROHN, M.D.,
NICHOLAS E. MANOS, M.A., and LYDIA B. EDWARDS, M.D.

THE rapid and continued decline in tuberculosis mortality during the last decades is changing the approach to tuberculosis control. Interest in the mass X-ray survey for detecting persons with active tuberculosis is being supplemented by interest in the tuberculin test for identifying persons who have been infected by the tubercle bacillus. Large-scale use of the tuberculin test may well receive increasing emphasis for tuberculosis control programs during the coming years.

Interest in tuberculin testing programs is not new. One of the purposes of the Tuberculosis Committee of the American Student Health Association, founded in 1931, was to collect in-

formation on the prevalence of tuberculin sensitivity among college students throughout the Nation (1). And during the 1930's a number of reports were published by Long and associates (2-4), as well as by others (5, 6), on the results of tuberculin testing of college students. A standardized tuberculin product (PPD) became available during the later part of the period, and attention was also directed toward the adoption of a uniform testing technique. The reports, in general, indicated a relatively high frequency of tuberculin reactors in the west, lower frequencies in the central part of the country, and high frequencies in the east. Usually, two doses of PPD were used: a first test with 0.00002 mg. and, for nonreactors to that dose, a second test with 0.005 mg. But results were not reported separately for each dose.

By the early 1940's evidence had accumulated from various studies, particularly from the work of Furcolow and associates (7), that the so-called intermediate dose test with 0.0001 mg. of standardized PPD was sufficient to detect almost all persons with active tuberculous disease or other signs of tuberculous infection. Results of subsequent studies in this country and abroad (8-12) confirmed the earlier findings with the intermediate dose test and, in addition, indicated that most of the sensitivity brought out only by larger doses of tuberculin is not related to tuberculous infection or disease. Such low-grade sensitivity shows pronounced variation with geographic area, being almost

Dr. Palmer is chief of Operational Research, Tuberculosis Program, Division of Special Health Services, Public Health Service. From 1949 to July 1955, he was also director of the World Health Organization Tuberculosis Research Office in Copenhagen. Dr. Krohn is an assistant professor of epidemiology in the School of Hygiene and Public Health, Johns Hopkins University, and a consultant to the Tuberculosis Program. Mr. Manos, formerly in Operational Research, Tuberculosis Program, is now chief statistician in the Air Pollution Medical Program, Public Health Service. Dr. Edwards has recently returned to Operational Research, Tuberculosis Program, from 6 years with the WHO Tuberculosis Research Office in Copenhagen.

absent in some localities and highly prevalent in others. It may therefore be assumed that low-grade (nonspecific) sensitivity has inflated the frequency of positive reactors reported from studies in which either 1 mg. of O.T. or 0.005 mg. of PPD has been used as the final dose. The intermediate (0.0001 mg.) dose gradually became more widely accepted, and in 1950 it was recommended by the National Tuberculosis Association for a single-dose testing procedure (13). The intermediate dose was adopted also by the World Health Organization for tuberculin testing in its international tuberculosis and BCG programs (14).

Testing with the intermediate dose of standardized PPD-S, Palmer and associates (8, 9) found an average frequency of about 12 percent reactors among more than 20,000 young white women entering schools of nursing in various parts of the country between the years 1943 and 1949. The frequencies ranged from less than 10 percent in residents of some of the midwestern States to around 17 percent in girls from the east coast and more than 20 percent in Oklahoma, Texas, and Indiana. Canada and Babione (15), using the same dose of tuberculin for testing nearly 80,000 Navy recruits and midshipmen in 1948, reported an average frequency of 9.7 percent positive reactors. Although their results were not given by geographic area of residence, the frequency of reactors was significantly higher in the men at the Naval Training Center at San Diego, Calif., than in those at the Naval Training Center at Great Lakes, Ill.

This paper presents the results and discusses the implications of a tuberculin testing program conducted in 1949-51 among more than 120,000 young white adults—Navy recruits and college students—from almost all parts of the United States.

The study, like most public health research projects, represents the cooperative efforts of many persons and groups. In addition to thousands of young men and women who participated as subjects of study, we had the assistance of the medical corpsmen and officers of the U. S. Naval Training Center, San Diego, and Captains Sidney A. Britten and Charles A. Castle of the Tuberculosis Control Section, Preventive Medicine Division, Bureau

of Medicine and Surgery, Department of the Navy. Also cooperating were the directors of student health and their staffs at Berea College, Fort Hays Kansas State College, Iowa State College, Kansas State College, Miami (Ohio) University, Ohio State University, Oklahoma A. and M. College, Purdue University, South Dakota State College, St. Joseph's College and Military Academy, Syracuse University, the universities of Chicago, Colorado, Indiana, Kansas, Kentucky, Minnesota, Missouri, Pennsylvania, and Wisconsin, and various professional schools in New England.

Material and Methods

The major part of the study is based on the results of tuberculin testing of 83,599 white men, 17-21 years of age, as they entered the Naval Training Center at San Diego, Calif., during the years 1949-51. In cooperation with the U. S. Navy, arrangements were made systematically to test each new recruit with tuberculin, histoplasmin (16), and coccidioidin and also to obtain a complete residence history. Serious efforts were made to see that no new recruit was missed. The testing was done by a small group of medical corpsmen who were carefully instructed and periodically supervised by Public Health Service research personnel. While some turnover of corpsmen was unavoidable, one principal corpsman was in charge during most of the study period.

In addition, 38,070 white students (22,684 men and 15,386 women) 17-21 years of age were tested during the years 1949-50 in some 35 colleges and universities in 17 States, largely in the middle west. Most of the students were freshmen. The testing was done by a physician or nurse at each college although at the beginning of the program a member of the research staff of the Public Health Service was present to help standardize the testing procedures.

The entire study population, recruits as well as college students, were tested by intradermal injection of 0.1 ml. containing 0.0001 mg. of PPD-S (5 tuberculin units of the international standard PPD). Reactions were read at 48-72 hours by measuring the transverse diameter of induration in millimeters. In this report, a

reaction with an induration recorded as measuring 5 mm. or more has been designated as positive.

Residence histories were obtained by a questionnaire in which each Navy recruit and college student specified, in chronological order, each locality where he had lived since birth. Those who had spent their whole life in one State, without residing elsewhere for periods longer than 6 months, were later classified as "one-state residents." Of the Navy recruits, 56,481 could be classified as one-state residents. Of the college students, 15,148 of the men and 11,250 of the women could be so classified.

One-state residents who had never spent more than 6 months away from one section of their home State were further classified as "one-section residents."

A section consisted of a number of counties with rough adjustment in size for differences in population density. Sections were small in densely populated areas, larger in areas of low population density. A total of 49,404 recruits were one-section residents.

The questionnaire also requested information on the basis of which the type of residence was classified into four groups. Metropolitan residents were defined as those living in cities of more than 100,000 population (according to the 1940 census) or in the suburbs of these cities. Farm residents were those who lived on farms. All other types of residence were classified under the broad heading of "other." And persons with more than one type of residence were classified as "mixed."

Residents of more than one State.....	27,118	10.2	7,536	11.0	4,136	7.7
Total.....	83,599	9.1	22,684	8.6	15,386	6.8

Study of geographic differences in the prevalence of tuberculin sensitivity is based primarily on the data from the Navy recruits. The Naval Training Center at San Diego draws recruits from all over the country except the north Atlantic States and the Great Lakes region. And, as all of the men were tested in San Diego with the same tuberculin product and by the same personnel, variations (and errors) in technique would be expected to be distributed at random without regard to previous place of residence. Moreover, though the recruits cannot be re-

garded as representative of the general population of young men of the same age, one could expect those from one locality to be much the same kind of men as those from other localities.

Results

The numbers tested and the percentage with reactions of 5 mm. or more for all of the recruits and college students are given by age in table 1. The overall frequency of positive reactors is 8.8 percent, ranging from 9.1 in the recruits to

¹ Excludes States represented by less than 200 persons.

Figure 1. Distribution of States or sections of States by prevalence of positive tuberculin reactors in Navy recruits.

States represented by insufficient data are unshaded.

6.8 in the women students. The frequency increases with age, especially in the college men.

The frequency of reactors in the one-state residents was found to be lower than in those who had lived in more than one State (table 2). The latter group also includes all persons born outside of the United States. Further, in the Navy recruits, the frequency of reactors in the States from which 200 or more were tested was higher than in States represented by smaller numbers, mainly States in the north central section of the country and in New England.

The findings among the one-state residents are given in table 3 for States from which 200 or more persons were tested. Except for Kentucky, New Mexico, and Arizona, the percentage of reactors among the recruits does not exceed 12, and for 9 of the 31 States it is less than 6. The same broad pattern of geographic variation is found for the college students although the

prevalence of tuberculin sensitivity is generally lower than in the recruits.

Based only on one-section residents among the Navy recruits, the area covered by the 31 States has been divided into five different levels of prevalence of tuberculin sensitivity (fig. 1). States and sections of States have been grouped in order to show the broad geographic pattern of variation in prevalence of sensitivity. Sectional subdivisions of States have been maintained only where groups of sections appeared to have distinctly different rates from those of the neighboring sections. (For continuity, Nevada has been included although only 96 recruits were tested from that State.)

The map shows that the frequency of tuberculin reactors is less than 10 percent over most of the country, from the northwestern to the southeastern coasts. Areas of significantly higher frequencies appear in some east central States and in the southwest, but only among residents

of Kentucky, Arizona, New Mexico, and the southern part of Texas do the rates exceed 15 percent.

The frequency of tuberculin reactors varies with type of residence. Table 4 shows it is generally highest in the metropolitan and lowest in

the farm residents. It is, therefore, pertinent to consider to what extent the geographic variations shown in table 3 and figure 1 may be influenced by differences in the relative proportions of different types of residence.

from the 20 States in which metropolitan, farm, and other residents were each represented by reasonably large numbers are given in table 5. Relative frequencies of reactors for the three types of residence vary considerably from one State to another. However, as shown by the last column in the table, adjustment for the differences in distribution by type of residence has only a limited effect on the order of the 20 States as arranged by frequency of tuberculin reactors. It must be assumed, nevertheless, that type of residence is of greater importance for total frequency of reactors in other States where metropolitan areas, as defined, do not exist, or where the distribution by type of residence is for other reasons less uniform.

The frequency of tuberculin reactors in the

² Computed from mortality and population figures given in Vital Statistics of the United States, 1939-41.

Figure 2. Correlation for 31 States between percentage of positive tuberculin reactors in Navy recruits and average annual death rates from tuberculosis (all forms) for 1939-41 in the white population.

total study population, as well as in the population used for studying geographic variations, is highest in the recruits, lower in the college men, and lowest in the college women. The differences are statistically significant. They cannot be accounted for by differences in age distribution since that was essentially the same in each group. Nor can they be ascribed to the unequal geographic distribution of the groups.

As shown in table 3, for the 8 States from which more than 200 persons (all one-state residents) were tested within each of the three groups, the prevalence of reactors ranges from relatively high (Kentucky) to low (Iowa). Correction for the inequality in geographic distribution of the recruits and the college students does not reduce the differences in the total prevalence of reactors in those 8 States. The proportion of metropolitan residents is lowest in the recruits, higher in the college men, and highest in the college women (table 4). Consequently, an adjustment of the college student rates to the distribution, by type of residence, of the recruits tends to increase rather than decrease the differences between the groups.

Differences between recruits and college men with respect to tuberculin sensitivity are not found in those who had been residents of more than one State, nor in the one-state residents from States represented by small numbers

¹ Excludes States represented by less than 200 persons. ² Includes only persons classified as one-state residents.

(table 2). Nor is the relative frequency of reactors in college women consistently the lowest in all States represented in the study (table 3).

Tuberculin Sensitivity and Tuberculosis Deaths

The prevalence of positive reactors in each of the 31 States from which 200 or more recruits were tested was related to the average annual tuberculosis death rates in the white population, by State, for the 3-year period 1939-41, the midpoint in the lives of the 17- to 21-year-old recruits (table 6 and fig. 2). A high positive correlation was found, the coefficient of correlation being 0.88. That finding led to an examination of the relation between the prevalence of positive reactors and other tuberculosis death rates: sex-specific rates for the period 1939-41 and average annual rates for 1929-31 and for 1949-51, as well as the mean annual death rates for all three periods (1929-31, 1939-41, 1949-51). Coefficients of correlation range from

0.84 to 0.93. The difference is not statistically significant.

Variation in Size of Tuberculin Reactions

Results thus far have been presented in terms of the conventional definition of a positive reaction as one measuring 5 mm. or more. The use of that definition, according to recent studies in many countries (10), may mean that reactions of quite different significance are being classed as positive in different geographic areas. Distributions of the sizes of the reactions were therefore studied, and the basic data are given in table 7.

While the data are inadequate for detailed analysis by single States, pooled results from several States illustrate the difference that may be found between two geographic areas (fig. 3). The figure shows percentage distributions, by size, for reactions measuring 2 mm. or more, for recruits from four northwestern States,

Navy recruits to the intradermal 0.0001 mg. tuberculin test

Idaho, Montana, Oregon, and Washington, and from four southeastern States, Alabama, Georgia, Louisiana, and Mississippi.

The concentration of reactions on "round" numbers (5, 10, 15, and 20 mm.) is obvious and indicates inaccuracy of reading even though serious efforts had been made to obtain precise measurements. (It may be recalled in this connection that each observer tested recruits from all over the country, and thus his inaccuracy would not be expected to bias the measurement of reactions of men from different geographic areas.) A smoothed curve is superimposed on each distribution to bring out the striking contrast between their shapes. While the distribution of reactions for the northwestern States is bimodal with a minimum at about 5 mm., that representing the southeastern group of States is unimodal with a relative concentration of readings in the 2 to 10 mm. range.

Among reactions commonly classed as positive, those measuring 5 mm. or more, the results

obtained in the two geographic areas may be compared numerically by expressing the frequency of reactions measuring 5-9 mm. as a percentage of all reactions measuring 5 mm. or more. In the four northwestern States, only 10 percent of the positive reactions are less than 10 mm. in diameter; in the four southeastern States, 40 percent are less than 10 mm. Although the two groups of States represented in figure 3 were selected to show the greatest difference in the relative frequencies of small reactions, the data in table 7 indicate that the proportion of small reactions varies considerably from one geographic area to another.

Discussion

The findings of the present study confirm a number of recent reports that the frequency of tuberculin reactors among young white adults from over a large part of the United States is, today, very low—less than 10 percent at about

Figure 3. Percentage distributions of reactions measuring 2 mm. or more to the intradermal 0.0001 mg. tuberculin test in Navy recruits from four northwestern and four southeastern States.

20 years of age. In a few areas the frequency may be twice as high; but in many, and particularly in the rural parts of the country, it is below 5 percent.

In interpreting these findings it is important to appreciate that the frequency of reactors at 20 years of age represents the result of tuberculous infections that have occurred during the previous two decades. On the assumption that reversion of tuberculin sensitivity is rare, an average prevalence of less than 10 percent corresponds to an average infection rate of about 5 per 1,000 per year. A prevalence of around 5 percent found in many parts of the country implies a still lower infection rate, an average of around 2 per 1,000 per year. There is every reason to believe, however, that the risk of infection has not been constant but has declined during recent years. (Deaths from tuberculosis for the 0- to 19-year-old white population have dropped from 8.2 per 100,000 in 1939-41 to 0.7 in 1954.) At present, the annual rate of tuberculous infection in white children and adolescents over a large part of the country may well be less than 1 per 1,000 per year. Under

such circumstances, most of our children can now be expected to reach adulthood without having acquired a tuberculous infection (19).

Type of residence has been shown by many workers to have considerable influence on the prevalence of tuberculin sensitivity, and our findings are in accord. The frequency of reactors is generally higher in urban than in rural residents. Had metropolitan residents in this study been defined as persons living strictly within city limits, the difference in rates between metropolitan and other residents might have been even greater.

Significant differences are shown in the percentage of reactors among the Navy recruits and the college students, differences that cannot be accounted for by age or by type of residence. They undoubtedly reflect the various factors, including socioeconomic status, that govern whether young men join the Navy or go to college. Among the college students, a higher frequency of reactors among men than women agrees with results of earlier investigations (4, 5). It is not inconceivable that women students on the whole generally come from a higher social stratum than men. The fact that the frequency of reactors is usually about the same among boys and girls up to high school age (17, 18) points again to some form of selection as accounting for the differences between sex-specific rates in college students.

Age, sex, race, and, to some extent, type of residence and probably socioeconomic factors do not, however, account for the broad geographic variations in the frequency of tuberculin reactors among Navy recruits (fig. 1). The variations must be ascribed to other factors, some of which are known to be of influence and some whose influence is entirely unknown. To the former belong ethnic differences and the well-known tendency of tuberculosis patients to move to certain areas, particularly the southwestern part of the country. Factors like those may, to a large extent, account for the high prevalence of reactors in California, Arizona, New Mexico, and part of Texas. Of particular interest is the relatively high percentage of reactors in some of the east central States, where such factors are presumably of less importance.

The high correlation between tuberculosis

death rates and percentage of tuberculin reactors, by States, represents one of the critical results of the present study and must mean that both the frequency of low-dose reactors and the tuberculosis death rates reflect the same general features of tuberculosis in a community.

Recent years have seen a growing interest in large-scale tuberculin testing surveys. In communities where tuberculosis mortality rates are not adequate or not available, results of tuberculin testing may well be the best yardstick of the tuberculosis problem. For pinpointing localities and special situations where infection rates are still high and where energetic control measures could with profit be instituted or strengthened, the test is of unchallenged value. Where, on the other hand, the prevalence rates are low, the use of the tuberculin test as an index of time changes in the tuberculosis problem has distinct limitations. To obtain stable and representative rates would require the testing of very large groups; to estimate conversion rates or to identify an appreciable number of converters would require the retesting of literally tens of thousands of persons.

A number of studies in this country and elsewhere have shown that a high proportion of new cases of tuberculosis—in some areas most of the new cases—come from among the positive tuberculin reactors (20-25). Moreover, the risk of developing clinical disease is apparently much greater for those who have large reactions than for those who have small reactions to a low-dose tuberculin test (23, 25). Perhaps one of the most tangible benefits to be derived from tuberculin testing programs is therefore the identification of the infected persons in the community and, by careful measurement of the reactions, the selection of those most at risk of developing tuberculosis. Careful followup of that selected group can be expected to facilitate early diagnosis and treatment of active disease. And, looking to the future, research studies now in progress offer reason to hope that the antimicrobial agents already found so effective in the treatment of clinical tuberculosis may also prove effective in preventing the development of disease in persons already infected (26).

How efficient are present-day tuberculin testing procedures for excluding from among the persons being called positive those who have

not been infected with the tubercle bacillus? Material from this study, as illustrated in figure 3, shows considerable geographic difference in the sizes of tuberculin reactions generally considered positive. In the north, most of the positive reactions are large and undoubtedly represent specific infection with virulent tubercle bacilli. But in the south, and to a lesser extent in other areas, many of the reactions are small, measuring from 5 to around 10 or 12 mm. in diameter. Distributions similar to those found in the south have been reported from many countries (10) where high proportions of the population have the low-grade kind of sensitivity referred to as non-specific and where many of the small reactions obtained with a low-dose of tuberculin are believed to be cross reactions representing infection with some organism (probably nonpathogenic) which produces sensitivity to tuberculin.

Many years ago the veterinarians had to face a similar situation with the problem of the "no-lesion reactor"—cattle that reacted to tuberculin yet showed no evidence of tuberculous infection. While the problem is still far from solved, it has long been known that tuberculin sensitivity in cattle may be caused by infection with a variety of micro-organisms, including the avian tubercle bacillus, *Mycobacterium johnei*, and others. The term "nonspecific" is commonly used by veterinarians to denote the tuberculin sensitivity caused by such organisms. Although that term may not be entirely satisfactory, Paterson has recently written that: "Provided the tuberculin is defined—then the reactions it produces may be classified as 'specific' or 'nonspecific.' The reactions produced by mammalian (human or bovine) tuberculin in the subject infected by mammalian tubercle bacilli are specific, by avian tubercle bacilli, non-specific. The reaction of an avian type sensitized individual to avian tuberculin is also a specific reaction, to a mammalian sensitized, nonspecific" (27).

In the tuberculin testing of cattle, the problem of the no-lesion reactor did not become of practical concern until the prevalence of bovine tuberculosis fell to low levels, until the non-specific reactors became a significant proportion of all positive tuberculin reactors. We are now entering the same stage in the tuberculin test-

ing of humans. Our problem is no longer simply to separate persons having tuberculin sensitivity from those having no sensitivity; it includes also the discrimination between specific and nonspecific tuberculin sensitivity. While the separation of the two kinds of sensitivity has been improved by using only a small dose of tuberculin, further improvement cannot be expected by further change in dosage (28, 29). The crux of the matter is that with the tuberculin products at present available the smaller specific reactions do not differ in size from larger nonspecific reactions. We need to develop new techniques for distinguishing the two kinds of sensitivity; perhaps a more specific testing product, perhaps comparative testing techniques along the lines developed by the veterinarians to deal with the analogous problem in cattle.

Summary

Tuberculin sensitivity was studied during 1949-51 in more than 120,000 white men and women, 17-21 years of age, by testing with the intermediate (0.0001 mg.) dose of the international standard tuberculin PPD-S. The study population comprised Navy recruits from all parts of the country, tested as they entered the Naval Training Center at San Diego, Calif., and students, mostly freshmen, attending colleges and universities in 17 States. Residence histories obtained from each person at the time of the testing provided material for studying geographic differences in the prevalence of tuberculin sensitivity.

The average frequency of reactors was 8.8 percent, corresponding to an average annual infection rate of less than 5 per 1,000 during the last two decades. However, prevalence rates among Navy recruits ranged from about 20 percent in lifetime residents of Arizona and New Mexico to less than 4 percent in Idaho and Nebraska. Rates in the college students, while generally lower, reflected similar geographic differences. Residents of metropolitan areas generally had higher rates than farm residents.

A high positive correlation was found between the frequency of reactors among the

Navy recruits and tuberculosis death rates among the white populations of their home States.

The sizes of tuberculin reactions generally classified as positive showed considerable geographic differences in the relative proportions of small and large reactions. In four western States about 10 percent of the reactions measuring 5 mm. or more were from 5 to 9 mm. in diameter in contrast to 40 percent in four southeastern States. The relative preponderance of small reactions is ascribed to a low-grade kind of sensitivity not related to tuberculous infection; whereas most of the larger reactions represent specific sensitivity. Careful measurement of reactions is essential for the efficient identification of persons at risk of developing clinical tuberculous disease.

Proprietary Nursing Homes

A Backdrop of Facts **ON PATIENTS AND THEIR CARE**

By JERRY SOLON, M.A.

a
study
of the
proprietary
nursing homes
in thirteen states

INFORMATION about the patients and their care is a sensitive means of learning what type of facility nursing homes really are. Taking this approach, 13 States participated with the Commission on Chronic Illness and the Public Health Service in a study of the character-

istics and care of long-term patients in various types of institutions during 1953-54.

A full report of the study will be issued by *Public Health Reports* as a Public Health Monograph. An earlier report has been published as a reprint from *The Modern Hospital* of May 1955 by the Public Health Service under the title, "Patients in Proprietary Nursing Homes."

A description of the proprietary nursing homes of the 13 States in the study is presented here in a brief chart review.

The States in the survey are California, Colorado, Connecticut, Georgia, Indiana, Maryland, Minnesota, New Mexico, New York, Oklahoma, Rhode Island, Vermont, and Wyoming. In composite, they present a fairly representative picture of nursing home patients in the country.

The term "nursing home" was found to have

Mr. Solon, who has been serving as a research associate of the Commission on Chronic Illness for a study of long-term patients, is health program analyst with the Division of Hospital and Medical Facilities, Public Health Service. The chart review reproduced here is adapted from Mr. Solon's talks at the Commission's 1956 meeting in New York City, February 9, and at the Biennial Round Table Conference of the American Public Welfare Association, December 3, 1955, Washington, D. C.

varying connotations among the States. The range of variation was substantially narrowed by application of uniform definitions. Nevertheless, the deeply ingrained local connotations produced some varying interpretation of those definitions.

Generally, however, the types of establishments construed in the study as proprietary nursing homes include those which are defined as "skilled nursing homes" together with those defined as "personal care homes, with skilled nursing." The former provide skilled nursing care as their primary function; the latter furnish some skilled nursing care, but only as an adjunct to a primarily personal care function. These distinctions have been described in two articles in *Public Health Reports*: "Inventory of Nursing Homes and Related Facili-

ties," December 1954, and "Ownership and Size of Nursing Homes," May 1955.

Briefly, skilled nursing care includes some technical nursing procedures beyond those which the untrained person can administer. Personal care includes such services as help in walking and getting in and out of bed, assistance with general bathing, help with dressing or feeding, preparation of special diet, supervision over medications which can be self-administered, and other types of personal assistance.

There are approximately 150,000 beds in proprietary nursing homes of the two types described, as shown in the chart below. Information about the patients and their care in essentially these types of homes in the 13 States surveyed is highlighted in the other charts.

Proprietary
Nursing
Homes

..... Number of homes and beds
in the United States

*providing a minor extent of skilled nursing

AGE OF PATIENTS

Without question nursing homes today serve a very aged group. Although in other respects sharp differences are observed among the States, in point of the patients' ages the various States present a remarkably uniform picture. The median age of patients in all of these States is about 80 years.

Relatively few patients—barely 10 percent nationally—are under 65 years of age. Only about 1 percent are less than 45 years.

LENGTH OF STAY TO DATE

RANGE AMONG 13 STATES

PERCENT OF PATIENTS BY TIME SINCE ADMISSION

The long periods of residence, along with the patients' advanced ages, emphasize that nursing homes are in a real sense a form of home for the aged.

The median length of residence of the patients in the homes at the time of the survey ranged from 6 months in New Mexico to 1½ years in upstate New York. Some patients stay many years—1 out of 10 of New York's patients had been admitted 5 or more years earlier.

DISABILITY AMONG PATIENTS

RANGE AMONG 13 STATES

Nursing home patients are heavily disabled. About half of the patients are severely limited in ability to walk—they are unable to get about at all, or require some major assistance such as wheelchairs, walkers, or the help of attendants.

About one-fifth of the patients are completely confined to bed.

More than one-half are mentally confused, at least part of the time. One-third of the patients were found to be incontinent.

DIAGNOSES - RANGE AMONG 13 STATES

PERCENT OF PATIENTS WHOSE PRIMARY CONDITION IS:

A few of the more common types of diagnoses reported for nursing home patients are shown. These represent only the major condition for which the patient is in the nursing home.

Cardiovascular conditions are the most common; heart diseases and stroke cases with hemiplegia are the major components among these.

In all, it is the chronic diseases which characterize nursing home patients.

Information about the patients reveals a great deal about the character of the homes. Thus, this brief picture of the patients—aged, heavily disabled, chronically ill, destined for a prolonged stay—outlines a sharp image of the type of facility we have in the nursing home. Even the patients with fractures—normally regarded as an acute condition—usually have a fractured hip, requiring for the older person a prolonged period of care.

A particularly revealing aspect of the nursing home is highlighted by the frequency with which the nonspecific term "senility" is reported as a primary diagnosis for patients. It reflects in very large part the unavailability of more definitive diagnostic information. It points up the fact that the diagnoses reported by the nursing home administrators often lack the backing of medical records or even of medical examination. In what follows we shall see something of the character of the care rendered and of the nature of its medical orientation.

PERCENT OF HOMES BY HIGHEST SKILL-LEVEL OF STAFF

The sharp sweep of the curve marking off the proportion of homes which have a registered professional nurse tells a striking story. Connecticut, at one end of the curve, has a registered nurse in practically every nursing home—in fact, Connecticut prefers to call nursing homes "chronic and convalescent hospitals." At the other end of the curve are Wyoming and Oklahoma, where the home with a registered nurse is practically nonexistent.

AVERAGE NUMBER OF PATIENTS PER NURSE*

RANGE AMONG 13 STATES

NURSE

PATIENTS

*Includes RNs, practical nurses, and aides.

Also important is the number of staff available, in relation to number of patients. The ratio of patients to nurses of all types varies significantly among the States. In California and Rhode Island we find an average of 2.5 patients per nurse (Connecticut is close to this figure with 2.9 patients). Wyoming, at the other extreme, averages 5.2 patients per nursing staff member.

This view of certain nursing services ordinarily given in nursing homes is in key with characteristic differences among States revealed by some of the other charts. The proportion of patients who receive these particular services is shown for Connecticut and Wyoming, two States which frequently appear at opposite poles on the other measures. Much larger proportions of Connecticut's patients receive these services than Wyoming's patients.

NURSING SERVICES RECEIVED

PERCENT OF PATIENTS RECEIVING:

The extent to which patients are under close, continuing medical supervision may be a crucial indicator of the general character of nursing homes. Large numbers of the patients are in fact infrequently attended by physicians. The proportion who have not been seen by a physician in as long as 6 months or more mounts in some of the States to one-fifth, one-fourth, and even as much as one-third of the patients.

ATTENDANCE BY PHYSICIANS

PERCENT OF PATIENTS NOT SEEN IN 6 MOS. OR MORE

PUBLIC ASSISTANCE RECIPIENTS OUT OF EVERY 10 PATIENTS

Public welfare funds pay for the care of about half of all patients in proprietary nursing homes. In none of the 13 study States do public assistance recipients represent less than one-fourth of the patients. And in several of these States, as many as 7 out of 10 patients are paid for from welfare funds, usually with no other support.

There is consistently a discrepancy between the median payment for care made by public assistance agencies and the average amount paid by patients from their own funds. In some States, the welfare payment is only about half the private-pay average.

Although some of the difference may stem from the luxury accommodations private-pay patients may select, statutory and budgetary ceilings on public assistance payments are known to be a prime factor.

AVERAGE MONTHLY CHARGE FOR CARE

We have seen in this brief review that nursing homes are predominantly oriented toward long-term care, and toward an aged clientele. Their patients are characterized by a considerable degree of disability and by a multiplicity of chronic diseases.

We have observed the range in extent of staffing and intensity of nursing care. We have noted an apparent discrepancy between the character of the patient population on one hand and a relative lack of close and continuing medical attention on the other. Some fundamental implications for our concept of the nursing home role are related to the question of whether

or not nursing homes are medically oriented.

We have recognized that public welfare agencies are very heavily involved in financing nursing home care for public assistance recipients. With so large a proportion of the patients financed from this source, the welfare levels of payment must have a pervasive influence on the quality of care characteristic of nursing homes in general. How large a part public welfare agencies may have in the further development of nursing homes is suggested by their already important role in financing such care. The need for joint effort between the health and welfare agencies is all too apparent.

Effect of Fluoridated Public Water Supplies on Dental Caries Prevalence

By FRANCIS A. ARNOLD, Jr., D.D.S., H. TRENDLEY DEAN, D.D.S.,
PHILIP JAY, D.D.S., and JOHN W. KNUTSON, D.D.S., Dr.P.H.

AS EARLY as 1942, it had been adequately demonstrated that the use of fluoride-bearing drinking waters produces a marked reduction in the incidence of dental caries. It was also known by that time that this beneficial effect occurs in populations using water supplies containing fluoride from natural sources in concentrations below the level established as the threshold for mottled enamel or endemic fluorosis (1).

These epidemiological studies suggested the hypothesis that the addition of fluorides to public water supplies would result in a substantial reduction in dental caries. To test this hypothesis and to evaluate the procedure as a method

of caries control, several studies were begun in 1944-45. One of these studies is the Grand Rapids-Muskegon study, conducted by the Public Health Service with the cooperation of the Michigan Department of Health, the University of Michigan, and the city officials of Grand Rapids and Muskegon, Mich. This paper summarizes some of the findings from 10 years of observation in that study.

General Procedure

As originally planned the Grand Rapids-Muskegon study was designed to continue for a period of 10 to 15 years. This period was selected so that observations would be comparable to those obtained in the basic epidemiological studies on children 12 through 14 years of age with a continuous history of using fluoridated water. The selection of the study areas, the methods and types of examinations, the selection of the annual study groups, and preliminary findings have been reported (2, 3).

Beginning in January 1945, sodium fluoride has been added to the water supply of Grand Rapids, the principal study area. Since that time the fluoride content of the water supply has been maintained at a concentration level of 1 p.p.m. (within the range 0.9 to 1.1 p.p.m.). The water supply at Muskegon, the control area, contained less than 0.2 p.p.m. of fluoride until July 1951. At that time Muskegon began adding fluoride to its water supply to maintain a level similar to that in Grand Rapids. (In this paper, parts per million of fluoride refers to the concentration of the fluoride ion.)

Dr. Arnold is director of the National Institute of Dental Research, National Institutes of Health, Public Health Service; Dr. Dean is secretary of the Council on Dental Research, American Dental Association; Dr. Jay is professor of dentistry at the University of Michigan School of Dentistry; and Dr. Knutson is chief dental officer of the Public Health Service.

The following dental officers of the Public Health Service conduct the annual dental examinations in the Grand Rapids-Muskegon study: Dr. Robert C. Likins, Dr. A. L. Russell, Dr. David B. Scott, Dr. D. E. Singleton, and Dr. Robert M. Stephan. The following dentists, formerly with the Public Health Service, also participated as examiners in the study: Dr. F. S. Loe, Los Angeles, Calif.; Dr. H. B. McCauley, Baltimore, Md.; Dr. S. J. Ruzicka, Cleveland, Ohio; and Dr. Edwin M. Short, Hyattsville, Md.

To establish the caries status of the study population before fluoridation of the waters, complete oral examinations with a mouth mirror and explorer were made of virtually all children enrolled in elementary and secondary schools in Grand Rapids and Muskegon in 1944 and 1945. Each year thereafter, similar examinations have been made of selected samples of children in the two areas. (Bite-wing roentgenographic and bacteriological studies on selected samples of children will be reported in subsequent papers.) To provide an "expectancy curve," complete oral examinations were also made, in 1945 and 1946, of school chil-

dren in Aurora, Ill., where it is known the water supply has contained 1.2 p.p.m. fluoride from natural sources for about 50 years.

The annual samples of the school population of Grand Rapids and Muskegon are taken from schools selected as representative of each city as a whole. The samples consist of all available children in certain grades (or in sections of the grades) in these schools. The grades are selected to yield certain age groups. The number of grades has been expanded each year so that for the 10th year of the study a representative sample of children at each age from 5 through 16 years was obtained. The grades

¹ See reference 1 for information regarding the effect of selection of sample by grades on specific age groups.

² The basic examinations in Muskegon were not done until late spring of 1945; therefore, no examinations were made in the fall of 1945.

selected for the annual examinations are as follows:

Year	Grade
1945-----	Kindergarten, 1, 8
1946-----	Kindergarten, 1, 4, 8
1947-----	Kindergarten, 1, 4, 8, 11
1948-----	Kindergarten, 1, 4, 8, 11
1949-----	Kindergarten, 1, 4, 6, 8, 11
1950-----	Kindergarten, 1, 2, 3, 4, 6, 8, 11
1951-----	Kindergarten, 1, 2, 3, 4, 6, 8, 11
1952-----	Kindergarten, 1, 2, 3, 4, 5, 6, 8, 11
1953-----	Kindergarten, 1, 2, 3, 4, 5, 6, 7, 8, 11
1954-----	Kindergarten through 11

Each year of the study, all available children in the selected grades (or section thereof) in each school in the study received dental examinations. Only the records of children aged 4-16 years who had used city water supplies continuously since birth are included in this report. Not included are records of children who lived outside their respective communities

for more than 3 months in any one calendar year. The number of continuous resident children and their distribution by age for each year of the study are shown in table 1.

Results

The amount of dental caries observed at each annual examination through 1954 in Grand Rapids and in Muskegon is shown in tables 2 and 3. There has been a striking reduction in the amount of dental caries in both the deciduous and permanent teeth. For example, in 1944 the average 6-year-old child had 6.43 def (decayed, extraction indicated, or filled) deciduous teeth; in 1954 the average child had only 2.95 def teeth. This represents a reduction of about 54 percent. Similar results were observed in the permanent teeth of children born since fluoridation started; that is those 6 to

10 years old. It should be noted also that some beneficial effect was obtained by the older children. For example, the 16-year-old children had an average of 13.50 DMF (decayed, missing, or filled) permanent teeth in 1944 and 9.95 in 1954. They were between 6 and 7 years of age when fluoridation started.

A breakdown of the dental caries experience rates for 1954 in the two cities is shown in table 4. For comparison with these results, table 5 offers the findings in 1945 among Aurora, Ill., children, who had used a naturally fluoridated water since birth. The caries experience observed among them is similar to that reported for other areas with fluorides of that concentration (1).

Prior to the decision to add fluoride to the water supply at Grand Rapids, it was concluded that the procedure would not produce an un-

desirable cosmetic effect, that is, mottled enamel. However, it was recognized that an increase in the milder, nonobjectionable forms of dental fluorosis was likely. In order to evaluate this factor fully, it is necessary to wait for observations on all permanent teeth (excluding third molars) which are calcified on fluoridated water. The observations to date give evidence of only a slight increase (0.24 percent in 1944; 0.36 percent in 1954) in the number of children with the milder forms of fluorosis, which are not objectionable from an esthetic or cosmetic standpoint.

Discussion

From the results obtained in Grand Rapids after 10 years of water fluoridation, it is quite clear that this procedure is remarkably effec-

tive in reducing the incidence of dental caries. These observations are in accord with the results of similar studies conducted under separate auspices (4-6). The scientific evidence is conclusive, therefore, that water fluoridation is an effective public health procedure for producing a substantial reduction in the incidence of dental caries.

According to this study, the beneficial effects of fluoridated water are not confined to persons drinking the water since birth. The results suggest that some benefit was obtained by per-

sons whose teeth had already formed or erupted when they started drinking fluoridated water. The effects on the teeth of adults in these cities have not as yet been ascertained. However, the fact that a reduction in caries was observed for teeth which had already been calcified when fluoridation was started indicates that some beneficial effect may be gained by older age groups.

The possibility of an increase in dental fluorosis in a community after fluoridation has received considerable discussion. After 10 years

³ Decayed, missing, or filled permanent teeth; each tooth is counted only once for this total. A tooth that has both a filled and a carious surface is included under both the "Decayed" and the "Filled" columns. (Note that this table differs from table 2, reference 2.)

⁴ Permanent teeth only.

of fluoridation in Grand Rapids, the percentage of children classed as having fluorosis has increased, but, as anticipated, this increase is confined to the milder forms. As pointed out previously (7), the signs of the milder forms of fluorosis caused by ingestion of water containing 1 p.p.m. fluoride as a rule do not appear on the anterior teeth. It is the plan of this study to continue the observations to evaluate this factor fully. Thus far, however, the ingestion of the Grand Rapids water supply has not produced any undesirable cosmetic effect in the form of objectionable dental fluorosis on the anterior teeth.

Summary

The results of the Grand Rapids-Muskegon study after 10 years of observation indicate that the adjustment of the fluoride content of a communal water to an optimal level (approximately 1 p.p.m. fluoride) will produce the following effects:

1. A striking reduction in the prevalence of dental caries in the deciduous teeth. At the

peak of prevalence, namely 6 years of age, the caries rate for the deciduous teeth was reduced by about 54 percent.

2. A marked reduction in the prevalence of dental caries in the permanent teeth. In children born since fluoridation was put into effect, the caries rate for the permanent teeth was reduced on the average by about 60 percent.

3. Some benefit among persons whose teeth having already formed or erupted when fluoridation is begun.

4. No undesirable cosmetic effect from dental fluorosis.

PHS films

The Public Health Aspects of Migrant Workers

16 mm. Film, black and white, sound, 16 minutes, 1955.

Audience: Public health workers, medical societies.

Available: Loan—Public Health Service, Communicable Disease Center, 50 7th St. NE., Atlanta 23, Ga. Purchase—United World Films, Inc., 1445 Park Avenue, New York 29, N. Y.

Instruction in the detection and control of communicable diseases in migrant laborers is provided through this film. National problems in controlling diseases associated with this

shifting group are elucidated. These problems have, for many years, been growing.

Since migrant laborers are transients, they do not ordinarily enjoy the rights of citizenship. Any attempt to solve such problems must, therefore, transcend legal obligations to protect the health of citizens.

Infectious Hazards of Bacteriological Techniques Series: Part VI, The Centrifuge

35 mm. Filmstrip, color, sound, 12 minutes, 86 frames, 1955.

Audience: Laboratory or institutional personnel using or teaching the use of the centrifuge in handling infectious organisms.

Available: Loan—Public Health Service, Communicable Disease Center, 50 7th St., NE., Atlanta 23, Ga. Purchase—United World Films, Inc., 1445 Park Avenue, New York 29, N. Y.

This is one of a series of filmstrips relating to studies of infec-

Air samplers placed to determine aerosol contamination at various distances from centrifuge.

Ventilated cabinet developed at Fort Detrick to house refrigerated centrifuge.

Truck showing mode of travel of migrant laborers. Two families of 10 or 12 people traveled 1,000 miles in one of these to get to summer work.

Safety cup used to prevent dissemination of aerosols from tubes broken in centrifuge.

tious aerosols produced by common laboratory operations.

Based on data gathered by the Army's Chemical Corps Biological Laboratories, Fort Detrick, this particular part deals specifically with the centrifuge. It points out some of the hazards of using this apparatus and suggests safe operating procedures.

Microbiological Safety

By MORTON REITMAN, Ph.D., and A. G. WEDUM, M.D., Ph.D.

LABORATORY workers often have acquired infections during microbiological investigations. A 1951 survey of 1,342 laboratory-acquired infections in the United States revealed 39 deaths, a case fatality rate of about 3 percent (1). In all, recognizable accidents in the laboratory accounted for only 215, or 16 percent, of the infections. The source of most of the illnesses was unknown.

Although literature on industrial and chemical hazards is abundant, little has been published on microbiological hazards until recently (2-9). The Fort Detrick Laboratory Hazards Section, necessarily concerned with the prevention of laboratory infections, has attempted to determine their causes. From observations and from experimentation on infectious laboratory hazards, safety ideas have been developed which may be helpful in decreasing the number of laboratory-acquired illnesses.

Aerosol Determination

Studies of the potential sources of infection have centered on the hazards associated with common laboratory techniques. The experimental method used has been described previously (5, 7). Essentially, this method involves sampling air with the sieve-type air sampler during standard bacteriological operations such

as pipetting, centrifuging, inoculating and lyophilizing cultures, and autopsy of animals. The operational area is surrounded by samplers, each of which draws air at the rate of 1 cu. ft. per minute through 340 small openings, thereby impinging organisms on the surface of a petri dish agar plate 1-2 mm. below the openings. After a suitable incubation period (36-48 hours at 30° C. for bacteria and 4-16 hours at 30° C. for bacteriophage) colonies or plaques are counted in a Quebec colony counter.

Contamination of the environment is determined also by swabbing surfaces with cotton moistened with nutrient broth. The swabs are streaked on agar plates, which are then incubated as are the air-sampler plates.

Three easily identified organisms were used in these studies: (a) *Serratia indica*, a red pigmented vegetative rod; (b) *Bacillus subtilis* var. *niger*, designated *B. globigii* in Fort Detrick laboratories; and (c) coliphage T₃. *S. indica* and *B. subtilis* spores were sampled on corn-steep, molasses agar, and coliphage T₃ on tryptose phosphate glucose agar (7).

Area Contamination Found

Wide variations from average determinations of contamination hazards associated with laboratory procedures are possible (see table). These variations often seem to depend on minor changes in technique peculiar to the individual testing a particular procedure. A reported count of two, for example, means that two colonies grew on the agar sampling plates. It has been reported that most bacteria in the air occur in clumps (10). Also, the efficiency of the sieve

Aerosols produced by common bacteriological techniques

Technique	Number of colonies appearing on san plates			
	Number of operations	Average	Minimum	Maximum
Agglutination, slide drop technique (one slide)-----	60	0.3	0	
Animal injections (<i>Serratia indica</i>):				
1. 10 shaved guinea pigs injected intraperitoneally with 0.5 ml. culture, no disinfectant-----	3	15	15	
2. Same as (1) but injection site disinfected before and after injection with 1 percent tincture of iodine-----	3	0	0	
Autopsy, guinea pig:				
1. Immediately after 1 ml. <i>S. indica</i> culture injected intraperitoneally-----	2	4.5	3	
2. Immediately after 10 ml. culture injected intracardially-----	6	3	1	
3. Grinding tissue 2 minutes in mortar and pestle with 2 ml. sterile broth:				
Guinea pig liver as in (1), 10 ml. inoculum-----	10	1.8	0	
Guinea pig heart as in (2)-----	6	19.5	0	10
Centrifuging:				
1. Pipetting 10 ml. <i>S. indica</i> culture into 50 ml. tube-----	100	.6	0.1	
2. Pipetting 30 ml. culture into 50 ml. tube-----	100	1.2	0	
3. Removal of one cotton plug after centrifuging-----	100	2.3	.8	
4. Removal of one rubber cap after centrifuging-----	80	.025	0	
5. Decanting supernatant into flask-----	10	17.6	0	11
6. Siphoning supernatant from 10 tubes, each containing 30 ml. centrifuged culture-----	100	3	0	24
7. Adding 30 ml. saline to one tube of packed centrifuged cells and resuspending by mixing by alternate sucking and blowing with a pipette-----	100	4.5	.7	12
8. One 50 ml. tube breaking in centrifuge but all 30 ml. culture staying in trunnion cup-----	10	4	0	20
9. As in (8) but culture splashing on side of centrifuge-----	10	1,183	80	1,800
10. Swabbing outside of centrifuge tubes after filling, centrifuging, taking off supernatant, and resuspending-----	10	(1)		
One drop of <i>S. indica</i> culture falling 3 inches onto:				
1. Steel surface-----	200	1.3	.02	4
2. Painted wood-----	200	.3	.01	.1
3. Kem-rock-----	100	.04	.00	.0
4. Dry hand towel-----	100	.16	.00	.3
5. Dry paper towel-----	200	.11	.00	.3
6. Dry wrapping towel-----	100	.02	.00	.0
7. Towel wet with 5 percent phenol-----	100	.02	.00	.0
8. Pan of 5 percent phenol-----	100	.00	.00	.0
Inoculating loop:				
1. Streaking one agar plate with one loopful of <i>S. indica</i> broth culture-----	10	.6	0	20
2. Streaking one agar plate with one loopful of agar culture-----	15	4.6 ²	0	.7
3. Loopful of broth culture striking edge of tube-----	15	.26	0	2.3
4. Inserting one hot loop into 100 ml. culture in a 250 ml. Erlenmeyer flask-----	550	8.7	.68	25
5. Inserting one cold inoculating loop into 100 ml. culture in a 250 ml. Erlenmeyer flask-----	250	.08	0	.22

sampler in recovering aerosolized particles of heterogeneous size and composition under varying humidities is not easily nor precisely determinable. In the presence of bacterial aerosols of known concentrations, efficiencies have varied from 43 to 73 percent. Therefore, the reported number of colonies is significantly smaller than the actual number of bacteria.

It is evident that certain procedures create

larger amounts of aerosols than others. Grinding tissue with mortar and pestle, decanting the supernatant after centrifugation, resuspending packed cells, inserting a hot loop in a culture, withdrawing a culture sample from a vaccine bottle, opening a lyophile tube, streaking an inoculum on a rough agar surface, and shaking and blending cultures in high-speed mixers appear to be potentially dangerous to the tech-

Aerosols produced by common bacteriological techniques—Continued

Technique	Number of colonies appearing on sampler plates			
	Number of operations	Average	Minimum	Maximum
Hypodermic syringe and needle [withdrawing 1 ml. phage suspension from rubber-capped vaccine bottle and making ten-fold dilutions in rubber-capped vaccine bottles (10^{-1} to 10^{-9}), pledget does not always protect fingers against contamination]:				
1. Cotton pledget around needle	90	2.3	0	10
2. Ethanol soaked cotton pledget	90	0	0	0
Lyophilization:				
1. Breaking one ampule containing 2 ml. of lyophilized <i>S. indica</i> culture in milk plus broth menstruum by dropping on the floor, first 10 minutes	10	2,029	1,939	2,040
2. Same as (1), 50-60 minutes after breakage	10	741	162	1,447
3. Opening one lyophile tube by filing and breaking tip	20	86	4	256
4. Same as (3), but wrapped in 70 percent ethanol soaked cotton pledget	50	.08	0	.8
5. Transferring one dry inoculum from one lyophile tube by wire loop	50	1.0	0	5
6. Same as (5), but shaking powder into broth tubes	20	5.4	0	30
7. Same as (5), but wet inoculum transferred by syringe and needle after reconstituting with one ml. broth	10	4.4	0	17
Petri dish plates:				
1. Preparation of pour plate, pipetting one ml. inoculum of <i>S. indica</i> into plate without blowing, and adding melted agar and mixing	15	2.6	.2	5
2. Streaking one smooth agar plate with 0.1 ml.; spread with glass rod	50	.06	0	.4
3. Streaking one rough agar plate with one loopful of broth culture	10	25.1	7	73
4. Same as (3), but using 0.1 ml. and glass rod	50	8.7	2	25
Pipettes (also see centrifuging.):				
1. Inoculating 50 ml. broth in 125 ml. Erlenmeyer flask with 1 ml. culture (<i>S. indica</i>)	5	1.2	0	2
2. Mixing 7 ml. broth culture by alternate suction and blowing, without forming bubbles	5	.2	0	1
Plug, stopper, or cap removed from culture container of 1-10 dilution of 24-hour broth culture of <i>S. indica</i> :				
1. Escher rubber stopper removed from 5-oz. square dilution bottle immediately after shaking up and down	15	5.0	0	20
2. Same as (1), stopper removed after 30 seconds wait	15	2.5	0	12
3. Plastic screw cap removed from 8-oz. prescription bottle immediately after shaking	15	4.0	0	13
4. Cotton plug removed from 250 ml. Erlenmeyer flask immediately after rotary shaking (dry plug)	15	5.0	0	16
5. Same as (4), but wet plug	5	10.2	0	35
High speed blender, <i>S. indica</i> culture mixed 2 minutes:				
1. Screw-capped, no rubber gasket (1 minute)	10	8.7	0	31
2. Screw-capped, rubber gasket, worn bearing	10	61.0	12	126
3. Loose fitting plastic cover	15	518	77	>1,246
4. Removing tight cover immediately after mixing	15	(¹)	(¹)	(¹)
5. Removing tight cover 1 hour after mixing	15	8.2	5	33

nician if the micro-organisms are infectious. Accidents during centrifugation or handling of dried cultures caused extensive contamination of the laboratory. Practically every manipulation in the microbiological laboratory creates aerosols, and these aerosols are probably the source of many laboratory infections.

Corrective Measures

Bacteriological Cabinets

Protection from infectious particles disseminated into the environment surrounding their source may be afforded by a bacteriological safety cabinet, a modification of the hood or

Figure 1. This cabinet may be used without the glove-port panel when small amounts of aerosol are expected.

dry box used for chemical and radiological studies. All potentially infectious operations are thus carried out behind a plane of glass with ventilation sweeping contaminated air away from the technician. When the cabinet is to be used will depend upon the organism, the technique, the skill and immunity of the technician, the seriousness of the possible illness and its possible sequelae, and the relative isolation of the laboratory. A cabinet system is also advisable when there is potential repeated inhalation of large volumes of non-pathogenic micro-organisms. These occasionally cause hypersensitivity (11). Hypersensitivity is also known to develop during the repeated preparation of tuberculin and brucellergen. Nonpathogens have been reported to cause infection in man (12).

The bacteriological safety cabinet (13, 14) may be simple (fig. 1) or elaborate (fig. 2), depending on the need. When there is a large volume of work, special cabinets are justified for particularly hazardous equipment such as the centrifuge and shaking machines (figs. 3

and 4). Ultraviolet light provides partial disinfection of the cabinet interior; sterilization is best accomplished with steam formaldehyde.

Contaminated cabinet air may be filtered through a bacterial filter or piped directly to some sort of air incinerator. An electric grid

Figure 2. Modular gas-tight cabinet system—animal holding, all-purpose, and autopsy cabinets.

Figure 3. This centrifuge cabinet may alternatively be used as a bacteriological work cabinet.

Figure 4. Model of shaking machine-incubator cabinet which may be used to house various types of apparatus.

incinerator (4) has been in use at the National Institutes of Health, Public Health Service, for some time. The efficiency of this incinerator has been reported (15). Individually designed gas or oil fired incinerators are useful for larger volumes of air. Sterilization before renewal or examination of the filter may be accomplished by incorporated electric strip heaters.

The Centrifuge

For most laboratories, adequate centrifuge safety is possible by use of commercially available screw-capped, safety cups for the swinging head. The angle head in a refrigerated or nonrefrigerated centrifuge has required special attention; a new head has been designed with enlarged recesses to hold the safety cups and will soon be available (B). These cups should be filled and opened in a safety cabinet.

Animals and Cages

Experimentally infected animals can be a source of infectious aerosols (16). Such animals are more safely housed in cages with solid bottoms and sides than in wire cages. A simple method for minimizing dissemination of infectious material is equipping cage racks with ultraviolet fixtures (fig. 5). It has been found that when these are adjusted so as to bathe the area immediately above the cage tops with con-

tinuous ultraviolet radiation at an intensity of about 250 microwatts per sq. cm. no viable vegetative organisms escape from the cages. A more expensive method uses ventilated cages in which all input and exhaust air is filtered (fig. 6).

Depending upon the animal, route of inoculation, cage, bedding, and the micro-organism, the accidental aerosol may not only be a hazard to the technician but may peril the validity of an experiment through cross inoculation of ani-

Figure 5. Ultraviolet screen across cage tops prevents escape of viable vegetative cells.

Figure 6. Filtered air is supplied to individual cages connected to negative pressure manifold.

mals or augmentation of the test inoculation (16). In some instances, it has become necessary to cage animals individually to insure the validity of an experiment. Before disturbing the debris or cleaning, cages should be disinfected or sterilized, depending upon the infectiousness of the organism.

The Pipette

The pipette is a significant source of infection, more because of aspiration of liquid than because of inhalation of aerosol. To eliminate the possibility of aspiration and oral contamination, a pipetting device of some kind is desirable (17). There are many pipetting devices which are commercially available, for instance, the aba (C), Adams (D), and Kadavy (E) micropipettors and the aba (C), Caulfield (F), and Fisher (G) pipettors. A new pipetting device which has found favor with the Fort Detrick personnel is the Propipette (H). A simple pipettor can be constructed from a short piece of rubber tubing, or a rubber bulb, such as those used to operate medicine droppers, may be used.

For a pipetting device to be suitable for handling infectious materials outside a safety cabinet, it should not deliver its liquid by forceful ejection, which may produce aerosols. Gravity flow delivery is given by the Caulfield pipettor and the Propipette but not by the other devices mentioned. Contaminated pipettes should be placed in a tray large enough to allow their complete horizontal immersion under a layer of germicidal solution, and the tray should be autoclaved before removing the pipettes.

Other Equipment

The infectious hazards associated with the use of high-speed mixing bowls have been investigated (5). It was found that bacterial aerosols may be set free by (a) a loose fitting cover, (b) lack of a gasket in a tight fitting cover, and (c) a worn bearing or loosely fastened drive shaft. Aerosols are also liberated during removal of blended materials from the bowls. A leakproof blender bowl has been developed and may be commercially available in the future (5, 16).

Aerosols formed by the process of decavitation during operation of the sonic oscillator

may escape through a loosely fitting cover when the contents are removed from the sump. Use of a larger size O-ring (No. 24) generally give adequate closure, while modification of the cover to allow for insertion of a rubber diaphragm so that the contents may be removed by syringe and needle, provides safe removal of contents. Due to the hazard involved, however, it is best to use a blender or a bacterial sonic disintegrator in a safety cabinet.

Clothing

It is advisable to wear suitable laboratory clothing in infectious disease laboratories. The long-sleeve, operating gown which ties in the back and is worn over duck trousers is suitable for men, while a smock may be worn by women. A pair of shoes should be reserved for use in the laboratory only. Wearing a surgical cap may be desirable in animal rooms, when showers do not include the hair or when respiratory protective apparatus is used. Preferably, street clothing should not be worn beneath laboratory clothing, since the former may become contaminated if a spill occurs. Infection of laundry workers has proved that it is necessary to autoclave laboratory clothing of personnel working with some infectious agents (19).

Personal cleanliness is an important barrier to infection. Locker rooms should be equipped so that showers may be taken in case of accidental exposure to infectious materials or at the end of the working day. A germicidal soap containing Hexachlorophene is recommended.

Ventilation

Except in congested areas and with highly infectious agents, sterilization of building exhaust air is of slight importance to the nearby nonbacteriological areas if air from the bacteriological safety cabinets is sterilized. Long experience with this installation has shown (a) that during weeks and months when the exhaust air sterilization system of the general laboratory building was accidentally inoperative (but the cabinet exhaust air was being sterilized), there was no infection of the laboratory personnel or of passers-by and (b) that it is extremely difficult to maintain consistently an air-flow

control such that no potentially contaminated room air escapes into an adjoining "clean area." Proper control of air at the immediate work site may reduce or eliminate the need for exhaust air filtration of the whole building. It should be pointed out that sometimes treatment of air is necessary for public relations or legal reasons. But for the technician, the most important source of infection is within 12 inches of his nose.

Education

Equipping a laboratory with the finest safety devices does not insure against all possible laboratory infections. Equipment is no substitute for safe technique, which is based upon active participation by the worker at the laboratory bench in the process of establishing safe practices. All employees, new and old, should receive safety orientation and training. Supervisors and senior personnel must accept the responsibility for training new personnel and for insisting upon safe practices. A safety manual is an excellent medium for disseminating pertinent information. In our laboratories we have found that the establishment of a laboratory safety council has increased cooperation and facilitated an exchange of ideas. A tangible public award for a good safety record is always an incentive.

Changing the Priorities in Public Health

By GEORGE JAMES, M.D., M.P.H.

THE HEALTH OFFICER is often asked to describe his formula for starting new programs and getting rid of old unproductive ones. This chapter in the art of public health includes more than program development and is considered here under the broader heading, "Changing the Priorities in Public Health." During this era of rapid change in program content, health officers are forced to employ this art to an unusual degree. The present discussion is offered with the hope that some public health practitioners may be aided by statements that reduce their daily problems to simple generalizations which have "deductive fertility."

Criteria for Determining a Priority

The establishment of priority is one of the major responsibilities of the health officer and provides tangible evidence of his capacity for leadership (1, 2). Before giving consideration to changing priorities, it would be well to list some of the criteria for establishing them.

Dr. James is director of health, Akron City Health Department, Akron, Ohio. He began his public health career in 1942 as assistant health officer in Williamson County, Tenn. In 1945, he began a decade of service with the New York State Department of Health and was serving as assistant commissioner for program development and evaluation prior to his present assignment. In addition, he has taught at the Yale University School of Medicine, Johns Hopkins School of Hygiene and Public Health, and the Albany Medical College of Union University. He presented this paper at the annual meeting of the Oklahoma Public Health Association, held November 9, 1955, at Stillwater.

Those listed below are suggested in part by Ascher (3, 4) and are illustrated by examples from the public health field.

Urgency. There is no doubt that the health problems created by a smallpox outbreak or a flood deserve top priority. A breakdown in one of our major barriers against communicable disease, or a mass debacle of any kind, must receive our immediate attention.

Feasibility. Often a program could be readily undertaken with existing resources if a slight amount of effort were added. The teaching of self-breast palpation to middle-aged women by public health nurses can be given priority as part of each visit to a new family under the generalized public health nursing program. Similarly, the use of the tuberculosis mass chest X-ray survey for the detection of heart disease is another example of an extra dividend program.

Scope. Will the program be of benefit to a significant number of citizens or only a few? Will it be countywide or only of value to one small area? It is obvious, for example, that higher priority will be given to a health education program on the early signs of cancer than one on muscular dystrophy.

Preparation for something more extensive. Dr. Ascher calls this the "multiplier effect." Some communities have developed a mobile physiotherapy unit to give simple treatments to home-bound patients with arthritis. This is deemed worthy of priority, since it is probably the first step in a more elaborate program of home care and rehabilitation for all varieties of chronic illness.

Coordination between existing programs. Several communities have invested heavily in programs of slum clearance and construction of low cost housing. Health units in these

areas can gear their environmental sanitation activities to make the total program more effective. The health officer is often able to provide the cement which integrates the vital community programs of other agencies. Many examples of this can be found in existing air pollution, hospital planning, and mental health programs.

Practicality. This is the old concept of efficiency. When the expected return on a small program investment is very great, it becomes a practical matter to give that program a high priority. In this category one can place fluoridation of the public water supply, since at an annual cost of about 10 cents per capita a two-thirds reduction in dental caries among children can eventually be achieved. Another example is the allocation of official funds for the treatment of cases of ringworm of the scalp because of the far greater community cost of the uncontrolled spread of this disease among school children.

Special ability or special mandate. By virtue of its unique skill or legal powers the health department is often the only one or the one best able to perform a particular service. The collection, tabulation, and analysis of morbidity and mortality data, the performance of health services for school children, and the development of inservice medical care programs in municipal government have fallen to the lot of some health officers. It would usually be impossible for a community to develop effective programs in these fields should the health officer fail to give them priority.

Good will. The performance of adequate health programs requires a background of community good will and support. Practically every health officer has, on occasion, given high priority to programs of low health importance as a matter of sound public relations. To avoid later confusion, the health officer should openly admit that the chief objective of such a health program is the enhancement of good public relations if that is the fact.

Changing the Priorities

The development of any health program requires attention to certain strategic factors in the community. With respect to any one pro-

gram, these factors are favorable or unfavorable to some degree. If entirely favorable, active service may begin immediately; if unfavorable, various subsidiary developmental steps must precede the large-scale program.

The physician who performed a "Smithwick" operation for the hypertensive disease of an influential State legislator was in a favorable position to promote a State hypertension commission. The availability of Federal funds for State industrial hygiene services during World War II resulted in the development of such divisions in the States that had not yet established them. Support for special case-finding programs among hospital admissions by local tuberculosis associations has sold these services to many communities.

The health officer who always waits patiently for the time when strategic factors become favorable can be said to be selecting his priorities on the basis of passive opportunism, that is, priority is given to something dramatic and successful, not necessarily that which is most needed to meet local problems. Such a health officer looks for and pounces upon the health angle of any general project that catches the community's fancy. This evokes that comparison between a statesman and a technician in public health (5), which may be applied to the opportunist. The opportunist in public health pursues fleeting, short-term, popular goals which are dramatic and sure of success; the statesman is not reluctant to lend his prestige to the struggle for those long-range goals which are greatly needed although temporarily neither popular nor feasible.

Lest one be tempted to develop a universal dislike for the public health opportunist, let him be advised quickly to correct that impression. Many of our excellent health programs in child health, medical rehabilitation, and research in chronic disease, owe their origin to a unique and happy combination of local factors. In fact, a health officer should be criticized for not taking advantage of such good fortune. Rather must the test of the practice of passive opportunism come from two other questions:

Having once seized the opportunity, has the health officer proceeded methodically and scientifically to build a firm and successful program, or has he dropped this one for the next fair

prospect which loomed into his jurisdictional field?

Is his total program a conglomerate of activities which arrived opportunely, or has he left his impact upon the field of public health practice through programs developed with a greater sense of his own responsibility for determination of priority?

The health officer of today expects to develop programs even when local strategic factors are not quite satisfactory. This chapter on the art of public health practice is the crux of our current task in the establishment of useful programs against the chronic degenerative diseases and accidents. Several examples will be considered to illustrate how priorities can be changed in the absence of perfection in local strategic factors.

The active opportunist. A health officer can act the opportunist even if there are no current opportunities. This might be dubbed "the program plan approach." This health officer sets many irons in the fire. When one of them gets hot, he steps in quickly and forges his program along the lines already planned. Instead of forcing a public reaction, the health officer needs merely wait for public opinion to force the program, which will be any of those he has been holding in readiness.

The danger of such an approach is, of course, that full many an excellent program may be "born to blush unseen." The health literature is replete with excellent program plans which read well but recount only an idea, not a blueprint for action which was effectively taken. After all, how does one judge a program plan which has never been translated into action?

Again, let the reader be assured that there need be no invidiousness attached to this technique of changing priorities. In fact, it is to be highly recommended for those programs which reason tells us are due for the touch of Midas. Health officers would do well to plan thoroughly in the field of adult rehabilitation, home care, radiological health, and mental health. Yet, once having planned, should we not do something more with our script than file it away until D-Day? If not, is there not the distinct danger that some other agency, presumably less well qualified than the trained health department, will seize the initiative be-

cause it happens to be more available to certain newly developing strategic factors?

The demonstration. Long an honored approach to the changing of priorities, the demonstration is usually characterized by its heavy accent on quality service. Less well recognized is the fact that the demonstration should be used only when the health officer is sure of his scientific and practical grounds. A demonstration, it should be remembered, can also be taken by our critics as proof that something cannot be done.

In developing the project, care should be taken to bite off no more than can be thoroughly chewed. If you are planning a complete and integrated school health demonstration program, do not try to establish it in your entire district. One census tract, one school, or even one classroom may be all you can handle effectively without compromising quality. The demonstration team must be overstaffed; later on is time enough to prove we can do the job or the major part of the job with less expense and personnel. Public relations skill is required and care must be exercised. The population involved can learn to consider themselves unhappily as guinea pigs, or with good public education, as those fortunate few who are privileged to receive the first chance to participate in an excellent program.

The demonstration approach is useful today for diabetes detection programs, heart disease detection by mass survey, prophylactic treatment of cases of rheumatic fever, and tumor diagnostic clinics. It, perhaps, should not yet be used for obesity control, which still seems to be based upon too much scientific conjecture to be predictable.

The research approach. The research project differs from the demonstration in one major respect: Its scientific basis is not yet considered proved. In fact, the central idea of establishing the project is to discover more scientific evidence, although it may also render good service to the study population. Our welfare colleagues have coined the term "service-linked research" as a fitting description of this method of program development (6).

The Albany Cardiovascular Health Center (7, 8) is a good example of this technique of changing priorities. The State civil service's

male population between the ages of 40 and 54 are receiving a complete periodic cardiovascular evaluation under a project established by the New York State Department of Health. Not only is this project stimulating fundamental research among the team who are members of the staff of the Albany Medical College or the State Health Department, but it is also aimed at:

- Evaluating the validity and reliability of techniques for the early diagnosis of coronary heart disease and hypertension.

- Stimulating an interest in heart disease among the staff of this State health department and encouraging them to add heart disease studies and related projects to their own specific programs.

- Giving the best in heart disease detection services to a "susceptible" population.

Similar projects are under way with respect to the study of highway accidents (9), prevention of first attacks of rheumatic fever among school children (10), and home accidents (11) in certain areas. At times this technique is used to iron out the administrative features of a program based upon fairly sound scientific principles. The term, pilot project, is commonly, but not exclusively, associated with this use. Such projects do not necessarily require the firm scientific base of a demonstration project.

The get-ready approach. Realizing that he wishes to reach a distant, still unattainable goal, the health officer may undertake a minor program which has a great multiplier effect. This brings him much nearer to coming to grips with the major problem.

In New York State, a program of control of shoe-fitting fluoroscopes was used as the first step in a complete program in radiological health (12). Noting the increasing scope of the problem of ionizing radiation, the department found that the relatively simple task of surveying and correcting the defective units among its 400 shoe-fitting fluoroscopes gave it the opportunity to:

- Acquire much data on the practical risks of ionizing radiation.

- Obtain equipment needed for radiological surveys.

- Stimulate citizen and staff interest in the problem.

- Develop inservice training, both academic and practical, for local health officers and sanitary engineers.

- Develop an extensive program plan, get additional staff, and obtain passage of a complete sanitary code chapter on radiological health.

The advisory committee. A problem such as radiological health, which touches many highly skilled professions, should be approached with the most expert advice. The available data must not only be accurate; it must be correctly interpreted. The implications of various control procedures must be appreciated and endorsed by the technical groups which are concerned. An advisory committee of leaders in these fields is essential.

The use of an advisory committee implies certain specific cautions over and beyond the obvious one of obtaining the proper personnel to serve:

- Do as much work as you can before they convene. You cannot afford false starts. These are usually busy people who cannot take the time to teach you fundamentals. Study the field well, send someone away for a special course if it is unfamiliar, and consult in advance with a key member of the committee to be sure you are on the right track.

- Send the material to be considered to each member well in advance, indicating your sources of information, and if possible, areas of special discussion and decision.

- If the group changes the first draft materially be sure that each has an opportunity to review and comment on the final draft.

The technique of the advisory committee has worked unusually well with new programs based upon the self-policing of special groups. Besides its use in radiological health, a State has found it of value in developing a program involving the labeling of household products which may be hazardous if improperly used (13). It has had an excellent trial in several areas for the development of programs of disaster control. Some health departments are now adopting the plan as a practical step toward good public relations in administration by having advisory committees of prominent citizens help define community needs and promote solutions.

The joint approach. Often a health officer can accomplish much by coordinating his efforts with those of another agency. His added increment of resources, though slight, may be precisely what is needed to make a worthwhile program a reality. At present, it is possible to work with cancer societies for the development of cancer registers, to tie diabetes surveys in with tuberculosis society mass X-ray programs, and to engage in rheumatic fever prophylaxis programs with heart associations.

In the use of this technique, the health officer is urged to spell out the details of the arrangement in writing. Such problems as the duration of the program, the extent of its evaluation, the next steps, the implications to other programs, are well worth some thought in advance. No health officer should permit his complete program to bog down due to firm, long-range commitments made to so many agencies that he has ended by relinquishing all rights to the determination of priority.

The advance on many fronts. Some health officers like to establish a balanced program of new activities; they insist upon having some entry that can be made under each category of public health activity. When something new arises, they do something about it, even if it is on a small scale. This is not a demonstration, not a well-planned approach, not research, not a pilot project, merely something to permit him to dabble lightly in a large variety of services.

If one mentions adult rehabilitation, this health officer reminds us that his public health nurses are following and attempting to return a few hemiplegics to self-sufficiency. If we bring up multiple screening, he has done some hemoglobin and diabetes tests at a county fair. If we mention home accidents, he had his statistician make a 2-month tabulation of patients treated at the emergency room of the local hospital and had a public health nurse follow up on a few of them.

Such public health dilettantism is not necessarily bad. It can be a good first step toward something better and, when this occurs, leads to the concept that there are really no new programs in public health, only changes in emphasis. Best of all, it is often the only way to cajole a reluctant staff. You can sell the care of Mrs. Fred Smith to a nursing division too

busy to accept a "program" in adult rehabilitation. You can get a sanitarian to check the lighting in an apartment hallway when the explanation of your plans for a sanitation home-accident program falls on deaf ears. Using this oblique approach, one can get a community to accept a worthwhile cancer program even before it realizes that something new had been added.

Unloading the Old Program

Since there are, to put it mildly, limitations to the resources available to local health officers, the addition of new programs means that "something's got to give." Health officers fear, and rightly so, to end programs precipitously. Such action may lead to a general feeling of impermanence and consequent lack of fervid local support toward public health programs. Nevertheless, old programs can be dropped under one of several methods:

Changing the character or purpose. The mass chest X-ray for tuberculosis will probably be used increasingly for heart disease and lung cancer detection while its original purpose declines in importance. The female clientele of a venereal disease clinic are easily available for cancer detection, particularly advisable since syphilis (14) and neglected cervicitis (15) are both considered to be precancerous lesions.

The knife. The development of modern knowledge about communicable disease control has permitted drastic changes in quarantine regulations and the free distribution of certain antitoxic serums. Occasionally, when available funds have been curtailed, health officers have found it feasible to do this (16).

Demonstration in reverse. A real challenge awaits local health officers who would like to explore methods of streamlining some of our traditional health programs. Evaluation studies on the details of pasteurized milk inspection, water and sewage plant inspections, and some of the routines of school health practice might prove that much current effort could be curtailed. Perhaps better, quick-screening techniques could be employed to give warning of those places or persons requiring detailed individual attention. Such demonstration in reverse, in the sense that it shows how the efficiency of our programs may be improved by

curtailment, should result in the saving of effort which can then be diverted to more valuable services.

Plus-minus method. This method can also be called "accentuating the positive." By so doing, attention is drawn away from the unnecessary so that it can be de-emphasized. In milk-production control, one can accent cooling, clean equipment, and cow health, and allow cracks on the floor, area of window space, and certain required partitions to acquire less significance. Greater attention in cancer control can be given in some areas to teaching individual physicians how to perform cancer diagnosis rather than continue to multiply the number of expensive cancer detection clinics. In school health, the development of strong programs of teacher-nurse-parent conferences will draw attention away from unproductive, routine morning clinics.

Gradual attrition. Old programs which refuse to die might eventually fade away. County health units which have practiced rigid quarantine for certain common communicable diseases may hesitate to suggest a drastic change in keeping with modern control regulations. There is always the fear that any de-emphasis in control may spread to other disease programs. By avoiding all attempts at stimulating this particular program it can slowly wither until the community is better prepared to take a definite stand at modernizing quarantine regulations.

Summary and Conclusion

This discussion seeks to explore a small chapter in the art of public health practice dealing with the ways in which health officers add new services to their entire community health programs. Some of the criteria for the determination of priority are listed and certain principles presented to indicate how these priorities are changed. Examples of the development of new programs and de-emphasis of others are discussed. In general, we require two things of the modern health officer:

- Many individual approaches to public health practice.
- Precise and adequate communication on the plans and results of these practices.

From the mutual stimulation following the

defense of his activities before a jury of his peers will come progress not only in the science of preventive medicine but in the health officer's own very special art of public health practice.

Jones Criteria (Modified) for Guidance in the Diagnosis of Rheumatic Fever

RHEUMATIC FEVER is related to previous infection with group A beta hemolytic streptococcus, but the mechanism of the disease is unknown. Its boundaries are indefinite, and its differentiation from other diseases is sometimes impossible. There is no specific laboratory diagnostic test. The diagnosis must therefore be arbitrary and empirical. Criteria herein set forth are aimed at identifying those individuals who have had or are having an attack of rheumatic fever. They make no attempt to measure rheumatic activity at any given time or to diagnose inactive rheumatic heart disease. Thus, following the designation of an illness as rheumatic fever, the existence of continued activity or the presence of inactive rheumatic heart disease may be indicated by criteria different from those outlined below.

Criteria are necessary in order to minimize both overdiagnosis and underdiagnosis. The tendency to label as rheumatic fever a chronic febrile illness for which no obvious cause can be found is to be deplored. The tragedy which may lie in the wake of the false diagnosis of rheumatic fever may be even greater than the possible harm of missed recognition in questionable cases. The institution of effective

prophylactic regimens requiring prolonged administration of sulfadiazine or antibiotic agents places a grave responsibility on the physician in the diagnosis of this illness.

In this statement, the diagnostic features of the disease are divided as originally proposed by Jones into major and minor categories dependent upon their relative occurrence in rheumatic fever and in other disease syndromes from which this disease must be differentiated. Thus chorea is included among the major criteria while fever, a symptom common to many diseases, is placed in a minor category. These major and minor categories have no significance beyond their diagnostic import either as to prognosis, amount of "rheumatic activity," or severity of acute illness. Indeed, a severe manifestation of rheumatic fever such as rheumatic pneumonia is not included because it is difficult to differentiate from congestive cardiac failure and because it almost always occurs in patients whose rheumatic fever is so obvious as to offer no difficulty in diagnosis.

The presence of two major criteria or one major and two minor criteria indicates a high probability of the presence of rheumatic fever with one notable exception (see "other manifestations"). In addition to the major and minor criteria to be used in the recommended formula, other manifestations have been listed which may be used to support the diagnosis. These criteria are not meant to substitute for the wisdom and judgment of the clinician. They are designed only to guide him toward a diagnosis of the disease with the suggestion that he follow carefully all questionable cases and restrict the diagnosis of rheumatic fever to illnesses which meet acceptable criteria.

This report of the Committee on Standards and Criteria for Programs of Care of the Council on Rheumatic Fever and Congenital Heart Disease of the American Heart Association has been approved by the executive committee of that council. The original report was published in "Modern Concepts of Cardiovascular Disease," vol. 24, September 1955. In revised form, it is being given wide circulation to support efforts to detect and treat rheumatic fever.

Major Diagnostic Criteria

Carditis

Murmurs. The presence of a significant apical systolic murmur, apical mid-diastolic murmur, or basal diastolic murmur in an individual without a history of previous rheumatic fever or in whom there is good reason to believe there was no pre-existing rheumatic heart disease; or a change in the character of any of these murmurs under observation in an individual with a history of rheumatic fever or rheumatic heart disease.

Increasing Cardiac Enlargement. Obviously increasing cardiac enlargement by X-ray.

Pericarditis. Pericarditis manifested by a friction rub, pericardial effusion, or definite electrocardiographic evidence.

Congestive Failure. Congestive heart failure (in a child or young adult under 25) in the absence of other causes.

Polyarthritis

Polyarthritis tends to be migratory and is manifested by pain and limitation of active motion, or by tenderness, heat, redness or swelling of two or more joints. Arthralgia alone without objective evidence of joint involvement is not a major manifestation.

Chorea

This must be differentiated from habit spasm, athetosis, and cerebellar ataxia. Movements must be characteristic, involuntary and of moderate severity if chorea is to be used as a major manifestation.

Subcutaneous Nodules

These are shot-like, hard bodies seen or felt over the extensor surface of certain joints, particularly elbows, knees and wrists, in the occipital region, or over the spinous processes of the thoracic and lumbar vertebrae.

Erythema Marginatum

This recurrent, pink, characteristic rash of rheumatic fever, in which the color gradually fades away from its sharp scalloped edge, is found mainly over the trunk, sometimes on the extremities, but not on the face. It is transient, is brought out by heat and migrates from place to place.

Background

In 1944, the late Dr. T. Duckett Jones published criteria for the diagnosis of rheumatic fever which have been generally accepted in the United States and in many parts of the world. Subsequently Dr. Jones guided the revision of his criteria for use in the United Kingdom-United States Cooperative Study on "The Relative Effectiveness of ACTH, Cortisone and Aspirin in the Treatment of Rheumatic Fever," and, just prior to his death, he participated in a conference on the revision of his original suggestions for use by the practicing physician. These modified Jones criteria are based in great measure upon his suggestions.

Minor Diagnostic Criteria

Fever

A significant rise in temperature is a common symptom, but, because it occurs in so many illnesses, it has little differential diagnostic value. In order to be included, the elevation in temperature must clearly exceed the normal diurnal fluctuation in which there is great individual variation.

Arthralgia

Pain clearly located without objective findings is only a minor criterion for diagnosis. The pain must be in the joint, not in the muscles or other periarticular tissues, and must be distinguished from the nocturnal pain in the extremities occurring in normal children. Arthralgia must not be used as a minor criterion when polyarthritis is included as a major criterion.

Prolonged P-R Interval in the Electrocardiogram

Prolongation of the P-R interval may be nonspecific; it is considered a minor criterion and is not diagnostic of carditis. It cannot be used if carditis is already included as a major manifestation.

Increased Erythrocyte Sedimentation Rate, Presence of C-Reactive Protein, or Leukocytosis

Elevation in one or more of these nonspecific tests may be considered as a single minor cri-

Jones Criteria (Modified) for Guidance in the Diagnosis of Rheumatic Fever

RHEUMATIC FEVER is related to previous infection with group A beta hemolytic streptococcus, but the mechanism of the disease is unknown. Its boundaries are indefinite, and its differentiation from other diseases is sometimes impossible. There is no specific laboratory diagnostic test. The diagnosis must therefore be arbitrary and empirical. Criteria herein set forth are aimed at identifying those individuals who have had or are having an attack of rheumatic fever. They make no attempt to measure rheumatic activity at any given time or to diagnose inactive rheumatic heart disease. Thus, following the designation of an illness as rheumatic fever, the existence of continued activity or the presence of inactive rheumatic heart disease may be indicated by criteria different from those outlined below.

Criteria are necessary in order to minimize both overdiagnosis and underdiagnosis. The tendency to label as rheumatic fever a chronic febrile illness for which no obvious cause can be found is to be deplored. The tragedy which may lie in the wake of the false diagnosis of rheumatic fever may be even greater than the possible harm of missed recognition in questionable cases. The institution of effective

prophylactic regimens requiring prolonged administration of sulfadiazine or antibiotic agents places a grave responsibility on the physician in the diagnosis of this illness.

In this statement, the diagnostic features of the disease are divided as originally proposed by Jones into major and minor categories dependent upon their relative occurrence in rheumatic fever and in other disease syndromes from which this disease must be differentiated. Thus chorea is included among the major criteria while fever, a symptom common to many diseases, is placed in a minor category. These major and minor categories have no significance beyond their diagnostic import either as to prognosis, amount of "rheumatic activity," or severity of acute illness. Indeed, a severe manifestation of rheumatic fever such as rheumatic pneumonia is not included because it is difficult to differentiate from congestive cardiac failure and because it almost always occurs in patients whose rheumatic fever is so obvious as to offer no difficulty in diagnosis.

The presence of two major criteria or one major and two minor criteria indicates a high probability of the presence of rheumatic fever with one notable exception (see "other manifestations"). In addition to the major and minor criteria to be used in the recommended formula, other manifestations have been listed which may be used to support the diagnosis. These criteria are not meant to substitute for the wisdom and judgment of the clinician. They are designed only to guide him toward a diagnosis of the disease with the suggestion that he follow carefully all questionable cases and restrict the diagnosis of rheumatic fever to illnesses which meet acceptable criteria.

This report of the Committee on Standards and Criteria for Programs of Care of the Council on Rheumatic Fever and Congenital Heart Disease of the American Heart Association has been approved by the executive committee of that council. The original report was published in "Modern Concepts of Cardiovascular Disease," vol. 24, September 1955. NATIONAL HEALTH FORUM

chronic illness

THE National Health Forum is conducted each year by the National Health Council to consider a currently pressing health problem. This year the problem was the mounting "daily disaster" of chronic illness.

Because of the wide concern over the magnitude of chronic illness, 800 health leaders attended the 2-day session of the forum in New York City, March 21 and 22, 1956. They came from the 50 national organizations which are the active, advisory, associate, and sustaining members of the National Health Council, from 35 additional national organizations, and from many State and local groups.

Forum participants heard Leonard W. Mayo, chairman of the Commission on Chronic Illness and director of the Association for the Aid of Crippled Children, in the keynote address, say that chronic diseases account for 88 percent of all disabling conditions in the United States.

Chief speaker at the closing dinner, March 22, was Dr. Lowell T. Coggeshall, recently appointed Assistant Secretary for Health and Medical Affairs, Department of Health, Education, and Welfare.

The address of Mr. Mayo on the problem and the challenge of chronic illness, and Dr. Coggeshall's answers to the challenge plus seven other papers from the forum are presented in brief on the following pages.

"Chronic illness accounts for almost three-fourths of the Nation's daily sickness toll," said President Dwight D. Eisenhower in a telegram read at the opening session by Hugh R. Leavell, M.D., president of the National Health Council. The President's message continued:

"There is urgent need both for more research into such disease and for prompt and widespread application of existing knowledge. For their continuing effort to solve this health problem of vital concern to our Nation, I congratulate the agencies represented in the National Health Council."

In an introductory speech, the chairman of the forum, Theodore G. Klumpp, M.D., who is president of Winthrop Laboratories, described the forum as essentially an effort to discover the type of "gears" needed to meet the new health care demands created by the predominance of chronic illness and how best to "shift" into them. He said the forum's task lay in the realm of human engineering.

"People and institutions are finding it hard to shift gears fast enough to keep pace with the changes that new scientific discoveries are making in the methods by which we may preserve or regain health among people of all ages," he stated.

terion. Particularly to be deplored is the tendency to use any of these tests as a major criterion or as diagnostic of rheumatic fever. There are many other nonspecific tests, but these three are most commonly used.

Evidence of Preceding Beta Hemolytic Streptococcal Infection

This must be documented by (1) a history of scarlet fever or by a typical clinical picture of other streptococcal infection preceding the onset of rheumatic fever by one week to one month, the nature of the infection being confirmed by a history of immediate contact with other individuals having typical streptococcal infection or by positive culture of the nose or throat in which beta hemolytic streptococcus predominates; or (2) an elevated or rising anti-streptolysin-O titer.

Previous History of Rheumatic Fever or the Presence of Inactive Rheumatic Heart Disease

The existence of either of these may be used as a minor criterion to aid in deciding the rheumatic nature of the illness in question. For this use, the previous history must be documented by the same objective criteria as are set forth in this statement or by the presence of inactive rheumatic heart disease.

Other Manifestations

These include systemic manifestations such as loss of weight, easy fatigability, elevated sleeping pulse rate (tachycardia out of proportion to fever), malaise, sweating, pallor or anemia, and local manifestations such as epis-taxis, erythema nodosum, precordial pain, abdominal pain, headache, and vomiting. These, as well as a family history of rheumatic fever, provide additional evidence of the presence of rheumatic fever but are not to be included as diagnostic criteria.

There are combinations of these diagnostic criteria which occur in the presence of other illnesses which must be ruled out before a definitive diagnosis is made. One combination in particular—polyarthritides, fever, and elevated sedimentation rate—is the weakest of all combinations of major and minor criteria. Diseases to be ruled out include rheumatoid arthritis,

gonococcal arthritis, lupus erythematosus disseminatus, subacute bacterial endocarditis, non-specific pericarditis with effusion, leukemia, sickle cell anemia, serum sickness (including manifestations of penicillin sensitivity), tuberculosis, poliomyelitis, undulant fever, and septemicias, particularly meningococcemia.

Murmurs Indicating Carditis

Significant Apical Systolic Murmur

A significant apical systolic murmur is long, filling most of systole; is heard best at the apex; is as well transmitted toward the axilla as over the precordium; and does not change with position or respiration. It must be differentiated from an innocent (functional) murmur which is frequently found in normal people. This innocent murmur is systolic, occasionally harsh, is heard best along the left sternal border and usually changes with position and respiration. Borderline systolic murmurs, intermediate in location and nature, occur and should be carefully watched. Questionable murmurs which are intermittently present or which, after a period of observation, cannot be clearly classified as significant are rarely of any import.

Apical Mid-Diastolic Murmur

A significant organic apical systolic murmur is frequently accompanied by a low-pitched, short mid-diastolic murmur which is sharply localized to the chest wall over the apex of the heart and often heard best with a patient in the left lateral position with the breath held in expiration. This murmur, rarely present in the absence of an apical systolic murmur, confirms the significant nature of the latter. It must be differentiated from the long, low-pitched, crescendo apical presystolic murmur followed by an accentuated mitral first sound which is indicative of mitral stenosis but not of acute carditis.

Basal Diastolic Murmur

The development of a basal diastolic murmur of aortic insufficiency is also indicative of carditis. It is an early, short, diminuendo murmur usually heard only or heard best along the left sternal border in deep expiration. It has great diagnostic value, even though it may be difficult to hear and present only intermittently.

of these experiences are distilled in the following statements:

- A study of community chronic illness can be an instrument to effective action, but if not wisely planned, it can prove to be an obstacle.

- Participation of physicians in any community program for the chronically ill is of key importance.

- People who cannot understand vague references to "the chronically ill" will listen to specifics; for example, "Mrs. Brown is taking Hope Hospital's homemaker service to old Mr. Attarian each day."

Other panel moderators were Arnold B. Kurlander, M.D., chief, Chronic Disease Program, Public Health Service; Cecil G. Sheps, M.D.,

executive director, Beth Israel Hospital, Boston; George Bugbee, president, Health Information Foundation; G. D. Carlyle Thompson, M.D., executive officer, Montana State Board of Health; and Leona Baumgartner, M.D., New York City health commissioner and incoming president of the National Health Council.

Next year's forum will consider mental health, in its broad implications for all organized health effort. To be held in Cincinnati, March 20-21, it is part of a plan to rotate the annual forums of the council throughout different areas of the United States. Basil O'Connor, president of the National Foundation for Infantile Paralysis, was chosen president-elect of the council.

Symbols of some of the participating organizations of the National Health Council.

"We do not wish to discard any of our human and institutional health care machinery, for we have too little of both, but rather to think of retooling and reassembling where changes may do the most good," he said.

Dr. Klumpp cited estimates of the Commission on Chronic Illness, indicating that 28 million persons in the United States—1 in every 6—suffer from some known physical or mental impairment.

More progress has been made in the conquest of disease and the prolongation of life in the last 50 years than had been accomplished in 999 centuries of man's previous existence, Dr. Klumpp said. Life expectancy has moved upward from 49 years in 1900 to almost 70 years in 1955, and, if the population forecast is correct, he continued, 1 in every 7 persons in 1980 will be 65 years of age or older.

"That means a larger burden of the chronic illnesses, though we shall hope that new medical and surgical advances can cut down the toll," he stated.

"Dealing with the long-term illnesses requires a great deal more community cooperation and more individual initiative and understanding than it took to control the communicable diseases," Dr. Klumpp pointed out.

Recommendations for the retooling which Dr. Klumpp urged were numerous throughout the six panel discussions that made up the major part of the forum. One of the panels sought answers to whether a home care program should be hospital oriented or health department oriented, how much responsibility for the chronically ill the general hospital should assume, how the necessary integration of hospital and home care can be realized.

Two other discussion questions were: Can the total of voluntary (direct and prepaid) and public assistance payments be increased to reduce the balance of unmet needs, with all that they entail of individual suffering and human waste? How can we awaken communities to chronic illness needs? Through service and referral centers? Through studies? Through committee action?

Four priorities seemed to emerge from the

many needs for action on chronic illness brought out in the panel sessions. These may be stated as:

1. Adopting a "do it yourself" approach to health problems in order that all citizens may seek medical aid in the early detection of chronic diseases and cooperate in whatever changeover is required in each community to meet the new challenges presented by long-term diseases and disabilities.

2. Joining more closely the medical and social sciences since the effective medical care of the patient and his cooperation are to be realized only through good community organization.

3. Providing tools to help professionals and the general public understand more acutely the common denominator aspects of chronic illness so that community health services may develop the flexibility and flow requisite to care of the chronically ill.

4. Taking inventory of the sickness in the Nation and what is needed in the way of additional services and planning.

Samples of the forum's advice may be drawn from the experiences reported to the panel on "Community Action Together." The panel was moderated by Charles H. Brasuell, executive director, Pennsylvania Health Council. Three

Coordination of Communication

In the hope of encouraging speakers to say what they really mean, rather than repeat ritualistic phrases or shopworn words which have lost their original market value, one panel agreed that a fine would be levied for what James Thurber has satirized as "the gangrenous repetition of threadbarisms." Specified examples included "cooperate," "integrate," and "coordinate," as well as "area" and "level of action." Fines ranged from 5 cents for abuse of "impact" and 10 cents for "field" to 25 cents for "in terms of." The fine for "integration into the basic health structure" was remitted for a speaker who used the phrase at the right point. Panel members so well voiced their thoughts that receipts were zero.

and enhanced by the presence in the community of adequate treatment facilities. Hospitals, clinics, nursing homes of high standard, and like facilities come only as the direct result of citizen interest and community action.

Of the nearly 5.5 million victims of long-term illness, 2.1 million are 65 years old and over, 1.8 million are between 45 and 65, and 1.4 million are under 45. These figures and the record of the rehabilitation of chronically ill persons should put to rest the common misconception that chronic illness is synonymous with old age and generally incurable. The rate of chronic illness in relation to age is, however, significant. It is 1.3 percent for those under 45, 5.8 percent for those between 45 and 64, and 17.1 percent for those 64 years old and older. Disabling illness is 13 times as great for those 65 years of age and beyond as it is for those under 45.

Principles and Recommendations

The Commission on Chronic Illness has evolved a number of basic principles and a series of recommendations as a result of important studies, fact finding surveys, and research. It is both timely and appropriate to list a few of the most germane.

First, as to the individual patient himself—his needs, his rights, his personality are paramount. His needs cannot be met, nor his rights properly recognized, nor his personality fully respected, however, unless he is treated as a whole person. If he is regarded thus, his rehabilitation or restoration will inevitably include the services of many professions and disciplines.

When more than one profession is involved, there arises the need for wise planning, skillful cooperation, and harmonious interplay among the representatives of each profession. This is, in essence, the team, currently a popular concept but not yet fully understood or too effectively practiced.

In this integrated approach to the treatment of chronic illness, perhaps the strongest factor is our knowledge and treatment of the purely

physical aspects, and the weakest is that of the social and emotional factors. We have considerable security in dealing with the former, but something less than that in dealing with the latter.

Recognition should therefore be given to the importance of the emotional attitude of patients whose illnesses become long drawn out, permanently crippling, or in other ways a major frustration. These attitudes embrace morale, motivation, and mood. Personnel in institutions, in the home, and the patient's family must constantly seek to help the patient endure pain, delay, and disappointment; faithfully follow difficult treatment regimens; keep hope alive; maintain a will to live; and develop a philosophy of acceptance as part of a mature faith.

Care of the chronically ill is inseparable from general medical care. While it presents certain special aspects, it cannot be medically isolated without running serious dangers of deterioration of quality of care and medical stagnation.

Care and prevention are inseparable. The basic approach to chronic disease must be preventive, and prevention is inherent in adequate care of long-term patients.

Rehabilitation is an innate element of adequate care, and the process properly begins with diagnosis. Rehabilitation is applicable alike to persons who may become employable and to those whose only realistic hope may be a higher level of self-care. Not only must formal rehabilitation services be supplied as needed, but programs, institutions, and personnel must be aggressively rehabilitation-minded.

With full appreciation of the necessity for adequate institutional facilities, and with the realization that some areas lacking in such accommodations should provide them, the commission feels that henceforth communities generally should place the greater emphasis on planning for care in and around the home.

Hospitals, outpatient departments, health departments, nursing organizations, and others furnishing the specialized services required by the long-term patient should reexamine their policies and practices to assure for him the best modern medical care.

Five Million People

Chronic illness is the challenge of this era to hospital, public health, medical, nursing, and all the professional services concerned with sickness and disability. It is a golden opportunity in the golden age of medicine.

The challenge of chronic illness is seen in the lives of all those who are adversely affected physically, socially, and economically, and particularly in the lives of the estimated 2 million adults who, though now idle, could become employable and tax paying if provision were made for their rehabilitation. More than 90 percent of these persons could be brought to complete economic self-sufficiency if adequate facilities for rehabilitation were available to them. The Office of Vocational Rehabilitation of the Department of Health, Education, and Welfare has an extended program with this objective in mind.

The problem of chronic illness—much better defined as long-term illness—is illustrated by the hard core of nearly 5½ million people in the United States with chronic disabilities sufficiently serious to require some form of care. It is illustrated daily by the continuing struggle maintained at an appalling cost in dollars, depleted energy, and lives against the cardiovascular diseases, responsible for more than half of the deaths in the country; against cancer, which kills a quarter of a million Americans annually; against mental illness, which brings three-quarters of a million people under

some form of hospital care in the course every 12 months; against arthritis and rheumatism; against blindness and deafness; against epilepsy, tuberculosis, multiple sclerosis, Parkinson's disease, diabetes, cerebral palsy, and various eye disorders. In short, these diseases and handicaps account for 88 percent of all disabling conditions in the United States.

Commission on Chronic Illness

The Commission on Chronic Illness, composed of nearly 50 interested and knowledgeable citizens and some 30 technical assistants, and served by a highly competent staff, was founded in 1950 by the American Medical Association, the American Hospital Association, the American Public Health Association, and the American Public Welfare Association to help define, identify, clarify, and classify the problem of chronic illness.

The commission has defined chronic illness as comprising "all impairments or deviations from normal which have one or more of the following characteristics: are permanent, leave residual disability, are caused by nonreversible pathological alterations, require special training of the patient for rehabilitation, may be expected to require a long period of supervision, observation or care."

The commission was dissolved in June 1956. It therefore remains for other organizations to go forward with extensive programs designed to meet the problems of chronic illness.

—LEONARD W. MAYO

By Leonard W. Mayo, chairman of the Commission on Chronic Illness and director of the Association for the Aid of Crippled Children, New York City, who summarizes in brief the principles and recommendations of the commission, to be published soon in a four-volume edition. A midway report on the work of the commission appeared in the March 1954 issue of Public Health Reports, p. 295.

Chronic illness is no longer the exclusive and private business of the patient and the healing professions. It is a matter of public concern in an age when, for humanitarian reasons and for reasons of defense, the Nation is more conscious than ever before of the need for conserving human resources. In such an age, illness, disability, and preventable death are problems the whole community must comprehend and help solve. The time-honored confidential relationship between the physician and his patient has limited value unless it is supported

of various types of existing resources for care.

- List the kinds of needs represented in a cross section of the people in the town or county who have been ill or handicapped for a period of time—medical, educational, vocational, social needs, and the like—and the kinds of services, facilities, and personnel required to meet such needs somewhere near adequately.

- Determine how a unified program to meet the needs should be financed and administered.

The services and facilities that a typical town or county should expect to develop in about 10 years might be something like the following checklist. It can be adapted to any size community.

A diagnostic, evaluation, and classification center. The center should be located in a hospital if at all possible and should sustain close relations with all hospitals in the area. With the cooperation of the private physicians and hospitals who refer cases to it, the center should provide full diagnostic and evaluation service for the chronically ill and the handicapped.

Counseling and employment service. The service should probably be a part of the diagnostic and evaluation center, though it would be closely related to the board of education and the council of social agencies as well. It would furnish educational, vocational, and employment guidance.

Treatment facilities and services. Every county should have at least the following facilities and services for the benefit of all chronic patients residing in the area.

1. Medical and dental societies interested in the problem of the chronically ill.

2. Adequate public departments of health and hospitals.

3. A program of home care (many chronic patients now in hospitals and nursing homes can be cared for at home with the aid of housekeeper service, public health nurses, and hospital personnel).

4. Licensed nursing homes under public or private auspices or under both and closely related to the hospitals.

5. A private or county hospital or a wing

exclusively for chronic patients requiring hospital care for a protracted period.

6. Home industries and educational programs for persons who can carry on a limited amount of work or study at home.

7. Sheltered workshops and special educational classes for adults, children, and young people who cannot meet the demands of regular employment or school.

Along with these services and facilities, there should be sufficient flexibility and fluidity so that a patient may move from one service to another as his condition changes. Thus, a patient might be referred to the diagnosis and evaluation center, be sent to the hospital for the chronically ill, move on to a nursing home if his condition so indicates, go later to his own home, thence to a sheltered workshop, and finally to regular employment if rehabilitation is relatively complete.

It is this dynamic element or movement quite as much as the accession of needed services and facilities that will mark the community and hospital efforts of the next decade as differing from those we have known.

The costs of such a program will not be entirely met by salvaged lives and earning capacities, and by the elimination of duplicating and unnecessary services. Yet, in due course, citizens will find that under a modern dynamic program the number of persons rehabilitated and returned to full or partial employment will go a long way, over a period of time, toward meeting the extra cost.

The words of Thomas Mann suggest the philosophy that should guide us: "Let us think like men of action, let us act like thoughtful men."

Public Programs

The challenge and the problem of chronic disease and disability concern the entire Department of Health, Education, and Welfare—involving to some extent the Social Security Administration, the Office of Education, the

Adequate care of the long-term patient requires arrangements which promote frequent evaluation of the patient's needs and easy flow back and forth among home, hospital, and related institutions.

Coordination and integration of services and facilities are a must in promoting good care for the chronically ill.

No pattern for organizing services is satisfactory for all communities. Programs must of necessity be tailored to fit local situations, taking full account of what is good in existing resources for care at home or in an institution. Planning should be based on facts—both local and regional—as to needs, density of population, financial capacity, and types of illnesses and accidents likely to prevail.

Planning and programs must be directed to the needs of all long-term patients, and not limited to the needs of any special economic, racial, cultural, or other segment of the population.

Personnel shortages in the professions concerned with the chronically ill constitute a major block to improvement of care. The number of personnel must be increased by recruitment, assistance with the costs of education, attractive salaries, and other inducements. This is particularly applicable to personnel associated with physicians in patient care.

The cost of programs to provide care to long-term patients should be measured first as to human values of effectiveness, then as to productivity. The most economical care is that which returns a person as quickly and as fully as possible to the highest attainable state of health and social effectiveness.

The primary function of philanthropy in financing long-term care should continue to be that of strategic investment of venture capital. Philanthropy should play an important role in financing the coordination of community facilities and should lead the way in the provision of more adequate care through research, demonstration, and experimentation.

Public financing of medical care for long-term indigent and medically indigent patients is inadequate in most communities, whether for long-term or short-term general hospital care, mental and tuberculosis hospital care, nursing-

home care, rehabilitation services, or care at home.

Increased amounts of public and private funds must be devoted to measures to coordinate the services needed by long-term patients.

Private and public expenditures for research should be expanded.

A vigorous program of public education should be launched to stimulate the achievement of the recommendations for financing outlined herewith.

Investigations of diseases and their origins and studies of the needs and responses for maintaining and improving health should command high priority in the spending of research funds. To increase and extend the application of knowledge gained from research, laboratory and clinical investigations must be correlated with intensive and extensive research designed to measure the dimensions of the chronic disease problem and to reveal the most appropriate and effective methods and procedures for meeting those problems.

Checklist for Any Locality

The effective application of these principles, policies, and philosophy to local communities is basic to meeting the challenge of chronic illness in the United States. An area of 100,000 population, for example, may expect to have 3,500 persons needing long-term care. More than three-fourths of these persons are in their own homes, yet they may need some form of help from a community service at some time.

If a community does not have a committee now studying problems of chronic illnesses as a whole, such a committee should be organized. It could be set up on a town or county basis. It should be composed of both professional health leaders and representatives of other professions as well as business, industry, and labor. It should be developed in cooperation with medical and dental societies, the council of social agencies, the health council, and the health department. Three first steps for such a committee would be to:

- Study the total problem of chronic illness in the area and, with the help of a small staff, bring together facts on the extent and character

physical plant now used for medical research was designed or built at the beginning of the century. It is not satisfactory for modern health research.

Even if unlimited sums were suddenly made available for medical research, and satisfactory physical facilities existed in which to conduct expanded research, I doubt that progress could be accelerated in the face of a shortage of adequately trained, properly paid, young people. Too many talented young men and women in the health professions leave teaching assignments, research laboratories, health departments, and hospitals because of financial pressures. Of course, we all recognize that dedication is a prime requisite for a health practitioner. But financial sacrifice need not be an essential requirement for a career in health.

Now, if we have adequate facilities, ample research funds, and sufficient talent, we can make enormous progress by developing a steadily increasing program of basic and clinical research. In my own association with the cancer program over the past few years, primarily as an administrator, my attitude changed gradually from real scepticism to conservative optimism. This change came about largely because scores of the best scientific minds are now attacking the problem with fervor and support. Yet, a few decades ago many talented workers felt that the approaches to basic research in cancer were so unpromising as to hold little hope of solution.

Although full knowledge of the cause of many chronic disease entities appears to be far in the future, substantial progress toward their control is now possible. There must be greater emphasis on efforts to translate present knowledge into improved medical and public health practice. Much more is known about chronic disease and disability than is being applied. We must demonstrate especially that they need not be accepted as inevitable among the older age groups.

Primary preventive techniques, as that term is generally understood in public health, are now feasible for some types of congenital heart disease, for secondary hypertension, syphilitic

heart disease, and rheumatic heart disease. Preventive measures may now also be taken against those forms of cancer in which environmental hazards are believed to be contributory or precipitating as well as against certain precursors of cancer.

Among the neurological disorders, it is already possible to institute primary preventive procedures to control cerebral palsy. Much blindness is preventable. Controlled use of oxygen will prevent retrolental fibroplasia among most premature infants who require this aid. Ophthalmia neonatorum and uveitis are preventable through control of the causative agents. Congenital cataract can be prevented among some patients. Avoiding the use of certain mydriatics during examination of the eyes of older people will prevent glaucoma.

The Steps Forward

It is not unreasonable to ask why, since we know the preventive measures needed, we do not proceed at once to take the actions indicated. It may fairly be said that preventive action against chronic disease is under way already—by millions of people in thousands of communities.

Even the casual newspaper reader or television viewer is aware that syphilis and tuberculosis, are, broadly speaking, preventable. The public is learning that maintenance of desirable body weight will contribute to the prevention of diabetes, hypertension, and heart disease. The increasing popularity of long weekends and vacations would indicate, apart from economic factors, that some notion of proper balance between exertion and rest is spreading. On the other hand, the rate of accidents—on the highway, at work, and at home—would indicate either inadequate educational or preventive efforts or, perhaps, both.

The seriousness of neurological and mental disease is now gaining recognition, in terms of statistical prevalence, economic burden, and human misery. Nearly 1 person in 10 can expect to be hospitalized for a mental illness during his lifetime. Mental patients occupy a little less than half of the Nation's hospital

Office of Vocational Rehabilitation, the Food and Drug Administration, Saint Elizabeths Hospital, as well as the Public Health Service.

Because of a lack of basic data it is impossible to define the magnitude of the problem accurately. Excellent specific studies have been made in a few areas since the last nationwide data were compiled in 1936. But these are all too few, and there is no compilation for the country as a whole. If the proposed continuing, national sampling survey of disease and illness is approved, the Public Health Service will derive statistical estimates of the extent of the major diseases, injuries, and impairments. Estimates will be made of the nature and duration of the resulting disability and of the amount and type of medical and related services received.

Scientific research is fundamental in meeting the problem of chronic disease and disability. Thanks largely to science, the modern physician in a few minutes can accomplish more for a pneumonia patient with a penicillin injection than his professional predecessor could by staying up all night awaiting a crisis.

It is significant that—in spite of the new chemotherapeutic agents and antibiotics, improved diagnosis and surgical techniques, extensive use of blood plasma and parenteral fluids, and the steadily increasing emphasis and effectiveness of preventive medicine—our statistical trend of increasing longevity is not fully maintained after we pass the middle age brackets.

Although there has been some improvement in mortality toward the end of middle life, it has been relatively small, and in old age it has been imperceptible. In the United States the decline in mortality for men over 40 has not kept pace with the corresponding decline for men in Canada, Australia, New Zealand, and in most of the countries of northwest Europe.

By Lowell T. Coggeshall, M.D., Special Assistant for Health and Medical Affairs, Department of Health, Education, and Welfare.

Several explanations have been advanced as to why life expectancy among the older age groups has not increased more rapidly. None has been adequately tested. I will dismiss this subject for the moment with this question: Does the youngster who survives a deadly infection, thanks to an antibiotic, have a lessened tolerance to cancer, heart attack, or some other degenerative disease in later life?

We know that people over 65 have almost twice as many disabling illnesses as those between 16 and 64. Moreover, they respond less rapidly to treatment or care, usually requiring twice as much time for satisfactory response.

Knowledge and Practice

Uppermost in the thinking of the Department has been the fact that the burden of chronic disease and disability falls so heavily on older people. However, we deem it unwise to attempt to limit research to what might be commonly regarded as problems of the upper age groups.

The most important discovery for the health of older patients could well come from a study in pediatrics. More fundamentally, a finding in biochemistry, physiology, or genetics may need only minor variations—or none at all—to be applied to conditions prevalent among patients of a given age.

Through basic and clinical research, progress toward effective treatment of some chronic illnesses has been rapid in recent years. Many patients formerly considered incurable can now be cured or their lives prolonged. Although medical research is making encouraging progress, any attitude other than an aggressive one toward further progress would be inconsistent with our beliefs. We must not make the mistaken assumption, though, that providing unlimited funds will solve any research problem. To the contrary, we must acknowledge that research progress will be limited always by at least three factors: facilities, trained manpower, and, above all, ideas.

Fortunately, private philanthropy and public funds have provided strong financial support for research into many major medical disorders. Unfortunately, however, much of the

voluntary health insurance, especially as it relates to long-term illness.

It is relatively easy to foster understanding of the need for individual protection against the costs of medical and hospital care. It is not simple, however, to elicit lasting motivation for the maintenance of good health. It is especially difficult to achieve the effective cooperation that is so clearly called for by the challenge of chronic illness. The physician, the professional nurse, the public health engineer, the medical social worker, the veterinarian, the chemist, the bacteriologist, and the statistician are all needed in this task. More important, the businessman, the legislator, the housewife, the teacher, and the newspaperman—the whole community—must lend a hand to the health worker.

The control of chronic illness and disability thus presents a dual challenge. The arduous quest for cause and cure offers a greater intellectual challenge than any hitherto known to the sciences of public health. And interdicting the causes and introducing the cures into everyday lives brings public health its ultimate challenge and responsibility—that of imbuing every individual with the knowledge and wisdom he needs to make his allotted years healthful, satisfying, and productive.

Preventive Action

PHR In the joint statement, Planning for the Chronically Ill, issued in 1947 by the American Hospital Association, American Medical Association, American Public Health Association, and the American Public Welfare Association, this statement appears:

"The basic approach to chronic disease must be preventive. Otherwise the problems created by chronic diseases will grow larger with time, and the hope of any substantial decline in their

By Lester Breslou, M.D., chief, bureau of chronic diseases, California State Department of Public Health.

incidence and severity will be postponed for many years."

The idea that a vast amount of chronic illness can now be prevented is still new although the Commission on Chronic Illness has done much to present means of prevention and to popularize the concept. Prevention means that—

- Thousands of premature babies in the future will not be blinded by too much oxygen during their struggle for survival.

- Because of insulin hundreds of thousands of diabetic persons are now in relatively good health although only a generation ago their lives would have been snuffed out or maimed.

- A simple, inexpensive test for detection and effective treatment makes it possible for thousands of women each year to be spared from having cancer of the cervix.

- Americans are more alert than ever before to the possible causes of lung cancer, which now accounts for 4 percent of all deaths among men.

- The Salk vaccine may prevent a high proportion of paralytic poliomyelitis.

- Serious rheumatic heart disease is preventable by prophylactic medication, as are many acute diseases which may produce chronic effects.

The Commission on Chronic Illness has listed more than 50 chronic diseases against which preventive action is possible.

Primary and Secondary Prevention

Prevention includes measures which avert the occurrence of disease and measures which halt or retard the progression of disease into disability or death. These two major goals of prevention are classed as primary and secondary prevention.

Primary prevention means keeping a disease from occurring. For example, we prevent silicosis of the lungs and chronic lead poisoning by industrial hygiene.

In the primary prevention of chronic illness, effective nutrition is a major immediate goal. Millions of older people in this country subsist

beds. Two patients are admitted to a mental hospital for every patient discharged. Nearly a third of those admitted to the best mental hospitals never return to the community. As much as one-third of the operating budget in some States is devoted to care of the mentally ill.

The National Mental Health Act of 1946 gave Federal support to the development of research, training, and community services. The Joint Commission on Mental Illness and Mental Health, under authority of the Mental Health Study Act of 1955, is making an objective analysis of the prospects in improved methods of care, treatment, and rehabilitation of mentally ill patients.

The expansion of the State-Federal program of vocational rehabilitation through the 1954 amendments to the Vocational Rehabilitation Act is a heartening development in the health field. Vocational rehabilitation is no panacea, nor is it relevant to the needs of many chronically ill patients. But the effect of the previously inadequate level of financial support for the program was to deny its benefits to about three-fourths of the people who could make good use of the service. The downward trend in the proportion of handicapped men and women returned to self-reliance and self-support has now been reversed.

Enactment of the Medical Facilities Survey and Construction Act of 1954 is providing financial assistance to the States for additional chronic disease facilities, outpatient diagnostic and treatment centers, nursing homes, and rehabilitation facilities.

Despite the efforts being made, progress in chronic disease control seems disappointingly slow when compared with the relatively rapid control achieved with certain acute communicable illnesses. Perhaps the halting pace of chronic disease and rehabilitation programs stems from the intrinsic nature of the problems. They are inherently different from the public health problems of the past, which were susceptible by their very nature to efforts by a few in behalf of the entire community.

Previously, the individual assumed little responsibility for public health services—for

water purification, pasteurization of milk, enforcement of pure food and drug standards, immunization procedures, and the like. This is not to assert that continued progress can no longer be made through environmental controls. Rather, in contrast to the era of environmental controls, we are moving into an era of public health in which individuals themselves must assume more responsibility for protecting their own health.

Community casefinding techniques can locate undiscovered diabetes, and practicing physicians and dietitians can prescribe for and instruct the patient. It is the diabetic patient himself, however, who must use the insulin and watch his diet and exercise. The cardiac patient alone is ultimately responsible for following his physician's instructions concerning digitalis, diuretics, and low-salt diets. The health of the patients is, to a considerable extent, in their own hands. The chronic diseases and disabilities are thus more a problem of the individual than of the community. They cannot be controlled without the understanding, motivation, and cooperation of the individual citizen. This will require new approaches in health education.

Few members of the general public are consciously aware of this fundamental shift in the nature of the hazards to their health. Many, however, do understand the economic consequences of this relatively recent change in health and medical care.

Chronic disease can be catastrophic to family finances. The costs of hospitalization, physicians' services, nursing care, and drugs can be overwhelming. A great need, therefore, is for better insurance protection against the financial risks of long-term illness and other expensive diseases.

To be sure, more than 100 million Americans now have some form of voluntary health insurance protection, but there are important gaps in coverage. Too few retired persons are protected. Only 4½ million people have major medical expense insurance although this form of protection is growing rapidly. Clearly, a great deal remains to be done to strengthen

conomic security can be greater than that of long-term illness. Nothing eats away retirement income and lifetime savings more effectively than does a long, expensive sickness.

Social Security Program

Let us take a look at the present public income maintenance programs and assess future trends in relation to the problem of chronic illness.

Most people who reach old age today are assured of at least a minimum income through the program of old-age and survivors insurance. During 1956 more than \$5½ billion will be paid out in benefits. Beneficiaries now number 8 million persons, including 6½ million aged.

We can confidently predict that more and more of the aged reaching retirement, or forced out of employment because of age or illness, will be assured of some income through old-age and survivors insurance. Others will have basic financial security through our public assistance programs. Planning in the field of chronic illness can, therefore, safely be predicated on the aged and chronically ill having at least minimum income. But assurance of a basic income is only one line of attack. What are we doing about their other problems?

The public assistance rolls include many persons with serious health problems. Of the 2½ million recipients of old-age assistance in the United States, some half million are bedridden or have some impairment which requires substantial care.

Almost 250,000 persons receive public assistance for the permanently and totally disabled. More than 100,000 receive aid to the blind. In addition, some 450,000 persons receive aid to dependent children because of the physical or mental incapacity of a parent.

Thus, nearly 1½ million people receive State-Federal assistance because of need attributable primarily to disability, chronic illness, or the severe infirmities of old age. Furthermore, a high proportion of the 2 million recipients of old-age assistance who are able to care for their own daily needs have health and other problems relating to aging.

Although persons are eligible for old-age assistance at 65, the average age of the 2½ mil-

lion recipients is 75. The typical recipient has been described as a widow aged 75, living alone in her own quarters, able to care for herself. If long-term illness strikes, as is likely at her age, expensive institutional care or special home care arrangements are almost inevitable.

OASI Beneficiaries

The beneficiaries of old-age and survivors insurance (OASI) are representative of the health problems of the aged in their retired years. It seems worth while, therefore, to review some of the findings of our national survey of aged beneficiaries in 1951.

They spent an average of 2¼ days during 1951 in general hospitals. They were incapacitated in other institutions for a little more than 1 day. They spent another 121⅓ days confined to bed at home. The total is approximately 16 days of more or less complete incapacity. It excludes the days when, despite heart conditions, arthritis, or other degenerative ailments, the beneficiaries were up and around.

One in twenty-five reported bed confinement at home or in a hospital or institution for 14 weeks or longer during the year. Incapacity of this duration has a serious impact on the general well-being of the family unit even when no hospitalization expense is involved.

One in every 250 was incapacitated in an institution other than a general hospital for an average of almost three-fourths of the year. More than half spent a full year in such institutions. Most of this care was financed at public expense.

About two-thirds of the total number of days of institutional incapacity was in mental hospitals, tuberculosis sanatoriums, veterans hospitals, or county or city infirmaries—in institutions that depend on public financing even though some patients may be charged on an ability-to-pay basis. Even for the OASI beneficiaries in proprietary nursing homes, an element of public financing was often present in that a public assistance agency was underwriting the bill.

Although less than 1 in 4 had hospitalization insurance, the proportion was significantly higher for those recently retiring than for those

on diets which are inadequate in protein, vitamin C, and other essential nutrients. They suffer impaired health because of lack of education in dietary matters, poor dentition, or low income, which keeps them from purchasing certain important foods.

On the other hand, many people are overweight, with resultant excessive mortality from cardiovascular disease, diabetes, and other chronic diseases, thanks to a generous diet, ease, and lack of physical exertion.

Popularization of optimum diet and optimum weight would carry us a long way toward primary prevention of chronic illness.

Secondary prevention means halting the progression of a disease in its early stages. For example, we find early glaucoma, a condition of hardening of the eyeball, by a simple test, and prevent blindness through treatment.

Major advances in the secondary prevention of chronic illness have been the development of simple, inexpensive tests for early detection of many diseases and the assembling of a battery of tests for screening large groups of apparently well people.

The chest X-ray for tuberculosis and lung cancer, hemoglobin and blood sugar tests, cytology tests for cancer, especially cancer of the cervix, tonometry for glaucoma, height and weight determination, and vision examinations are practical tests for the early detection of chronic disease. Combining the tests into a multiphasic screening battery to test large groups of people appears to be the most feasible means for health departments to accomplish large-scale prevention of chronic disease.

Multiple screening is steadily gaining popular support because it uncovers many cases of previously unrecognized and important diseases. The technique provides an excellent opportunity for health education. It develops and strengthens the patient-physician relationship by referring individuals to their physicians for necessary care. It is inexpensive, as low as 12 tests for \$5.

Epidemiological Study

Research is another important aspect of the

prevention of chronic illness. Needed perhaps most of all is epidemiological study of chronic disease. For example, why does coronary heart disease cause about 25 percent of all deaths in the United States today—more than in any other country of the world—even when we take into account the age distribution of the population? Patient, epidemiological study will help unravel the answer.

We also need research to improve and expand the array of tests for multiple screening.

State and local health departments, working with the medical profession, voluntary health agencies, and many other community groups, are now gaining the experience necessary to carry through the next great achievements in preventive medicine—the prevention of chronic illness.

National Health Trends

 In little more than a decade, medical research has made a major contribution in adding 5 full years to life expectancy at birth. But this gift of added years is a gift of years heavily weighted by chronic illness. With the conquest of the diseases of early life, more people are surviving to the ages when cancer, heart diseases, or other chronic illnesses are most prevalent. That the chronic diseases still unconquered tend to be those associated with aging takes on even greater significance for the future whenever higher proportions of our population will be aged.

Economic security and the maintenance of income have a close relationship to the problems created by chronic illness. Many of the chronically ill cannot work at all. For others, income is reduced, or the period of productive employment is lowered. No threat to eco-

By Charles I. Schottland, Commissioner of Social Security, Department of Health, Education, and Welfare.

vented. The Mental Health Study Act of 1955 has made an important start in this direction.

Using another line of attack on chronic illness, the State-Federal programs of vocational rehabilitation are demonstrating that many individuals handicapped by chronic illness can be restored to productive work.

To take heart disease as an example, the Office of Vocational Rehabilitation has granted funds for research into the rehabilitation problems of persons with heart disease; has provided grants-in-aid and technical advice to State rehabilitation agencies which, in turn, offer counseling, physical restoration, and job placement services; and has encouraged the establishment of local work evaluation units for heart patients.

For the 2,500 heart disease sufferers restored to productive lives through the program in 1955, earnings after rehabilitation were 15 times as great as earnings at the time of applying for rehabilitation services.

Children, too, have a direct stake in the fight against chronic illness. With the assistance of Federal funds, the States have made great strides in extending and improving services for promoting the health of mothers and children. Through prenatal clinics and well-child clinics, and through the provision of health examinations, nursing services, and immunizations, the younger population is equipped with its greatest weapon against chronic illness—a healthy start in life.

The crippled children's program locates children in need of care and provides the means of restoration through diagnosis, medical and surgical treatment, and the alleviation of unfavorable social and psychological influences that increase the degree and duration of disability. Through grants provided for special projects of regional or national significance, the benefits of medical research and new techniques have been made available to children with congenital heart disease who live in rural areas where highly specialized care is lacking.

This view of the future would have had better perspective if we were able to focus against a background of reliable data on the extent of illness and disability.

Illness Absenteeism

PHR Five years ago the Research Council for Economic Security undertook a nationwide survey on prolonged illness-absenteeism among employed persons. The survey includes 6,200 cases of nonoccupational disability only. Analysis of the data and the summary report will be ready for publication later this year. In the meantime, by reviewing the results of a subsample, which represents the illness-absence experience of some 80,000 man-years during which approximately 3,000 absences of more than 4 consecutive weeks each were reported, I can indicate what some of the findings are likely to be.

Meeting the Costs

The average gross medical care cost incurred by the absentees was some \$360, but in about one-fourth of the absences medical care cost more than \$500. The largest share was spent for hospital services. A little more than one-third was spent for physicians' fees. Almost 60 percent of the fees were for surgical services.

The extensive development of employee benefit plans in recent years is reflected in the subsample. The employing establishments all had some kind of medical care plan. As a result, 88 percent of the absentees received some benefits to help pay these costs. The others, who either were not members of the group plan or were not hospitalized, used medical services not covered by the plans.

Major emphasis in all of the plans is on hospitalization and indemnity payments for surgical procedures. Very few provide benefits for nonsurgical medical services in the hospital. Even fewer provide benefits for medical care costs incurred outside the hospital.

The benefits received covered almost 77 per-

By Gerhard Hirschfeld, director, Research Council for Economic Security.

who had come on the OASI rolls in the early years of the program. This indicates growth of voluntary health insurance will help to overcome the problem of financing care of the chronically ill.

The beneficiaries covered by hospital insurance averaged more days in general hospitals than did those without protection against illness costs: 2.8 days in contrast to 2.1. This difference is significant in the light of the lower average number of days of incapacity of all kinds for beneficiaries with insurance: 12.7 days in contrast to 16.6 days. It indicates the effect of prepayment in removing the cost barrier to hospital care.

Outlook for Health

From other sources, we know that an increasing proportion of the population will be able to continue their insurance against hospital and medical costs after retirement. This is hopeful, but there is still a long way to go. While about two-thirds of the population under 65 now have some form of prepaid hospitalization insurance, fewer than 1 in 3 of the aged have this protection.

We see growing concern for the medical care problems of public assistance recipients. The characteristics of recipients are such that we can assume they will in greater degree continue to need long-term care outside their own home. The 1950 census indicates that between 1940 and 1950 the number of persons aged 65 and over who were living in institutions other than general hospitals rose twice as fast as did the total aged population.

The largest relative increase in institutional care took place in homes for the aged and in nursing homes. This factor will add to the cost of medical care as a component of public welfare costs. Efforts of licensing and standard-setting authority, to which the 1950 Social Security Act amendments gave a long-needed impetus, and efforts of nursing-home operators to raise standards can be successful only if better financial support and more adequate personnel are forthcoming.

Our medical research efforts have been tre-

mendously strengthened, and further expansions are proposed. We must also increase our speed and efficiency in applying these findings to the treatment of patients and to our public health preventive programs.

The 1954 amendments to the State-Federal hospital construction program opened up new opportunities for the construction of chronic disease hospitals, nursing homes, diagnostic and treatment centers, and rehabilitation facilities.

I do not need to emphasize the importance of making hospital beds available to the chronically ill in special hospital wings, in nursing homes, and in facilities geared to long-term care and costing the patient much less than care in short-term hospitals. But I do want to point out that it would be unfortunate if methods whereby people pay for long-term care were to lag seriously behind the expansion of suitable facilities.

One hundred one million people in this country now have some form of insurance against hospital costs. Only a fraction, however, have insurance that covers nursing-home care or that is flexible enough to extend the days insured when costs per day are reduced.

A long stride forward was the recognition that there are other and better ways of caring for the chronically ill than in a hospital bed. We are seeing impressive demonstrations of what can be achieved through home care programs designed to provide the most suitable care for the invalid, in many instances at lower cost. Our progress is dramatically demonstrated when older people who have spent long years in mental hospitals are returned to normal existence and happy adjustments in their own communities. Care at home costs much less than care in a specialized hospital, and a bed is released for a younger patient who can be returned to productivity.

It would be folly to think that we can solve mental health problems by a wholesale exodus from mental institutions. But there is evidence that, through improved methods of care and treatment, the average length of hospitalization for mental patients can be materially reduced and a great deal of mental illness can be pre-

years of age. Certainly in this age group, a well-organized program of regular examination, early diagnosis, education, and other means, could be effective in preventing short-term illness from developing into prolonged illness.

Industry is in the best position to introduce practical measures for such a program. Prolonged illness-absenteeism may cost a company with 100 employees as much as \$10,000 a year.

Chronic Disease Services

PHR As a member of the Subcommittee on Chronic Disease and Rehabilitation of the Committee on Administrative Practice, American Public Health Association, I shared the responsibility of developing a manual on the health department's role in chronic disease and rehabilitation services.

In order to prepare the manual, which is nearly complete, the subcommittee found it necessary to learn about the type and extent of services being performed in health departments. Generally, we have found that State and local departments are not acting as effectively in the field of chronic illness as current professional knowledge permits even though they offer a variety of services for the chronically ill.

State Health Departments

For reference the subcommittee used the Public Health Service publication, *Distribution of Health Services in the Structure of State Government*, edited by the late Dr. J. W. Mountin. In attempting to bring Dr. Mountin's work up to date the subcommittee con-

cluded that at the State level the widely disparate picture presented in 1950 continues in a similar manner today although more programs have been developed and more States appear to be giving attention to chronic disease services.

Today there is also a wider understanding of the fact that for a long time most State health departments have been providing services related to chronic disease. However, these services are being performed within the context of the more traditional activities.

For example, under the banner of maternal and child welfare, there are three major programs: (a) the reduction of maternal mortality, particularly in its program to control toxemia and hemorrhages of pregnancy; (b) the reduction of infant mortality with recent emphasis on the prevention of premature birth and the prevention of death from prematurity; and (c) the provisions for services to crippled children.

In other traditional areas we find rheumatic fever programs; some aspects of programs for the control of tuberculosis, syphilis, and encephalitis, and for the elimination of pellagra; increasing statistical studies in applying the epidemiological approach to the study of chronic illness; increasing attention to screening and early detection; new emphasis on health education services; and provision of certain laboratory services. In most States we find various degrees of participation in rehabilitation programs.

In summary, the subcommittee study shows a long list of types of services only a few of which, however, are carried out by, or through, more than a small number of State health departments. The broad programs of California, New Jersey, and New York are the exception. There is more service and more consistency of program in States where the State health department received the stimulation of Federal funds, both regular grants and special grants.

Local Health Departments

Information on local health department services is derived from a subcommittee survey conducted in June-October 1955 under a contractual agreement between the American

By G. D. Carlyle Thompson, M.D., executive officer and secretary, Montana State Board of Health.

cent of the hospital charges and about 57 percent of the surgeons' fees but met only 10.5 percent of all the remaining medical care costs. The total benefits received paid for about 54 percent of the gross medical care costs. Some 31 percent of the absentees had other insurance coverage from which they drew some benefits.

The average net medical care cost—after deducting all benefits from insurance sources—was \$157. The average net cost for absentees in the higher income groups was somewhat greater, but it was not materially less for those in the lower income groups. This meant that a higher share of their earnings went for the medical costs.

For absentees whose annual earnings totaled less than \$3,500, and the largest number were in this group, the average net medical care cost incurred during their absence was \$138. The average net medical care cost for the single absence of the average wage earner was 5.5 percent of his annual earnings. For the absentees earning between \$3,500 and \$5,000, it was 3.7 percent. For those earning more than \$5,000, it was 3.3 percent.

To the medical care costs must be added the loss of the wages that might have been earned. Ten weeks was the average duration of absence, and \$800 would represent the average gross wage loss.

Again, the extensive development of employee benefit plans is reflected in the fact that 86 percent of the establishments had either sickness compensation or sick leave plans. Many had both. Of course, no insurance plan seeks to provide benefits equaling the full wage loss. These plans, too, like the hospital and surgical programs, are focused on the short-term disabilities. As a result, though they succeed in reducing the wage loss that absentees might have incurred, they succeed only to the extent of paying 43.5 percent of the wages the employees might have earned. The average net wage loss was about \$450.

Adding this wage loss to the average net medical care cost, we find that the average prolonged illness-absence among a typical group of employed workers represents a total

cost plus wage loss for the single abs approximately 15 percent of the annual earnings.

Financial Sacrifice

A primary objective of the survey was some idea about the economic impact of prolonged illness. On his return to work employee in the sample was asked what special sacrifice he made to pay the cost of illness. Here is the picture.

- 43 percent drew on savings set aside for special purpose, such as a house, car, or household appliance.
- 16 percent borrowed money.
- 15 percent arranged to pay for the medical care on a payment plan.
- Someone in the immediate family of 4 percent of the absentees went to work to help meet the expenses of the illness.
- 2 percent sold property or other belongings.
- 2½ percent applied for assistance outside the family, from a private welfare agency, public agency, company loan fund, or the church, for example.

A number resorted to more than one of these methods of meeting the costs.

Key Role for Industry

We have only begun to provide coverage for long confinements in the hospital, for unusual ancillary charges, and for the services of physicians other than hospital surgeons. There is almost no coverage for institutional care other than in an acute or general hospital. The development of such coverage must, of course, await further progress in construction of adequate facilities. There are great gaps in the coverage of services and other medical costs outside institutions—to cover physicians' care in the office, in clinics, and at home; to pay for other professional services and facilities while the patient is home or for continuous care after his return to work. The latter type of coverage is of particular significance in chronic disabilities.

About half of the absentees were under 45

The situation probably will become worse before it gets better. The public requires a shock to awaken a sense of responsibility for action. The following suggestions and predictions are offered.

1. Chronic illness must be considered broadly. It includes disabilities resulting from advancing age, crippling injuries that can be helped by rehabilitation, and general long-term illness. The individual must learn to live with "what he has left."

2. General hospitals should be powerhouses, not storehouses, in the treatment of prolonged illness. A general hospital is not intended for perpetual care. In prolonged illnesses, the hospital serves best for intermittent periods of intensive service.

3. Home care is a desirable alternative, not a "poor relation" of hospital inpatient service. The problem of cost is important, but more important is the idea that a patient may be a hospital patient while receiving supervised care in his home.

4. Outpatient service for long-term illness will increase at hospitals. This is not incidental; it is fundamental. Services provided at a hospital conserve the time of attending physicians, who should be paid for their work to assure continuity in the personal relationship.

5. Long-term illness generally leads to economic dependency. It causes interruption of employment as well as expenses for medical care. Many persons will require public support to supplement insurance benefits and private resources.

6. Much can be accomplished through better use of existing facilities and personnel. Home care by visiting nurse societies may avoid the need for additional hospital beds. Medical services at homes for the aged can serve the health needs of many residents. Rehabilitation through physical medicine, training, and sheltered employment will restore many disabled persons to a condition of self-help or self-support. Recreational and personal services will reduce some of the illnesses attendant upon lonesomeness and boredom.

Meeting the Costs

To an increasing extent, over the years, the medical reasons for people being on public assistance have been in the ascendency. About 43 percent of the 425,000 public assistance recipients in the State of New York in December 1955 were indigent because of a chronic illness or disability. This number included about 100,000 receiving old-age assistance, 40,000 receiving aid to the disabled, 4,000 receiving assistance to the blind, plus about 20 percent of the family heads of the 200,000 aid-to-dependent-children families and of the 80,000 home relief units. Considering all family units as individual cases, we estimate that 73 percent of the 225,000 cases on the public assistance load are there because of long-term illness.

In 1951 the average monthly expenditure for medical care for each public assistance recipient was \$3.88 as compared with an average monthly grant for all other purposes of \$39.35. In 1954 it was \$7.94 compared with an average of \$41.62 for all other purposes. The figures for medical care include physicians' services, hospital and infirmary care, drugs, nursing and physical therapy services, and laboratory services. Private nursing-home care is excluded.

The cost of hospital care accounts for a large part of the doubling of medical costs over the past 4 years since most welfare districts pay for hospital services on a per diem basis of actual costs, and, as everybody knows, hospital costs have been rising continuously.

Drug costs have become a serious problem except in the local welfare districts with rigidly controlled programs. Drug costs now comprise from 5 to 25 percent of the total costs of medical care whereas rarely did they exceed

By I. Jay Brightman, M.D., assistant commissioner for welfare medical services, New York State Department of Health, on detail to the New York State Department of Social Welfare.

Public Health Association and the Public Health Service.

We questioned 271 local health departments, generally the larger ones and the ones more likely to be undertaking chronic disease services. Of the 187 replies, 60 percent considered chronic disease activities to be a major responsibility, even though less than 10 percent of the group had established a division or unit devoted specifically to chronic disease.

As one might expect, the departments which consider chronic disease a major responsibility have developed a wider variety of services, and they participate in more of the services provided by other agencies.

Few of the departments had a working knowledge of most of the other chronic disease services available in the community.

More than 60 percent had participated in some kind of community survey relating to chronic disease. About 50 percent have seen the findings put to work by the community.

Only about half of the departments maintain any kind of current morbidity data on chronic disease and disability.

In a large proportion of the reporting departments, public health nurses make use of health workers serving in a wide variety of special fields. These other workers are employed, for the most part, by agencies other than the local health department.

For example, almost 90 percent of the local health departments in the survey make use of social workers, but less than 20 percent employ such personnel directly. Almost 75 percent of the respondents use the services of nutritionists, but less than 25 percent employ a nutritionist on their own staff.

It may come as a surprise that almost 40 percent of the local health departments play a part in providing local chronic disease institutions with nutrition consultation. Obviously, some of these departments use the nutrition consultant of the State health department, either directly or through their public health nurses.

Most local departments provide for physicians or health department patients, directly or indirectly, such laboratory services as cytologi-

cal studies for cancer cells or blood sugar determinations.

However, between 60 percent and 70 percent do urine analyses for both sugar and albumin and read chest X-ray films for tuberculosis, cancer, and heart disease.

A large proportion of local departments evidence an interest in providing consultative services to local welfare agencies. Other studies by the American Public Health Association, by its Subcommittee on Medical Care, raise some questions about the extent to which such services are actually used, however.

Most of the personal health services directly administered by the local health departments in the chronic disease field are in traditional areas of public health practice, but almost half of the departments offer some kind of screening program for more than one disease entity. And a large majority claim to offer an active referral service for patients needing care not directly provided by the health department.

A small number of the departments have experimented with nutrition classes, group sessions for obese persons, and followup of diabetic patients to make sure that medical supervision is maintained. Many departments offer a regular followup service of this nature for patients with rheumatic fever or for patients recovering from acute poliomyelitis.

Suggestions and Predictions

 Chronic illness is a daily disaster. More people are living long enough to suffer from prolonged illness and disability.

The problem is acute and requires community action, but many folks consider it a technical matter, to be solved by experts in medicine, public health, and hospital administration.

By C. Rufus Rorem, Ph.D., C.P.A., executive director, Hospital Council of Philadelphia.

The situation probably will become worse before it gets better. The public requires a shock to awaken a sense of responsibility for action. The following suggestions and predictions are offered.

1. Chronic illness must be considered broadly. It includes disabilities resulting from advancing age, crippling injuries that can be helped by rehabilitation, and general long-term illness. The individual must learn to live with "what he has left."

2. General hospitals should be powerhouses, not storehouses, in the treatment of prolonged illness. A general hospital is not intended for perpetual care. In prolonged illnesses, the hospital serves best for intermittent periods of intensive service.

3. Home care is a desirable alternative, not a "poor relation" of hospital inpatient service. The problem of cost is important, but more important is the idea that a patient may be a hospital patient while receiving supervised care in his home.

4. Outpatient service for long-term illness will increase at hospitals. This is not incidental; it is fundamental. Services provided at a hospital conserve the time of attending physicians, who should be paid for their work to assure continuity in the personal relationship.

5. Long-term illness generally leads to economic dependency. It causes interruption of employment as well as expenses for medical care. Many persons will require public support to supplement insurance benefits and private resources.

6. Much can be accomplished through better use of existing facilities and personnel. Home care by visiting nurse societies may avoid the need for additional hospital beds. Medical services at homes for the aged can serve the health needs of many residents. Rehabilitation through physical medicine, training, and sheltered employment will restore many disabled persons to a condition of self-help or self-support. Recreational and personal services will reduce some of the illnesses attendant upon lonesomeness and boredom.

Meeting the Costs

To an increasing extent, over the years, the medical reasons for people being on public assistance have been in the ascendency. About 43 percent of the 425,000 public assistance recipients in the State of New York in December 1955 were indigent because of a chronic illness or disability. This number included about 100,000 receiving old-age assistance, 40,000 receiving aid to the disabled, 4,000 receiving assistance to the blind, plus about 20 percent of the family heads of the 200,000 aid-to-dependent-children families and of the 80,000 home relief units. Considering all family units as individual cases, we estimate that 73 percent of the 225,000 cases on the public assistance load are there because of long-term illness.

In 1951 the average monthly expenditure for medical care for each public assistance recipient was \$3.88 as compared with an average monthly grant for all other purposes of \$39.35. In 1954 it was \$7.94 compared with an average of \$41.62 for all other purposes. The figures for medical care include physicians' services, hospital and infirmary care, drugs, nursing and physical therapy services, and laboratory services. Private nursing-home care is excluded.

The cost of hospital care accounts for a large part of the doubling of medical costs over the past 4 years since most welfare districts pay for hospital services on a per diem basis of actual costs, and, as everybody knows, hospital costs have been rising continuously.

Drug costs have become a serious problem except in the local welfare districts with rigidly controlled programs. Drug costs now comprise from 5 to 25 percent of the total costs of medical care whereas rarely did they exceed

By I. Jay Brightman, M.D., assistant commissioner for welfare medical services, New York State Department of Health, on detail to the New York State Department of Social Welfare.

10 percent in 1951. The increase is largely attributable to the remarkable advances in drug developments over the past decade.

Recognizing that the increased drug costs are largely due to the recent development of "wonder" drugs, drug audits in New York State still have indicated many areas where drug costs could be reduced by amounts varying from 10 to 15 percent. Such reductions lie in the area of greater reliability upon older drugs that are still tried and true, over which new proprietary medications have no established superiority. There is also the area in which more drugs are prescribed than the patient can possibly use without having toxic effects or without giving the drugs away or throwing them out. One gains the impression that the prescribing of drugs, the costs of which are rapidly approximating the costs of physicians' care, is a most inefficient operation.

Physicians' fees have not accounted for any major increase in total costs over the past 4 years although a 20-percent increase was allowed in 1954.

It is doubtful that much reduction in costs can be made in the hospital field except for greater awareness regarding the discharge of chronically ill patients to less costly places which can provide adequate care, mainly, to nursing homes and infirmaries, and to home care programs. We have noticed slight evidence of excessive physicians' calls. We do believe that physician cooperation could reduce drug costs to a small extent.

Many local welfare commissioners believe that welfare costs for the chronically ill are excessive, and they are alarmed at the continuous rise in these costs. Nevertheless, the majority recognize that the problems of welfare care are increasingly related to the problems of chronic illness and aging and that medical costs may be expected to increase both because of the greater number of such persons receiving welfare assistance and because of the continuously increasing costs of care.

Our survey of nursing and convalescent homes in upstate New York, undertaken in cooperation with the Commission on Chronic Ill-

ness, indicated that the majority of the homes provided adequate medical and nursing service. Few of the homes, however, provided medical or social rehabilitation, recreational services, or planning for any disposition other than continued stay at the home. Yet, a high percentage of the patients were out of bed except to eat or to rest, were able to walk alone or with the assistance of a cane or a crutch, were mentally clear, and were completely continent. It appeared that there should be immediate steps taken to provide more dynamic social and recreational programs for the long-term and mentally clear patients, and that there should be more intensive social and rehabilitation planning by physicians and social workers concerned with the individual patients. These additional services would naturally increase the costs for care in nursing homes.

The New York State Department of Health and the State Department of Social Welfare have developed a joint demonstration program for the rehabilitation of disabled public assistance recipients at the State rehabilitation hospital at West Haverstraw. The objective is to demonstrate what can be done for these patients and, if the results are favorable, to encourage local welfare departments to provide the full cost of such service.

A Call for Action

The summarizing committee agreed that we would like to consider the National Health Forum from the viewpoint, at least in part, of a member of the "consuming" public—one who must approve or support the types of action that have been discussed in the past 2 days.

By Morton L. Levin, M.D., assistant commissioner for medical services, New York State Department of Health, and chairman of the summarizing committee of the National Health Forum.

We were impressed by the fact that this has been truly a national forum on health. We have received greetings from the President, from 31 State governors, in person from Mayor Robert F. Wagner, and from Mrs. Franklin D. Roosevelt. We have been given the assignment of trying to set up guidelines for the Nation for needed action on chronic illness. In considering what action is needed, we have heard from 17 national, 7 State, and 19 local organizations, from State health commissioners, representatives of hospitals, a school of public health, and various types of voluntary and governmental agencies in local communities.

The Type of Action

What really was the subject of the forum? What have we been talking about? The summarizing committee agreed that these questions needed some clarification.

We have heard chronic illness described as "a daily disaster which is an acute emergency," and as "a major health problem which accounts for more than 70 percent of sickness." At the same time, we have heard chronic illness characterized as something in which hospitals, physicians, and the public generally are not greatly interested and for which it is hard to get money.

There seems to be some inconsistency in these two references to the term chronic illness. It hardly seems possible that there is a widespread lack of interest in the major causes of illness and disability. Perhaps what many people think of as chronic illness is not what we have been talking about, or only part of what we have been talking about. Apparently, to many people chronic illness means only the terminal, hopeless stages of illness, whereas it has been well established that chronic disease, in the sense in which the forum has used the term, need not necessarily bar a person from seeking the highest responsibility in our land.

Both by implication and by definite statement, the panel discussions have revealed that we have been discussing the effects of a large group of diseases which are well known by their individual names, such as cancer, heart disease, arthritis, cerebral palsy, vascular dis-

ease. Though many people are familiar with these diseases, apparently they do not know them under the general name of "chronic illness."

Most of the forum discussion was focused on certain types of action, which are needed for many chronic diseases at the same time—action that is not usually planned for a single chronic disease because it is needed for many chronic diseases at some stage of their course. One might call this type of action the common denominator aspect of chronic illness, and apparently this was the subject of the forum.

The summarizing committee was impressed with the repeated evidence that few people understand or are concerned about these common denominator types of activities. One possible conclusion to be reached from the deliberations of the forum is that the first action needed is to explain to the people—and especially to those who, by reason of money, power, and prestige, control community action—exactly what is meant by chronic illness in the terms of reference to the forum. Perhaps the forum has demonstrated that more of this type of explanation is needed before the desirable action is likely to take place.

The forum discussed parts of the common denominator aspects of chronic illness under various headings. Two panels discussed how to provide better care for the chronically ill at home or in institutions. Another panel was devoted to a specific kind of care, that called rehabilitation. Two panels were devoted to action by certain agencies—one by State health departments and one on what various types of city or county agencies were doing in this field.

Some of the Conclusions

The committee agreed that the most significant contribution made by the various panels was in describing examples of successful community action. We have heard many accounts of what may truly be called "success stories"—in developing home care programs; in linking hospital care with nursing homes, old-age homes, rehabilitation facilities, and home care;

and in bringing rehabilitation to people in nursing homes.

The examples we heard indicate that some communities have developed the know-how needed to lessen the disabling consequences of chronic illness, to give sick people the best chance to get back on their feet (that, apparently, is what is meant by "rehabilitation"), or to live their remaining years with as much activity, comfort, and decency as are reasonably possible. But, for some reason, the knowledge gained from these successes is not being used in most places. As to "why not?" the forum did not provide any specific answer.

We do not know why these common denominator types of action, which are obviously desirable, important, and useful, are failing to take place in more areas; we also do not know to what extent they are not taking place. The descriptions of the studies made by the Commission on Chronic Illness in Baltimore, Md., and Hunterdon County, N. J., the rehabilitation study going on in Kansas City, Mo., and in nursing homes in Peoria, Ill., suggest that the gap between demand and supply may be greater than has been suspected. These studies should tell us what are—to use one of the clichés in the field—the unmet needs.

Implicit in this conclusion is the need for an inventory of the extent of illness and disability in the Nation. The findings of the forum support the desirability of conducting a national survey of morbidity as a first step toward determining the most important gaps in providing care for people with all types of illness and especially for people with chronic diseases and disabilities.

A second implication is that a part of the money now being spent by various groups for specific diseases could well be earmarked for support of the common denominator services which are of importance to many chronic diseases. The forum also brought out the suggestion that some of these funds should be expended on an appraisal of how effectively the

rest of the money is being utilized for the various special programs.

Largely missing from the various discussions was a description of "the source of motion" for the action described. We were told about what happened but not why. We did not learn how it happened that a particular person or agency took the initiative for action. Exploration of these hidden springs of community action should prove helpful to those interested in promoting action in their own communities.

The discussions, however, did reveal some suggestions concerning the type of person or agency who might take the initiative. A president of a county or city medical society, a health officer, a council of social agencies, a visiting nurse association, a welfare department, and a general hospital were cited as specific examples.

The forum agreed that, when health leaders decide to initiate action, they should, first of all, bring people together to decide what is most needed in their community, and then develop a plan for specific action that people will understand and can start with; in other words, they should not necessarily try to do everything that needs doing at the same time.

As to priorities among programs recommended, there were outstanding examples: for instance, by almost unanimous choice, a home care program. Other activities which have high community acceptance are a referral and counseling service and rehabilitation programs for special groups of disabled persons, such as those in nursing homes.

Finally, the forum brought out the point that, if the need is shown for more effective services for the chronically ill, a good community leader usually can find the necessary money to provide at least part of these services. Apparently, the leader for developing these services should be an "actioneer"—a word coined by the forum—meaning one who combines the ability of an auctioneer in selling programs and the ability of a buccaneer in overcoming obstacles and opposition.

SERVICE with DISTINCTION

a story of the
Public Health Service

Filmstrip: 35 mm. black and white, 12½ minutes, with music and narration on record. 1955.

Filmograph: 16 mm. black and white, 10 minutes, with sound track. 1955. Identical with filmstrip but for use in a motion picture projector. "Dis-solves" and fast pacing give illusion of motion.

Audience: Professionals in the fields of clinical medicine, medical and biological research, and preventive health services.

Available: On loan from: Chief, Recruitment Branch, Division of Personnel, Public Health Service, Washington 25, D. C.

SERVICE WITH DISTINCTION is a pictorial story of Public Health Service activities throughout the world. Physicians, nurses, sanitary engineers, dentists, veterinarians, and other categories of professional personnel are shown carrying out representative activities in the Service's many continental stations and its overseas programs. Although useful in orienting audiences to the work of the Service, the filmstrip and filmograph stress opportunities for careers for commissioned officers in the Public Health Service. Opportunities for temporary duty in national emergencies as a member of the Service's Commissioned Reserve are also described. Using the technique of "quick cuts," "Service With Distinction" takes the spectator on a tour of the Service's installations in this country, harks back to its origin in 1798, and then describes professional opportunities in the fields of clinical medicine, research, and preventive health services. Scenes shown are those of PHS officers carrying out their assigned duties.

National Institutes of Health, Bethesda, Md.

United States Quarantine Station, Miami, Fla.

The Story of the Service Is a Story of People

"Service with Distinction" stresses the role of Public Health Service professional personnel, rather than installations and institutions. The story, as it unfolds, is about people, such as Lumsden, Stiles, Rosenau, Francis, Armstrong, and Mahoney, who have made the Service a vital health force through the world. The film moves on to describe the work of the Public Health Service commissioned officers in the United States and on health missions in other parts of the world.

... they have served with distinction since 1798

Lumsden and others have left their mark

... more than 250 occupational specialties

... a long-established career organization

... medical care ...

... medical and biological research ...

... preventive health services

... a medical officer in Liberia

In national disaster, the Commissioned Reserve

For commissioned officers, a variety of professional experience

Variations on the Theme Mental Health in Nursing

By RUTH E. SIMONSON, R.N.

ON a Sunday morning in March 1955, I opened the *New York Times* to the article, "Nebraska Fights Mental Illness."

As I read the description of the many innovations to enhance the treatment potential of mental patients, and the discussion of the part the institute could take in solving the problem of mental illness, my thoughts turned to what the Nebraska Psychiatric Institute could mean to nursing.

I visualized the new institute as providing an opportunity not only to advance our knowledge about psychiatric nursing but also to apply the knowledge to general nursing.

At this, the dedication of the institute as a research center in the care of the mentally ill, it is appropriate to consider some of the opportunities for psychiatric nursing which are

specific to this setting. Psychiatric nursing is being redefined, and the imperative need for both independent study and collaborative research is recognized.

For example, the statement of Dr. Arthur P. Noyes (1), that the nurse should be a psychotherapist in her limited but definite field, indicates that the breadth as well as the limits of psychiatric nursing must be made increasingly clear. The nursing profession itself must assume the responsibility for identifying its area of function and for describing and justifying what is done.

Psychiatric nursing needs exploration and study as to how it can enrich the profession of nursing. I do not question that psychiatric nursing leadership will do the exploring and at the same time safeguard its responsibility. My concern is with the enrichment of general nursing.

Will the schools of nursing, the nursing services, and community nursing programs, in their day-to-day work with the ill, take advantage of the opportunity to study psychiatric content?

Will general nursing work collaboratively with psychiatric nursing in applying psychiatric content to the care of the general patient?

Nursing and Mental Health

At its annual conference with State mental health authorities in December 1954, the Asso-

Miss Simonson is mental health nurse consultant for Public Health Service Region II, New York City. Her speech on mental health in nursing, in its original form, was part of the observance of Mental Health Week, May 1-7, 1955, when the Nebraska Psychiatric Institute, Omaha, was dedicated. Miss Simonson is a member of the council of the newly established mental health section of the American Public Health Association and vice chairman of the Interdivisional Council on Mental Health and Psychiatric Nursing of the National League for Nursing.

ciation of State and Territorial Health Officers gave formal recognition to the importance of mental health in nursing. At that meeting the association recommended that the principles of psychology be incorporated into all nursing and, particularly, into the community aspects of nursing (2). The health officers also recommended that each State mental health authority employ one or more mental health nurses to help carry out this recommendation.

The nursing profession shares the abundant interest in mental health evident in other professional groups. By its very nature, nursing is a personal and individual service which fosters close relationships. The nurse herself inevitably affects the mental health of the patients and families with whom she works.

The setting in which nursing is practiced offers its own unique opportunity for the promotion of mental health. The setting may be a hospital, a home, a clinic, a school, or a factory. The responsibility may be to the sick, to the convalescent, to the healthy. Yes, the nurse has opportunities in every phase of the mental health program. She shares in the prevention of mental illness, in the treatment of the mentally disturbed, in the rehabilitation of the mental patient.

Mental health in nursing lends itself to many variations. We accept that nursing has the potential for working constructively in mental health. Let us think of ways to nurture this potential.

The Use of Self

In nursing, we have tended to look at ourselves as outside the patient's problem. But little by little we have begun to tear down the wall that we built around ourselves. We are beginning consciously to take into account what the nurse, in her use of self, brings to a situation that changes it. The fact that there has been a shift in nursing research from functional studies in nursing service to a concern with nursing care which emphasizes nurse-patient interaction is proof of this change.

The report on "Favoritism in Personnel" in the February 1955 issue of *Nursing Research*, published the not-surprising conclusion that nurses like certain patients better than others

and that this factor makes a difference in the nursing care she gives. Her approach to the preferred patient is warm and friendly. He is respected as a person. The approach to the nonpreferred patient is more routine and business-like. He is treated as a patient (3). Recognition of this hitherto vaguely sensed bias is but the first step in its correction. The next step must be the development of appropriate methods to help the nurse meet the basic need of every patient to be treated as a person whether he is preferred or nonpreferred.

We have been content too long to emphasize the importance of recognizing the emotional components of nursing care. We have paid too little attention to the development of the skill that helps us apply the knowledge we have accumulated. Unfortunately, knowledge cannot be transferred directly and automatically to appropriate situations, for learning does not develop in that way. It is fostered in a climate where new approaches to traditional tasks can be tried out and modified.

Dr. George E. Gardner, writing in *Mental Hygiene* about higher education and mental health, makes the point that the development of emotional maturity is the first mental health task of the student. In that sometimes elusive search, he says, it is of primary importance to establish a realistic concept of one's self—one's ability and one's potentiality—and to establish a realistic appraisal of the responses to be expected from others (4).

Self-awareness, insight, and the realistic appraisal of responses come to the nurse as she works directly with her patients. That step in the learning process is hastened with competent guidance.

In a study completed in 1954 for the Public Health Service, Frances Kreuter and Marguerite Kakosh have developed criteria for qualitative appraisal of nursing care. I have been in fairly close touch with the part of their study concerned with communication as nursing skill. The graduate nurse students who participated were studying at the university and having field experience in a generalized hospital as part of it. They kept detailed diaries of daily patient care experiences. This included verbatim accounts of some of the conversations with patients for

whom they cared. With conscious attention they studied what the patient said and their own replies.

From subsequent discussions of the recorded conversations, it became apparent that nurses need to learn the skill of listening and to listen as nurses. Although the discussions showed intellectual acceptance of the value of encouraging expression of feeling, the students found it difficult as nurses to permit, let alone encourage, expressions of hostility or of any negative feeling when they were face to face with a patient. In fact, they shied away from any feeling which evoked uncomfortable feelings within themselves. This was not lack of concern for the patient but rather inability to allow any discussion that would interfere with the harmonious atmosphere nurses have been taught to consider essential.

One nurse, in reporting her experience with a patient, saw the problem in nursing care as one of uncooperativeness in following the physician's orders. Her real difficulty was in her effort to understand the basis for what seemed like deliberate perverse behavior. It was even more difficult for her to analyze her own feelings.

When she was asked, "Do you feel drawn to this patient?" she said "No," and, "Were you with him in your feeling?" she also replied "No." Then, when asked "Did you feel that you were against him in your feeling?" she replied, "Yes, but this is the first time I have ever looked at it this way. This is hard to face."

The process of looking objectively at one's self in a situation and gaining some understanding is indeed slow and sometimes painful. To do so requires supportive help. Perhaps this process can be illustrated best by two real situations.

Case Illustrations

Mr. Brown was referred to a public health nursing service after his dismissal from a rather prolonged hospitalization for a heart attack. His physician requested that he be encouraged and supported in increasing activity. Mr. Brown's condition and potentialities were reviewed with the nurse. She was familiar with the philosophy that the management of a car-

diac patient is directed toward improved physiology and that therapy combines judicious use of rest, activity, and modification of diet and daily living.

The nurse found Mr. Brown's family in a flurry of excitement at having him home again. His wife and his teen-age daughter, Marjory, hovered about trying to anticipate his every need.

He protested mildly, saying, "I've been doing a lot of things for myself at the hospital, Marjory. You make me feel like an invalid."

At this point, the nurse cautioned against "too much activity" and gave approval to Marjory's doing for her father the things he had been doing for himself. Throughout that first visit, as she carried out the appropriate techniques of nursing care, she admonished Mr. Brown to be careful. As she left, he remarked, "I thought coming home was a good idea, but I'm afraid that I came home too soon."

She was uneasy about the visit. She was aware of her reluctance to encourage increased activity for Mr. Brown although she accepted, intellectually, that it was important for his recovery. Through discussion she became more aware of what had happened during her visit. She realized that she had not supported Mr. Brown's movement toward health but had actually reactivated his feeling of helplessness and dependency. She recognized that she had reinforced the anxiety of the mother and daughter. She said, "I tried to reassure them, but they seemed more worried when I left."

On being encouraged to explore her own feelings about heart disease and talk about them, she recalled an experience as a student nurse.

She told of a cardiac patient on complete bed rest who openly defied the doctor's instructions and the nurse's admonitions by occasionally getting out of bed. One day he walked out into the hall to make a telephone call and died in the booth. "It was almost as if Mr. Morris were prompting me over my shoulder to keep Mr. Brown quiet."

This is an illustration of what I mean by saying that self-awareness and insight come as the nurse works directly with patients when she is helped to recognize how her own feelings influence the care she gives the patient.

Let's take another illustration. Bob, a 15-year-old, had been in the hospital with rheumatic fever for 2 weeks and on complete bed care for that time. He often looked unhappy, and the nurses tried to cheer him up by telling him how lucky he was that his heart condition had been discovered early and that he was under such good care. He was instructed in the necessity of "being careful when he went home" and "not to overdo."

On being dismissed from the hospital, Bob was referred to a public health nursing service. The doctor wanted him to have bed rest for a time, then graduated activity. The nurse's responsibility was to demonstrate and give nursing care and to help the mother carry out the doctor's orders. After several visits, the nurse came to the supervisor with this story:

"That kid just won't pay any attention to what he's told. He gets out of bed. He doesn't want me to give him his bath. He won't pay any attention to his mother; she's getting all worn out. The doctor told the father that he would be a cardiac cripple if the situation continued. His father is irritable with the mother and impatient with the boy. The boy won't pay any attention to his father either. And the young sister—she was such a nice kid—is turning into a regular pest. The whole household is at sixes and sevens."

This was a situation in which increased understanding of the adolescent was essential, first for the nurse, and then for the family: the need of the adolescent, for example, to be self-directing and to have some part in the planning that affects him, to be considered an individual in his own right. The need of the other members of the family and the implications of the illness were reviewed. The nurse was given help in ways in which she might involve Bob and his family in plans for his care. She was supported in her work with the family, and encouraged to express and analyze her own feelings about the way Bob behaved. Open discussion gave her a better appreciation of the emotional factors in the situation.

This example is given to show how certain mental health concepts become real as the nurse is helped to make practical application in her work with families. The unhappy and re-

bellious boy who was making his illness worse became very much interested in the therapeutic regimen as he was brought into the planning and in himself had a measure of control. The nurse felt that for the first time she had seen the implication of an illness for a family in relation to herself, with its possible implications for herself. She, too, had learned a measure of control by the conscious use of self.

In Touch With Others

With respect to freeing the potential of the nurse, it is important to emphasize the responsibility of administration for providing a setting in which quality nursing can be practiced.

Administration articulates and communicates the values in any institution or system. They may not be clearly articulated, but they will be communicated. If respect and concern for the patient is all important, that attitude will be communicated, and service, research, and training of personnel will reflect it. If, however, the development of specialized treatment is the only goal, and the patient is merely an accessory for research, that attitude, too, will be communicated. In that event, the system virtually prohibits nursing dedicated to the comprehensive care of the patient.

In addition to providing the environment for nursing care, administration has the responsibility of seeing that nursing is fully utilized in the service, research, and training activities of the institution. Though we are accustomed to think of research advances in other disciplines which may contribute to the preparation of nurses, how often do we think in terms of what nursing can contribute to other professions? The new climate in some of our teaching and research centers is making it possible to identify and describe some of the ways in which nursing can contribute to other disciplines so that they can be consciously used.

Dr. John Rose of the Philadelphia Child Guidance Center has written in an unpublished report:

"The nurse-family-child interaction is of primary importance in its own right. It is our experience, however, that the nurse is the only person who can fill certain gaps in the resident's experience." Dr. Rose was referring to his

own experience in the preparation of pediatric residents.

It is not enough to recognize that mental health is an integral part of all nursing or that the nurse should deal effectively with the emotional aspects that are a part of every situation she meets. Recognition, when we lack the knowledge and skill to function effectively, is immobilizing. The nurse must be helped in the use of self. That is her great potential.

Anne Morrow Lindbergh says it so simply for us in *Gift from the Sea* (5): "When one is a stranger to one's self, then one is estranged from others, too. If one is out of touch with one's self, then one cannot touch others."

It is our privilege to be in touch.

New Members of the PHR Board of Editors

Miss Arnstein

Mr. MacKenzie

Dr. Simmons

The 3 most recent appointees to the 13-member Board of Editors of *Public Health Reports* are introduced below. The new members, whose 3-year terms end in 1958, replace Dr. Justin M. Andrews, Dr. Ruth Freeman, and M. Allen Pond.

Margaret G. Arnstein, R.N., M.P.H., chief of the Division of Nursing Resources, Public Health Service, began her public health nursing career in Westchester County, N. Y. Subsequently, she served as consultant to the New York State Department of Health, first in the communicable disease field and later as district consultant for New York City. During the 3 years spent as director of the program for public health nurses at the University of Minnesota, she collaborated with Dr. Gaylord Anderson on the book "Communicable Disease Control." In charge of nursing for the UNRRA Balkan Mission, Miss Arnstein spent 15 months in the Middle East, where she organized nursing care in 2 Greek and 3 Yugoslav refugee camps and laid plans for work in the 3 Balkan countries under the mission.

Vernon G. MacKenzie is assistant chief for research and development, Division of Sanitary Engineering Services, Public Health Service.

After graduation from Massachusetts Institute of Technology in 1927, Mr. MacKenzie served 9 years in sanitary engineering research and design for the city governments of Chicago and Detroit. In the American Mission for Aid to Greece, he was deputy director of the Public Health Division. From 1948 to 1954 he was officer in charge of the Robert A. Taft Sanitary Engineering Center of the Public Health Service, Cincinnati.

Leo W. Simmons, Ph.D., is professor of sociology at Yale University, with a joint appointment in the department of psychiatry. He is also doing research under the auspices of the Russell Sage Foundation. Dr. Simmons was awarded his doctorate at Yale in 1931 and returned to the university in 1936 as a research assistant in sociology. Following field studies of the Hopi Indians in 1938 and 1941, he edited "Sun Chief," an autobiography of a Hopi Indian, 1942, and wrote "The Role of the Aged in Primitive Society," 1945. His study of the social aspects of medical care in hospital settings at Cornell Medical Center 1950-52 is reported in "Social Science in Medicine," with Harold G. Wolff as co-author.

Health Supervision of Infants and Preschool Children

THE Working Group on Service Programs of the Public Health Conference on Records and Statistics has evolved a series of suggestions pertaining to the collection, analysis, and interpretation of service statistics as tools in effective health supervision of infants and preschool children. It was necessary to limit attention to health supervision because of lack of time in which to consider such additional aspects of child health programs as pediatric clinics and care of premature infants.

The working group recognizes wide variations in program content and in stages of development and available facilities in health departments at all levels, and considers that changing concepts and new approaches are vital to the attainment of goals in public health work. Prescribing specific statistical patterns

which would be applicable to all health departments was considered neither desirable nor possible. Consequently, the proposals of the working group should be regarded as a framework within which each health department may develop a statistical program in accordance with its own desires.

Prerequisites to accumulation of meaningful statistics

The following conditions must exist if meaningful service statistics are to be developed:

1. The objectives and scope of the program must be clearly defined.

2. Statisticians and program personnel such as physicians, nurses, nutritionists, social workers, and health educators should have a part in determining the kinds of information needed and in developing plans for its collection. The statistician should function as a member of the professional team in initial planning of the program as well as in program operation and evaluation.

3. The purposes to be served by statistical data should be clearly specified. Reports should be prepared only to fulfill specific purposes.

4. Provision should be made in advance, during the initial planning stage, for periodic evaluation of statistical procedures.

5. Statistics developed for health supervision of infants and preschool children should be correlated with statistics developed for related programs of the health department. One

This is the second in a series of statements developed by the Working Group on Service Programs, originally named the Working Group on Service Statistics, of the Public Health Conference on Records and Statistics. In arriving at the conclusions embodied herein, the working group had the benefit of consultation with Dr. Martha Clifford, director of the bureau of maternal and child hygiene, Connecticut State Department of Health. The first statement was an outline of basic principles governing service statistics in public health, which appeared in the June 1956 issue of Public Health Reports, p. 520.

means toward this end is to have a records committee periodically pass on and review basic statistical forms of the several programs.

Kinds of information necessary for effective operation of service

Information desirable for operation of effective health supervision of infants and preschool children is of three main types:

1. Baseline data should be used for determining overall needs and for evaluating completeness of service. According to the definition developed by the working group, these baseline data are not included as service statistics. It should be emphasized that service statistics are most valuable when related to baseline data. The working group considered it appropriate to cite a few examples of baseline data useful for the planning and evaluation of infant and preschool health services: live births, by geographic area; infant and preschool deaths, by cause; illnesses reported, by cause; births occurring at home; economic status of population, by geographic area; racial characteristics of population, by geographic area; availability of private and voluntary medical and allied personnel, facilities, and services; and resources of the health department.

2. The second type of information is that which would assist physicians, nurses, and other health department persons primarily in giving service to individual infants and preschool children. The kinds of information listed below outline valuable statistics for operating an effective health program:

- Total number of individual children served by the health department (unduplicated count) distributed by geographic area, new cases and old cases, and characteristics of children served (age, sex, color).

- Volume of service (number of visits).

- Type of service, for example, physical examination, dental services, immunization, parent counseling, referrals to other medical services, and results of referrals.

- Site of service, for example, child health conference, home visits, and immunization center.

In order to obtain this information, the following types of data should be routinely available regarding each child served by the health

department: date of birth, sex, and race of child; geographic area in which child resides; date of admission to service; number of time served by the health department, in the home and in child health conferences; kinds of services received from the health department.

Individual health departments should develop applications of the statistics outlined above in combination with each other to meet the needs of their own programs. Examples are number of children immunized, by age; types of service given to new as compared with old cases; and volume of service by site of service. Such data may be compiled either routinely or through special studies.

3. Then, there are the kinds of information that would assist program administrators primarily in analyzing the operation of their programs. Types of data regarding operation of the program, which should be available either routinely or through special studies are these:

- Total attendance, by age group and status (new or old patient) of children, at each clinic or conference, and personnel time involved. For example, reports of clinic attendance might suggest changes in clinic policy, dates, hours, or location in order to adjust services to needs. Also, effectiveness of home nursing visits might be evaluated. Total clinic visits related to physician time can be used to evaluate clinic policies.

- Incomplete services indicated by number of children previously under care but not given service over a certain length of time; percentage of children with broken appointments; number of cases with undue waiting time between appointments; number of children who have not been vaccinated or immunized; and failures to respond to recommendations. This information may be used for evaluation of general performance and policy.

- Summary of program activity, for evaluating personnel needs of a program, and for justifying specific types of expenditures.

- Clinics in operation in relation to economic status of geographic areas.

Techniques for collection, tabulation, analysis, and interpretation of information

Source documents. Information for service statistics may be obtained from conference or

clinic attendance records, basic family unit records, individual case records, tickler cards, nurses' daily activity reports, and the like.

Methods of tabulation. Service statistics may be tabulated by:

1. Manual methods—These methods of abstracting information by manual sorting and counting up individual case summary cards, or tally sheets, are applicable in small health departments.

2. Marginal-punched, hand-sort cards—This method permits ready analysis where the volume of service is not large enough to justify mechanical tabulation.

3. Mechanical tabulation—This method is practical in health departments with a large volume of services.

Frequency of compilation. The frequency with which specific reports should be compiled must be determined locally depending on uses to be made of the data. Unduplicated counts of individuals served should be tabulated annually on a calendar-year basis and more often if needed.

Compilation of all service statistics on a calendar-year basis is recommended for comparison with baseline data. Where these statistics are required for fiscal purposes, compilation on a fiscal-year basis should supplement, but not substitute for, calendar-year data. The working group cautions against more frequent tabulations than are justified by use.

Special studies. Special studies are useful tools in program evaluation. They are recommended as a device to reduce the number and complexity of routine reports wherever possible. Routine reports should concentrate on minimum essentials for reflecting program, avoiding over-refinement of data.

Some types of service statistics which might be obtained through special studies are determination of levels of immunizations, evaluation of specific new services or program techniques (for instance, triple antigen, administration of vitamins), changes in behavior resulting from health department activity, determining reasons for lapses in attendance at child health conferences or for failures to complete immunizations, comparison of effectiveness of individual interviews and group conferences, and time and cost studies.

Methods of interpretation and presentation. The mere tabulation of data does not in itself provide for maximum utilization of service statistics. There should be a team approach in planning summary tables, narrative analyses, graphic presentation, trend data, and how and when the collected data are to be used.

Statistical measurements of service should be interpreted in relation to baseline data, needs for services, and program objectives. Only thus can an approach be made to evaluating accomplishments of programs.

The statement has been reproduced in mimeographed form as attachment A to document 229 by the National Office of Vital Statistics, Public Health Service, Department of Health, Education, and Welfare, Washington 25, D. C.

Under the title, "A Guide for the Collection, Analysis, and Interpretation of Service Statistics in Health Supervision of Infants and Pre-school Children," it has the endorsement of the following organizations: Association of State and Territorial Directors of Local Health Services; Council of State Directors of Public Health Nursing; and the Statistics Section, and Committee on Administrative Practice, American Public Health Association.

Comparative biochemical studies and counts of suspended algae and protozoa in a small Ohio stream give evidence that the effluent from a small sewage treatment plant characteristically causes an increase in certain green flagellates (Euglenophyceae) and the disappearance of the yellow brown flagellates (Chrysophyceae).

Stream Enrichment and Microbiota

By JAMES B. LACKEY, Ph.D.

IT has been well demonstrated that one ultimate effect of sewage or of treated sewage effluents is the fertilization of the receiving stream or body of water (1-7). This generalization, however, is seldom based on actual counts of species and of their numbers in the receiving waters. It is usually based on a study of a few kinds of organisms or of a broad classification, such as green flagellates. In the few instances in which the actual numbers and kinds of species occurring below points of waste or sewage admission have been studied (1, 4, 8, 9), no companion studies have been undertaken on nearby and somewhat similar waters as controls.

To provide more specific information on the fertilizing effects of a treated sewage effluent, an ecologic study of the suspended microbiota in Lytle Creek, a small stream in southwestern Ohio which receives such an effluent, was begun in the summer of 1944. In this study, the qualitative and quantitative distributions of the suspended algae and protozoa at points selected

to reflect the effects of the effluent were determined. For comparison with Lytle Creek, similar studies were made of Cowan Creek, an unfertilized stream in the same area, and of the Santa Fe River, a larger unfertilized stream in Florida. The findings of these studies are presented in the following pages.

Lytle Creek has been the scene of three earlier reports. Gaufin and Tarzwell (10) have described the known invertebrates (exclusive of protozoa); Cooke (11) has considered the ecology of the fungi; and Katz and Gaufin (12) have discussed the fish. These papers, together with the present one, give an account of the majority of the living organisms in Lytle Creek and provide what is perhaps the most nearly complete story of one stream.

The Ohio Streams

Lytle Creek is about 11 miles long. In the summer of 1944, when it was sampled for this study, it had a flow of about 1 cubic foot per second except after showers. The stream drained a small rural farming section and received the effluent from the sewage treatment plant for Wilmington, Ohio, a town of about 6,000 population (1940 census). The sewage effluent was the only pollution entering the stream. The stream showed a typical oxygen depletion just below the treatment plant outfall, with recovery before it entered Todd Fork about

Dr. Lackey is professor of sanitary science, College of Engineering, University of Florida. From 1945 to 1952, he was science editor for the Blakiston Co., and from 1935 to 1945, he was a senior biologist with the Public Health Service's Sanitary Engineering Center in Cincinnati, Ohio.

7 miles away. Typical dissolved oxygen ranges, pH values, and temperatures in Lytle Creek are given in the paper by Gaufin and Tarzwell (10) or the one by Cooke (11). Although the work reported in this paper antedates theirs, conditions were probably very similar.

Cowan Creek is located in an adjoining watershed and is similar in length and flow. However, its watershed, which is arable, pasture, or wooded land, is sparsely inhabited, and the stream receives no visible pollution. According to samples from one point, biochemical oxygen demand (BOD), the dissolved oxygen, and the nitrate content corresponded roughly to station V on Lytle Creek.

Sampling Procedures

Samples from Lytle Creek were taken at five stations, which had been set up for a study conducted by the Public Health Service. Their locations are shown in figure 1. Station I, at mile 8.7 above the mouth of the creek, was within the city limits of Wilmington. Station II, at mile 7.2, was a short distance below the outfall of the sewage treatment plant. Station III was at mile 5.2, where there was little visible evidence of the sewage effluent, and stations IV and V were at miles 3.2 and 1.0, respectively,

where the stream presented a practically normal appearance. Samples from Cowan Creek were taken at only one point, which corresponded in mileage from the mouth to Lytle Creek V.

These two streams were sampled approximately every 2 weeks beginning June 19 and ending August 15. The samples, totaling 33, were brought to the stream pollution investigation station at the Environmental Health Center (now the Robert A. Taft Sanitary Engineering Center), Public Health Service, and there analyzed for kinds and numbers of organisms and certain biochemical data. The sampling period covered the time of low flow and high temperature, when populations of algae and protozoa are normally at their highest. Practically every organism found had been recorded previously from other Ohio River Basin streams.

Results

The BOD values for Lytle and Cowan Creeks are shown in figure 2. The BOD figure of about 4 p.p.m. for Cowan Creek is close to the average for unpolluted creeks of this area that have been sampled. It is not surprising that the BOD value was so high at station II on Lytle Creek, since the dilution of the treatment plant effluent was not large. Perhaps the most sur-

Figure 1. Location of sampling stations in Lytle Creek.

Figure 2. Range in biochemical oxygen demand (BOD) in Lytle and Cowan Creeks, summer of 1944.

prising thing about the BOD values is the rapid decrease at the downstream stations.

The BOD values accord well with the values for nitrates and nitrites, shown in table 1. All three values, decreasing rapidly downstream, argue for large numbers of organisms, both saprophytic and holophytic (or saprozoic and holozoic), moving downstream.

A total of 167 species or genera of algae and protozoa were found in the 27 samples from Lytle Creek. In the 6 samples from the single Cowan Creek station, 92 species or genera were found. Table 2 lists all the species and gives the number of occurrences of each, by station.

Station I on Lytle Creek, the clean water station, had a total of 101 species, which occurred 195 times in the samples analyzed. These should have provided an excellent seedling for the downstream stations, if they were able to pass through the short zone of oxygen depletion, or possibly toxic zone, just below the treatment plant outfall. Forty-three of these species were found at station II. All of the Chrysophyceae and most of the Cryptophyceae, the Volvocales, and the diatoms (Bacillariaceae) were killed in the zone of pollution, but the remaining groups, which recovered only slightly

in species, recovered surprisingly in numbers of organisms.

The number of species found at station I in Lytle Creek was never again equaled. The only group showing a downstream increase in species was the green Euglenophyceae. Station V, the lowest on Lytle Creek, showed 20 fewer species than the comparable Cowan Creek station, which had 9 fewer species than the uppermost Lytle Creek station. Eleven of the twelve species of Chrysophyceae found in Cowan Creek were found not at all in Lytle Creek after station I: Evidently this group will not stand recent sewage pollution. Even some of the blue-green algae disappeared. Other groups adversely affected at stations II, III, and IV were the Cryptophyceae, the Dinoflagellata, the Volvocales, the Chlorophyceae (which die rather slowly in polluted water), and the diatoms.

However, the downstream decrease in number of species was compensated for by the increase in number of organisms. If 500 organisms of one species per milliliter is accepted as a bloom value (13), there were from 2 to 6 blooms at the downstream stations as compared with one bloom at station I and no blooms at the Cowan Creek station:

¹ Provisional name only.

The numbers of blooms at the downstream stations in comparison with the numbers at station I and in Cowan Creek are one evidence of enrichment. Further evidence is afforded by a comparison of the total number of organisms at each station. The numbers of organisms at sta-

tions II through V were much greater than the numbers at station I and in Cowan Creek, as shown in table 3. It should be noted, too, that only 5 samples were analyzed for each of the lower three stations, as compared with 6 for each of the others.

Actually, the fertilization of the downstream waters is apparent, on the basis of a marked increase in the number of organisms, for only a few groups. The blue-green algae were up sharply at station III, but they declined thereafter. The Cryptophyceae first dropped sharply, then rose to high numbers at station V. This pattern is a common occurrence for the Cryptophyceae. They apparently are favorably influenced by recent fertilization, but they seem to avoid high BOD values. The same is true of the small colorless flagellates, whose behavior in a stream seems to differ from their behavior in a sewage treatment plant. This difference, however, may be a sampling fault, since most of these organisms occur on or near the bottom.

Some of the data in table 3 are very difficult to explain. For example, the number of ciliates dropped steadily until station V, where there was suddenly a fourfold increase. This increase, however, was due almost entirely to *Balanitozoon agilis* and *Urotricha faretta*, two related ciliates whose food is largely unknown. These might have been feeding on some small bacteria that develop late in the cycle of organic degradation. Just how far we are from being able to foretell, or account for, the presence of a given organism in a stream is emphasized in a

recent paper by Wuhrmann (14). He showed an inability to produce a given biota in effluents similar as to BOD, oxygen consumed, nitrate content, and so on. He concluded that there were still unknown organic substances present that determine the nature of the biota.

The Euglenophyceae, however, clearly demonstrate the effects of stream enrichment. They were the largest group in number of species at each station, but they were low in number of organisms at the Cowan Creek station and Lytle Creek I. At Lytle Creek V they were more abundant than any other group, except for the single bloom of *Cryptomonas erosa* that occurred there. The Euglenophyceae showed substantial increases at stations II, III, IV, and V, and they were the most abundant group at station II. At station III, only diatoms and small green cells (*Chlorella*) outnumbered them; at station IV, only diatoms.

Use of the whole group of Euglenophyceae as indicators of pollution or of recent pollution has been questioned (14).

In the present study, the genera *Cryptoglena*, *Euglena*, *Lepocinclis*, and *Phacus* were found to be well represented in the enriched or recently polluted water; and many of the species not only tolerated the condition, they multiplied in it. Most of the species of these four genera that

were found occurred at or below station II in Lytle Creek, and most of the occurrences of these genera were in the polluted or recovery areas.

The genus *Trachelomonas* offers a different story. It was represented by only 6 of its many species, and only 1 of these 6, *urceolata*, increased markedly in the area of pollution, as shown in table 4. This is in decided contrast to the genus *Euglena*, which was represented by 18 species. Table 5 shows the behavior of the nine most common of these. All achieved substantial to large increases at stations II, III, and IV. All except *Euglena quartana*, which is a saprophyte, were present either in Cowan Creek or Lytle Creek I but in very small numbers.

Actually, then, the occurrence of many of the Euglenophyceae was favored by existing or recent sewage pollution, and there were a few species, such as *Euglena acus*, *E. agilis*, *E. pisciformis*, *E. polymorpha*, *E. gracilis*, and *E. quartana*, *Lepocinclis ovum*, and *Trachelomonas urceolata*, which showed heavy increases as a result of such pollution. These same species may bloom for other reasons, of course.

A few other organisms, such as *Oicomonas termo* and *Chlorella* spp., certain chlamydomonads, and naviculoid diatoms, behaved in the same manner. On the whole, however, it is easier to list the organisms that died as a result of the pollution. Here special emphasis would be on the Chrysophyceae or the Chlorophyceae. Perhaps analysis of a much larger number of samples would show some additional species to be favorably influenced by the pollution.

One species not identified in samples from other Ohio Valley streams was found in this study. This was *Cephalomonas granulosa*, one of the Volvocales, which is apparently rare. It occurred in Cowan Creek once, at Lytle Creek I three times, and at Lytle Creek V once. No significance can be attached to these occurrences, although there were 216 organisms per milliliter in Lytle Creek I in one sample.

Comparison With a Florida Stream

It may be argued that the numbers of organisms in Lytle Creek are not unusual and therefore do not support the idea that heavy growths follow enrichment. Cowan Creek, which was used as a control, was fairly similar to Lytle Creek chemically and biologically. For a comparison with a stream having different characteristics, the Santa Fe River in north central Florida was selected.

No data on BOD, nitrates, nitrites, or phosphorus for the Santa Fe River are available. However, it received virtually no sewage or industrial pollution and probably little agricultural drainage. The Santa Fe differs from Ohio Valley streams in that it is a brown-water (tannic and perhaps humic acid) stream with a pH tending toward acidity.

The Santa Fe River and two small lakes that contribute to the headwaters of the river were routinely sampled in 1953-54. A total of 81 samples from six points in the river and one point in each of the lakes were analyzed for kinds and numbers of organisms. In these 81 samples, 332 species or genera of algae and protozoa were found. Roughly, this is two

times as many species in three times as many samples as were found in Lytle Creek. The groups of organisms found in the Santa Fe system, by station, are shown in table 6. It is evident from this table and from table 2 that routine sampling of any body of water of fair size will reveal a large variety of algae and protozoa, unless there is some special restrictive reason such as extreme pollution.

At one river station, Mikeville, cattle used the small slough-like branch of the river proper, and this water was at times polluted. The pollution was evidently mild, however. Forty-three of the forty-seven observed species of Euglenophyceae occurred at this station, but

none of them ever attained bloom proportions.

There were only three blooms in the river during the time it was studied. All three were at Mikeville: one of a species of *Gymnodinium*, one of *Ankistrodesmus falcatus*, and one of the minute green *Chlorella*. Hampton Lake had three blooms, and Santa Fe Lake had eight. Of the latter, four were late summer blooms of blue-green algae, quite in keeping with lake behavior. The bloom organisms did not enter the river to any extent because the very small amount of water draining from the lakes passes through marshy, grass-grown channels.

The Santa Fe, then, is a largely unpolluted stream that is rich in kinds of algae and pro-

S=samples.

tozoa, but poor in numbers of organisms. It contained many organisms common to Lytle Creek, and the increase in kind and number of organisms at the Mikeville station indicates that it might well exhibit blooming if well fertilized. These observations strengthen the idea that plentiful enrichment of a stream causes a great increase in organisms, and also that the kind of bloom is a function of the type of enrichment. At Mikeville, where the water was muddied by cattle and polluted by their droppings, a sharp and heavy increase in Euglenophyceae occurred. This fact and the Lytle Creek study both indicate that some Euglenophyceae increase as a result of fecal pollution.

Bloom Potentials

A plentiful supply of the proper nutrients is certainly essential for blooming. That the nature of the nutrient material determines both the strength and nature of blooming has been indicated by a number of observations. In the laboratory at the University of Florida, for example, commercial fertilizer has been repeatedly added to concrete tanks that are filled with water from a small brook. The brook is spring-fed but it contains a varied plankton, including Euglenophyceae. These tanks develop heavy blooms—of small Chlorophyceae. A few *Euglena*, *Phacus*, and *Lepocinclis* organisms occur in the bloom, but their numbers are always small. As another example, never in any pond I have observed has the addition of commercial fertilizer produced a bloom of *Euglena sanguinea*; but when similar ponds are invaded by cattle this organism frequently blooms heavily.

In addition to the proper nutrients, the proper seed must be present. Few protozoa or algae, however rare they may be, seem likely to be absent in most environments. There are broad limits—acid water vs. hard; low salinity vs. high—for certain species or groups. *Gonyostomum semen* is practically never found in hard water, and *Gymnodinium brevis* has never been recorded from any part of the world other than the Gulf of Mexico off the Florida coast and Trinidad, B. W. I. (16). Instances such as these are rare, however, and probably would be greatly decreased by additional and much

more critical observation in many parts of the world. In almost every instance in which a single group of organisms has been studied extensively in a particular geographic area, investigators have found most of the known species of that group (within their broad ecologic limits). A recent example of this is the study by Decloitre (17) of the thecate rhizopods in French Equatorial Africa. He found most of the known species. He recognized climate as a barrier for some species, but also stated: "The intertropical zone is little known as a whole; it is very probable that a certain number of these species will be found, sooner or later, in this climatic zone and will be recognized as ubiquitous."

It is unwise to state that a micro-organism species—that is, the seed—is absent from a given environment. One reason is that the environment may not have been adequately sampled; another is that the sample may not have been completely analyzed. It is difficult to examine completely even a single drop of water in a sample. Many workers make one examination, then set the slide aside in a moist chamber to reexamine later. The question inevitably arises as to what size sample must be analyzed to yield a given species. Or otherwise stated, what is the chance of finding a given species in a random sample?

Fisher, Corbett, and Williams (18) consider that the majority of species are rare, only a few being common. Therefore, the species in a biological group would not be equally abundant, even though an environment might be sampled a number of times under uniform conditions. This is equivalent to stating that conditions in the habitat sampled were optimal or nearly so for the "common" species, but only within the range of tolerance for those that occurred less frequently. I do not recall ever having seen *Trachelomonas reticulata* but once, despite having examined thousands of samples of foul water, presumably its preferred habitat. This one occasion was a sample from a tree hole, and it contained a dense population of this species.

No answer has been evolved thus far as to approximating the maximum probability of finding a given species. It may reside in knowing the preferred habitat for the species, then sampling as near to it as possible. The range

of tolerance should be known, too. That some organisms exhibit a wide range is shown by the studies of Lytle Creek and the Santa Fe River. Lytle Creek is a hard-water stream, well fertilized, in a temperate zone. The Santa Fe is a larger, soft-water stream, with little fertilization and probably much tannic and humic acid, located in a subtropical environment. Yet these streams had 99 species in common. In addition, many of the species occurring in only one of these streams have been found in habitats near the other stream. More complete analyses, or perhaps more numerous ones, would probably reduce still further the species found in only one or the other area. The question, then, is what peculiar conditions give rise to an abundance of a given species.

Such considerations as these emphasize the importance to the ecologist of careful chemical and physical studies of a habitat. Perhaps we may yet be able to say with certainty that, since an environment presents certain characteristics, we can expect to find certain species there.

Summary and Conclusions

In comparative studies of three streams in the United States, quantitative and qualitative determinations of the suspended algae and protozoa provided specific evidence of the fertilizing effects of a treated sewage effluent on some species of these organisms.

In Lytle Creek, a small stream in southwestern Ohio which receives effluent from a primary sewage treatment plant, a total of 167 species were found. Certain species of Euglenophyceae were exceptionally abundant at points below the plant outfall. Chlorophyceae and Chrysophyceae were adversely affected by the effluent.

Of 92 species of microbiota in Cowan Creek, a similar but unfertilized stream in the same area, only Chrysophyceae and diatoms (Bacillarieae) were abundant.

In the Santa Fe River, a larger unfertilized stream in Florida, 332 species were found, but none of them occurred in large numbers.

Species common to both the Ohio and Florida waters totaled 99, indicating a wide environmental tolerance for these species.

The more intensively a given environment is

sampled, the greater is the possibility of finding a given species therein, provided the environment falls within its range of tolerance. The environmental ranges of many microorganisms are wide enough for the organisms to be termed ubiquitous. But such organisms may reproduce rapidly enough to form blooms only within a narrow range the critical factor, or combination of factors, of which rarely occurs. Recent fecal pollution appears to be one such factor for certain species of Euglenophyceae. The same environment appears to be limiting for some species of Chrysophyceae.

. . .

A list of the micro-organisms found in the Santa Fe River may be obtained from the author.

Air Pollution Research

Five Federal agencies have been awarded contracts for community air pollution research in the Public Health Service air pollution program, for use during fiscal year 1956.

The Weather Bureau, Department of Commerce, allocated \$196,000, is studying the dilution and dispersal of contaminants in the atmosphere. The assignment includes devising ways of surveying problem areas, evaluating existing weather data to determine air pollution potentialities, and predicting weather conditions that may intensify air pollution.

The National Bureau of Standards, Department of Commerce, has been allocated \$98,000 for developing methods of analyzing and identifying various gaseous contaminants of the atmosphere. This bureau is exploring ways of collecting and treating condensable pollutants and of analyzing concentrated samples of the atmosphere. It is also studying reactions among gases and other chemicals in the air.

The Bureau of Mines, Department of the Interior, also allocated \$98,000, is investigating causes of inadequate incineration of combustible wastes and means of improving incineration. It will study sulfur dioxide removal processes and evaluate elements from internal combustion in engines which may contribute to air pollution. It will also sample a limited selection of stack effluents.

Additional agreements with other Federal agencies include one with the Library of Congress for the preparation of a continuing annotated air pollution bibliography and one with the Department of Agriculture for the assignment of a plant physiologist to the program. The physiologist will initiate investigation of the use of plants as air pollution indicators and assist in coordinating the air pollution activities of the Service and the Department of Agriculture.

Contracts for research to be conducted by non-Federal agencies were consummated with the following: Baylor University for a preliminary study to determine the feasibility of using tissue enzymes to evaluate the toxicity of air pollutants (\$34,000); the University of Nebraska for a study to determine the feasibility of using tissue culture to evaluate the toxicity of air pollutants (\$31,000); the State College of Washington for the development of an automatic air pollution sampling and recording instrument (\$17,590); and the Franklin Institute for a study of the feasibility of collecting and storing air samples by compressing atmospheric air and storing it in suitable containers for subsequent chemical or physical analysis of vapor-phase contaminants (\$16,064). Other contracts for research are being negotiated.

Diagnosis of Psittacosis in Parakeets

By R. E. KISSLING, D.V.M., M. SCHAEFFER, M. D., O. K. FLETCHER, B.S., M.P.H., D. D. STAMM, V.M.D.,
M. A. BUCCA, Ph.D., and M. M. SIGEL, Ph.D.

THE RECENT remarkable increase in the popularity of parakeets (budgerigars) as household pets poses a question of whether this trend has been accompanied by a rise in the incidence of psittacosis. With increasing awareness of this disease, there has undoubtedly been a tendency to diagnose and report cases which in other times might not have been identified. Nevertheless, there appears to have been a real rise in the attack rate of psittacosis (1,2). This emphasizes the need for a rapid and simple diagnostic test for psittacosis that can be used by local laboratories.

The clinical resemblance of psittacosis to other forms of pneumonitis and influenza-like illnesses makes confirmation of the diagnosis by laboratory methods almost mandatory. Early antibiotic therapy, so often employed today, makes impossible the diagnosis of psittacosis by

isolation of the virus from suspected human cases. Such therapy may also suppress or delay antibody development, leaving the physician without any direct laboratory support for his clinical diagnosis. Quite often the pet parakeet or other psittacine contact may be the only supportive evidence for such diagnosis.

Psittacosis virus may cause an apparent or inapparent infection in birds, but even in the overt disease the symptoms are not pathognomonic. Moreover, apparently healthy birds frequently shed psittacosis virus. Physical examination of the bird is insufficient for a correct diagnosis in sick birds and entirely inadequate for the detection of silent infections. The isolation of the virus from infected birds offers the most accurate diagnostic method, but it entails sacrificing of the birds to obtain tissues, a procedure often objected to by an owner for sentimental reasons and by breeders or dealers for economic reasons. Therefore, a less expensive test was sought, one which would reliably detect infection in live birds.

Serologic tests, particularly complement fixation tests, have proved to be of diagnostic value with human serums (3). The complement fixation test has also been found to be useful in tests with pigeon and parrot serums (4, 5). The serums of domestic fowl, while not reacting in the usual complement fixation test, will yield definitive results when tested by the indirect complement fixation test (6, 7). The serums of sea birds infected with psittacosis virus also have been shown to react in the direct complement fixation test (8).

It appeared desirable, therefore, to compare

Drs. Kissling, Schaeffer, Stamm, and Bucca are with the Virus and Rickettsia Section, Laboratory Branch, Communicable Disease Center of the Public Health Service, Montgomery, Ala. Dr. Kissling is chief and Dr. Stamm is his assistant in charge of the Veterinary Research Unit. Dr. Schaeffer is chief of and Dr. Bucca is a bacteriologist with the section. Also, Dr. Schaeffer is an associate professor of bacteriology and immunology at the Emory University School of Medicine and a visiting lecturer at the Tulane University School of Medicine. Mr. Fletcher is a biologist with the Georgia State Health Department, Atlanta, and Dr. Sigel is associate professor of bacteriology at the University of Miami Medical School.

the results of the complement fixation test on serums of parakeets bled during life with results of virus isolation attempts from their droppings and from their tissues when they were subsequently sacrificed and to investigate the possibilities of practical application of serologic techniques for the detection of infected flocks.

Materials and Methods

The parakeets in this preliminary study were obtained from 19 different owners of small "backyard" aviaries in the vicinity of Albany, Ga., except for one flock which was selected from a larger group confiscated by the State of New Jersey.

Bleeding of Parakeets

Serum was obtained from the parakeets by bleeding from the jugular vein, using a 25-gauge, $\frac{1}{2}$ -inch hypodermic needle attached to a 1.0-ml. tuberculin syringe which was previously wetted with physiological saline solution. The parakeets were anesthetized with ether before bleeding. One ml. of blood was withdrawn and the serum separated from the clot by centrifugation. The birds withstood the removal of 1.0 ml. of blood quite well. In fact only one bird of this series died following the bleeding, and this death was apparently caused by excessive anesthesia.

Antigen

Two psittacosis antigens were used. The first antigen was prepared from allantoic fluids of chick embryos infected with psittacosis virus recently isolated from a parakeet. The embryos were inoculated intra-allantoically with 10^{-1} or 10^{-2} dilutions of virus on the eighth day of incubation and the fluids were harvested 5 to 6 days later. These were centrifuged at 1,000 r.p.m. for 10 minutes and heated at 100° C. for 20 minutes or treated with phenol in 0.5 percent concentration. The second antigen consisted of heated and phenolized yolk sac material from infected chick embryos.

Complement Fixation Test

The procedure for the complement fixation test was as follows:

Serial fourfold dilutions of heated inactivated serums were made in veronal buffered saline. The first dilution varied from 1:2 to 1:8, depending upon the quantity of serum available. The serum dilutions were distributed in 0.1-ml. volumes to 3 rows of tubes. The first row was the test row and received 0.1 ml. of psittacosis antigen in optimal dilution. The second row served as a control for nonspecific reactions and received 0.1 ml. of normal allantoic fluid in the same dilution. The third row measured anticomplementary activity of the serum; it was given 0.1 ml. of veronal buffered saline.

To each tube was added 0.2 ml. of complement diluted to contain 1.5 to 2 units. The tubes were placed in the refrigerator overnight. Following this, 0.2 ml. of sensitized sheep cells (consisting of equal volumes of 2 percent cells and optimally diluted hemolysin) were added and the tubes incubated at 37° C. for 30 minutes. The titers represent serum dilutions which gave 3+ or 4+ readings followed by readings of "zero." When a 4+ was followed by a 1+ or 2+ reading, the titer was interpolated as being midpoint between the two dilutions. For example, if 1:16 dilution gave a reading of 4+, and 1:64 read 2+, the titer was considered to be at 1:32.

Each test was accompanied by the usual positive, negative, hemolytic system and cell controls. Unpublished results obtained in this laboratory indicate that human serums can be tested successfully with either psittacosis or lymphogranuloma venereum (LGV) antigens, but parakeet serums tended to react more specifically with psittacosis antigen in the complement fixation test. The psittacosis antigen may be preferable, therefore, for the testing of bird serums.

The indirect complement fixation test was performed by incubating at 37° C. for 1 hour 0.1 ml. each of the test serum, complement (2 units), and antigen (2 units). After this 0.1 ml. of a psittacosis immune mammalian serum (2 units) was added and the mixture again incubated for 1 hour at 37° C. Finally 0.1 ml. of 4 percent sensitized sheep cells was added and readings were made after 45 minutes incubation at 37° C.

Each test was accompanied by a direct fixa-

tion control in which a negative mammalian serum was substituted for the mammalian psittacosis positive serum. The usual controls for nonspecific, anticomplementary, and hemolytic reactions were also included for each test serum. Any serum which inhibited the fixation of complement by the known positive serum as indicated by readings of "zero," 1+, or 2+ was considered positive even if this reaction was observed only in the most concentrated dilution.

Virus Isolation

For virus isolations from excreta, the droppings from individually caged birds were suspended in a solution of 10-percent horse serum in buffered water, the proportions being approximately 1:3 by volume. After centrifugation at 300 times gravity for 10 minutes, the supernate was removed. Streptomycin sulfate was added in concentrations of 2.0 mg. per ml. of supernate, and the mixture was inoculated in volumes of 0.3 ml. intraperitoneally into groups of 3 to 5 mice which were 3 to 4 weeks old. Psittacosis virus was considered isolated when the mice developed ascites or died, with typical elementary bodies being demonstrated in smears from the peritoneal serosa.

When testing for virus in the tissues, an approximate 20 percent suspension of the liver and spleen of each bird was prepared and inoculated intracerebrally in volumes of 0.03 ml. into groups of 5 mice. Demonstration of elementary bodies in the smears from the meninges following a typical course of symptoms and death was the criterion of virus isolation.

Results

The results observed from testing 130 parakeets for both the presence of specific direct complement-fixing antibody in their serum and for virus in their tissues are shown in table 1. There was agreement between the two tests in 85 of 125 birds (5 were unsatisfactory in the complement fixation test). Of 30 birds from which virus was isolated, the serum of 5 failed to give a reaction in the complement fixation test. It is possible that serums from these birds were taken early in the infection prior to the development of demonstrable antibodies. The serum of

a sixth bird was anticomplementary. No virus was isolated from 35 of the 59 birds whose serums gave a positive complement fixation reaction. This could mean that the virus isolation test was not sensitive enough to detect the amounts of virus present at the time, or that these birds had actually recovered from psittacosis infection and were free of virus but still possessed circulating antibody.

Birds from 13 flocks failed to yield virus when their livers and spleens were tested (table 2). Fifty-five of the fifty-eight birds so represented also failed to show complement-fixing antibody in their serums. Both tests yielded

positive results in 6 aviaries. The degree of correlation varied from 15 virus isolations versus 21 positive complement fixation tests (aviary 1) to 4 isolations versus 25 positive complement fixation tests (aviary 9). These findings may signify differences in the duration of infection in these 2 aviaries.

From flocks known to be infected, 74 parakeets were selected for a comparison of results of virus isolation from the droppings taken during life and from the liver and spleen at autopsy when sacrificed. Several samples of droppings were tested from some of these birds; only single samples were tested from others. Serum specimens were taken from all of the

birds for parallel serologic studies. The results are shown in table 3.

Of the 23 parakeets in which tissues yielded psittacosis virus, only 13 shed virus in their droppings. The age or sex of the bird did not appear related to the excretion of virus. Virus was isolated from the droppings of one young female parakeet although no virus was obtained from its liver and spleen upon autopsy. In most cases repeated samples of droppings were taken at weekly intervals. Only 2 of the 10 birds which gave evidence of virus in any of three fecal specimens were excreting detectable amounts in all three samples.

The five birds with serums that gave positive

 1 Or greater.

complement fixation reactions at dilutions of 1:128 or greater were all shedding virus in their droppings. However, several which shed virus had CF titers of only 1:8, and three birds yielding virus from both droppings and tissues had no demonstrable CF antibodies. Possibly, the latter two groups of birds were in early stages of infection. Further studies on the pathogenesis and immunology of the disease in birds are necessary for proper interpretation and correlation of these data.

Of one flock of 49 birds examined by the complement fixation test, the serums of 25 reacted with psittacosis antigen. Ten of the reactors were removed and isolated from the flock 12 days later, and attempts were made to isolate virus from their droppings. Virus was recovered from only 2 of the 10. The remaining 15 reactors were then isolated from the flock 49 days after the original testing, and again virus was isolated from the droppings of 2 of these birds.

Fifty-five days after the first bleeding, second serum specimens were collected from the 24 birds which previously had shown no antibody. By this time all but one bird gave positive CF reactions with psittacosis antigen. Between the time of the first and second bleeding, breeding activities were initiated in this flock. This circumstance, plus the delayed removal of infected birds, may have been responsible for the apparent spread of infection within this flock.

A large group of young parakeets obtained from a wholesale dealer in New Jersey became available for study. Fifty of these birds were killed and their tissues tested for the presence of virus. Five of these yielded psittacosis virus. However, no antibody could be demonstrated in 197 serums by repeated direct complement fixation tests in which all controls indicated a satisfactory test.

These serums were then examined by the indirect complement fixation test. The type of correlation to be expected within an infected flock became apparent with the results obtained by this indirect test. Of 87 parakeets tested by both serologic and virus isolation techniques, 26 were negative by both tests, 23 were positive by both tests, 35 were serologically positive but failed to yield virus, while 3 were serologically

negative yet virus was isolated from their tissues (table 1).

Summary and Conclusions

In the parakeets studied in this series, a close correlation was demonstrated between the results of complement fixation tests for psittacosis antibody and of virus isolation from tissues. Psittacosis virus was isolated from 47 of the 117 birds showing either direct or indirect complement fixation antibody titers of 1:2 or greater. Virus was not isolated from 87 of 95 parakeets whose serums contained no demonstrable antibodies. Most of the birds with antibody from which virus could not be isolated were obtained from known infected flocks. Conversely, only the serums of 3 of 55 birds obtained from flocks considered to be free of psittacosis virus (on the basis of a 10 percent sampling) reacted positively to the complement fixation test and then only in a low titer. A larger sample might have indicated that virus was present in the two flocks from which these birds came.

The significance of a positive titer in relation to the infectiousness of an individual bird remains to be determined, but the finding of at least some birds with antibodies may be regarded as evidence of past or present infection in that flock. Such a flock should be suspected and the birds with negative serums should be retested in 3 to 6 weeks. The presence of additional birds with antibodies at this time would provide presumptive evidence that active infections were present in the aviary. Continued absence of antibodies in a flock may be considered an indication of absence of current active infection.

The reason why some birds develop antibodies that can be detected in the direct complement fixation test while others develop only indirect complement-fixing antibodies is not understood. However, the results indicate that parakeet serums should be subjected to both tests before being considered negative.

Although isolation of virus will remain the most conclusive method for the diagnosis of psittacosis in individual birds, this expensive and time-consuming procedure need not be applied for the detection of infection in flocks.

Where facilities for virus isolation do not exist, or the number of birds to be tested is excessive, the complement fixation test should prove to be especially valuable. Aside from being one of the more reliable of the complement fixation tests for virus, it is relatively rapid and simple. This test should be added to the diagnostic armamentarium of every local public health laboratory.

Increase in Juvenile Delinquency

The Children's Bureau, Department of Health, Education, and Welfare, has been receiving an increasing number of requests for help from States and communities who are trying to plan services for delinquent children more effectively.

The Bureau reported on May 20 that about a half million children were brought to juvenile courts for delinquency in 1955 and that juvenile delinquency continued to increase during that year. The Bureau, which annually receives reports from a number of juvenile courts on the juvenile delinquency cases they handle, has prepared preliminary estimates of the rates of increase.

Some 977 courts reporting to the Bureau in both 1954 and 1955 experienced a 9-percent increase in juvenile delinquency cases over that period. Likewise, a trend group of 383 courts which have been reporting for many years also show a 9-percent increase in the 1954-55 period. While the increases in cases

were occurring, the child population in the 10-17 age group went up only about 3 percent. Generally, this is the age group within the jurisdiction of the juvenile court.

Not all children brought to attention of the police have committed offenses serious enough to warrant court action. The 9-percent increases in juvenile court cases may understate the actual increase in the number of juvenile delinquents in 1955. For example, the latest Federal Bureau of Investigation uniform crime report shows an 11.4 percent increase in police arrests of young persons under 18 in 1955 as compared with 1954. The FBI report is based on data from 1,162 cities.

Hopefully, joint efforts of local, State, and Federal groups can pull the delinquency rate down. Toward that end, consultants in the Bureau's Juvenile Delinquency Service Division are working with local communities and States in planning prevention and treatment programs.

Surgical Experience in Selected Areas of the United States

The era of modern surgery began only about 1875, although more than 20 centuries ago some surgical operations were performed, with much pain and suffering for the patient and an exceedingly high case fatality. Nearly all of the major developments that have made surgery safe and widely used have come since about the middle of the 19th century.

The use of surgery and related procedures in the armed forces has increased considerably in the past 50 years. However, the numbers of certain of the most frequent operations, such as tonsillectomy and appendectomy, have declined in the past 10 years.

Surveys of some years ago indicated that tonsils had been removed in roughly 40 percent of 15-year-old children and appendixes had been removed in 10 percent of 24-year-old persons.

Illness surveys of households in selected areas in the United States indicate that tonsillectomy is the most frequent surgical operation among persons of all ages combined, with surgery for accidents and appendectomy second and third. However, benign tumors except of the female genital organs had the largest percentage of cases treated surgically, with appendicitis second and congenital malformations third. In terms of five broad age groups, tonsillectomy is first in frequency in the two age groups under 15 years, second in the three age groups 15-64 years, but is ninth at 65 and over. Appendectomy is tenth in frequency under 5 years of age, third in the three age groups 5-44 years, fifth at 45-64, and is not found among the 10 most frequent operations at 65 and over. Accidents, except poisoning, were the first cause of surgery in the four age groups above 15 years, and the second cause in the two age groups under 15.

It is generally but not invariably true that

relative variation with age is greater in surgical rates per 1,000 population than in percentage of cases treated surgically.

No. 38

The accompanying summary covers the principal findings presented in Public Health Monograph No. 38, published concurrently with this issue of Public Health Reports. The authors are with the Division of Public Health Methods, Public Health Service.

Readers wishing the data in full may purchase copies of the monograph from the Superintendent of Documents, Government Printing Office, Washington 25, D. C. A limited number of free copies are available to official agencies and others directly concerned on specific request to the Public Inquiries Branch of the Public Health Service. Copies will be found also in the libraries of professional schools and of the major universities and in selected public libraries.

Collins, Selwyn D., Lehmann, Josephine L., and Trantham, Katharine S.: Surgical experience in selected areas of the United States. Data on surgical operations from periodic canvasses of households, supplemented by United States Navy reports and nationwide hospital surveys. Public Health Monograph No. 38 (Public Health Service Publication No. 473). 48 pages. Illustrated. U. S. Government Printing Office, Washington, D. C., 1956. Price 35 cents.

Among the surgical operations with rather definitely higher rates for males are those for accidents except poisoning, hernia, hemorrhoids, and ulcer of the stomach and duodenum. Among operations with definitely higher rates for women are those for cholecystitis and biliary calculus, thyroid diseases, malignant neoplasms, diseases of the bones, joints, and other organs of locomotion, and appendicitis in the young adult ages.

Major surgery was considerably more frequent among females than among males, with a peak at 30 years and with lower rates at younger and older ages. Among males, major surgery increased rather consistently with age,

with the highest rate in the oldest age group. The peak of all minor operations comes at 5-9 years of age, with only a moderately lower rate for children under 5 years.

The American Hospital Association's published report on a survey of 1949 includes an estimate of more than 9 million operations in all hospitals in the United States. However, the proportion of operations performed in long-term hospitals, such as those for mental diseases and tuberculosis, is relatively small. Estimates for short-term hospitals only, based on the association's report, indicate some 7,200,000 operations or a rate of 49 operations in short-term hospitals per 1,000 population of the United States.

Protecting Children in Adoption. Report of a Conference

Children's Bureau Publication No. 35½. 1955. 20 cents.

Of the threefold interests in every adoption—the child, his natural parents, and his adoptive parents—that of the child is paramount. This was the major conclusion arrived at in a conference of 31 national organizations of the medical, legal, and social professions considering the protection of children in adoption. Any discussion of adoption leads back to the unmarried mother, and medical, legal, and social services for the unmarried mother are the first line of defense.

Some of the points brought out were:

Placement of the child in an adoptive home involves team work of doctors, lawyers, and social workers and for this reason, placements are best made in a community-sponsored setting, by an agency authorized for the purpose.

Unmarried pregnant girls are getting less medical care and later in pregnancy than married women.

Some of the most vicious "black market" cases involve girls frightened or coerced into signing a relinquishment for their babies before or immediately after delivery, in order to get medical and hospital care.

Many doctors are unaware of existing social agencies in their communities, particularly those designed to help unmarried mothers.

New Hope for the Disabled

Office of Vocational Rehabilitation Publication VR-ISC-13. 1956. 23 pages; illustrations. 15 cents.

The major provisions of the Vocational Rehabilitation Amendments of 1954 (Public Law 565) are outlined and explained in this booklet. It lists the services available to the handicapped under the new law, summarizes the three-part Federal grant-in-aid structure established by

that law, and delineates the role of the Office of Vocational Rehabilitation in the State-Federal rehabilitation program.

The amendments to the Randolph-Sheppard Act (1954) and such related legislation as the Medical Facilities Survey and Construction Act of 1954 and the Social Security "disability freeze" amendments of the same year are discussed.

Listed are the names and addresses of regional representatives of the Office of Vocational Rehabilitation and locations of the main offices of the State vocational rehabilitation agencies from whom further information may be obtained.

This section carries announcements of all new Public Health Service publications and of selected new publications on health topics prepared by other Federal Government agencies.

Publications for which prices are quoted are for sale by the Superintendent of Documents, U. S. Government Printing Office, Washington 25, D. C. Orders should be accompanied by cash, check, or money order and should fully identify the publication. Public Health Service publications which do not carry price quotations, as well as single sample copies of those for which prices are shown, can be obtained without charge from the Public Inquiries Branch, Public Health Service, Washington 25, D. C.

The Public Health Service does not supply publications issued by other agencies.

Feminine-maternal traits, emotional stability, tolerance, and mature response to aggression or infantile conduct are among the assets to look for in nurses assigned to the care of excessive eaters and drinkers. Psychological studies offer guidelines for identifying suitable personality traits in candidates for nursing nutritional deviants.

Nurses for Alcoholics

By GIORGIO LOLLI, M.D.

THE number of hospital wards, sanatoriums, nursing homes, and clinics devoted to the care of alcoholics is growing steadily with the realization of the contemporary magnitude of this problem and the improved methods of diagnosis and treatment. At the same time the importance in our culture of other deviations in nutritional habits, such as obesity and leanness, is gaining increasing medical attention.

The establishment of facilities for the treatment of deviations in eating or drinking has naturally created a demand for qualified professional personnel. The personality traits of nurses to be assigned to services of this type are of particular consequence.

The serious responsibilities attendant upon ministering to the sick call for painstaking care in the selection and assignment of all nursing personnel. Hospital executives in the past had to rely, and not without considerable success, on their empirical experience and intuition for guidance in this function. The trend now, however, is toward application of sound and proved psychodynamic principles to the appraisal of nurse candidates. But still more can be achieved if selection is geared to the needs of treatment teams working with special classes of patients.

My discussion, therefore, centers on the importance of the emotional makeup of nurses to be assigned to a service devoted to the correction of deviant eating and drinking habits in which the approach is simultaneously medical, psychological, and social.

The extension of these principles to other types of clinical services, it is hoped, will be self-evident.

The emphasis on interactions between the nurse and the alcoholic patient should be construed only as an expression of the belief that the nurse who is able to deal adequately with the alcoholic can also deal appropriately with all patients regardless of the condition for which they need nursing care. When sick, all individuals to a certain extent revert to infantile patterns of behavior. The understanding and handling of this behavior is facilitated by knowledge about alcoholism—a condition which results from the eruption of infantile traits in adult age.

Finally, it is assumed that the importance of the nurse's professional qualifications is universally granted and needs no further emphasis here.

The suggested criteria represent an ideal conception of the nurse qualified to work in a service for eating and drinking deviants. But even if ideals seldom, if ever, can be attained in full, our constant goal should be to approach the model.

A systematic evaluation of the emotional as-

Dr. Lolli is research associate of applied physiology at Yale University, New Haven, Conn.

sets and liabilities of the nurse prior to her assignment to a particular service will weed out some candidates who would affect and be affected unfavorably by the institutional group. Of course, evaluation must continue after the nurse becomes a member of the staff. It should be an endless and creative process of mutual criticism wherein the appraisal of the newcomer by the older members is not more important than her appraisal of the group. Final decisions about long-term employability should be taken only after several months of trial.

Certainly nurses, like other members of the human race, cannot be expected to be without emotional inadequacies. However, some difficulties which are not necessarily handicaps in other professions or occupations might present a serious threat to a satisfactory nurse-patient relationship.

The emotional problems which represent a handicap in a nurse assigned to a service for deviant eating and drinking habits usually are deeply rooted and difficult to alleviate or solve. The illusion that personality changes may occur as a result of learning experiences with staff members or with patients should not be fostered. In a service of this type, time is seldom available for entirely adequate treatment of the patient. Time is never available for more than a superficial approach to the emotional difficulties of members of the staff. On the other hand, emotional problems of the staff may be swiftly magnified, or change from latency into open manifestations, as a result of exposure to an emotionally disturbing environment.

In the selection and evaluation of nurses, the concept of "compatible neuroses" is a practical one. When a new nurse is employed the composition of the staff as a whole should be kept in mind. It is desirable to visualize what effects the new member of the team will have on the older ones. For instance, some obvious handicaps in a nurse supervisor can be tolerated if other members of the team do not exhibit similar traits or are not too sensitive about them.

Excessive drinking, excessive eating, and deviant nutritional habits in general are linked with the very dawn of emotional life. Through the first nutritional experiences the first social experiences of the adult-to-be take place. Adequate hunger-linked emotions are those of love,

warmth, and mutual tenderness. The inadequate ones are those of hate, violence, and resentments in general. A mutually rewarding mother-child relation favors the development of adequate hunger-linked emotions. Conversely, an unsatisfactory mother-child relation has untoward repercussions unless outweighed by later and more favorable experiences.

When psychological and social techniques are applied to problems of nutrition and nutritional habits, uncontrollable emotions often flare up quickly and violently not only in patients but also in emotionally ill-equipped therapists. The reason for this is that the emotions linked with deviant nutritional habits are antisocial in their nature. Indeed, it may be that unconscious fears related to these emotions account for the paucity of attention given thus far to the psychological and social aspects of hunger and of nutritional habits in general.

Physical Characteristics

In a general hospital, the nursing staff of a service for nutritional deviants should be limited to women. A general hospital has male attendants available if necessary for security. Experience has shown that with properly trained and emotionally fit women nurses, with medication administered promptly and adequately, and with a response to violence which emphasizes firm and fearless tolerance, the need for restraints and for the use of force in general is practically nil.

The limitation to women nurses is based on the crucial role played by women in bringing up children, as known from time immemorial and confirmed by scientific research during recent decades. While unsatisfactory mother-child relations contribute to all cases of adult maladjustment, they are especially decisive in those directly linked to deviant nutritional habits. Conversely, healthy emotional experiences with adequate women may help to alleviate or wipe out the painful pressure of half-buried experiences with the woman who is of paramount importance in the life of every human being. This stress on the significance of an unhealthy mother-child relationship should not be construed as "criticism" of the mothers of

patients or of the patients themselves. It is simply a recognition of the fact that inadequacies of the mother-child team have far-reaching consequences.

The marital status of the nurse seems unimportant. There are countless single women who display clear-cut feminine personality characteristics, objective attitudes toward sexual behavior and its deviations, and ability to participate in a variety of mutually rewarding social relations. Because healthy attitudes toward sex problems are often entirely unrelated to sex experience in real life, inquiries about sex life are seldom important for evaluation. Such inquiries may rather be symptomatic of the problems of the interviewer than evocative of those of the candidate.

It follows that marriage or sex experience does not make feminine a woman who is not so from the start; nor will either or both solve sexual problems. The presence or absence of sexual difficulties stems psychodynamically from the presence or absence of maladjustment in the area of hunger-linked emotions. This is why problems connected with distortions of the ability to love, to relate to people, to be tender, to express warm feelings appear to be of fundamental significance.

The age of the candidate is of secondary importance, provided she is in excellent physical health.

Shared Handicaps

In a service devoted to deviant eating and drinking habits, excessive drinking and marked overweight or underweight represent obvious handicaps. Moderate overweight or underweight can be tolerated if the nurse is able to accept possible criticism from patients about her "weakness" and to use the handicap as a veiled indication that she is "not different." One of the main difficulties of the neurotic patient is his feeling that he is "different." He sometimes feels encouraged by seeing that other people who have achieved some measure of success in life also exhibit handicaps similar to his own.

If her language is clearly intelligible, a foreign accent should not disqualify a candidate. In many cases, the neurotic patient feels him-

self a "stranger" or "estranged." Contact with another "stranger" may be emotionally helpful. People sometimes share with a traveling companion, a stranger, facts and feelings which they could not share with a close friend.

The ability to express herself clearly in writing, however, is important for the nurse because of the great value of her observations, which should be recorded in detail.

With these possible exceptions, however, it must be remembered that in a professional nurse-patient relationship the emphasis should be on shared assets rather than on shared handicaps.

All that has been said thus far in no way attenuates the importance of basic professional and technical training. In addition, some knowledge or at least some specific interest in nutrition and dietetics is desirable since the attitude of the deviant patient toward food often supplies revealing clues to his emotional life.

Psychodynamic Principles

It is advisable that a candidate be interviewed separately by two members of the staff whose training and experience allow them to base an evaluation of the nurse's assets and liabilities on sound psychodynamic principles.

The following questions may be considered as a general guide for interviewers but are not intended to be used as an interview outline.

Has the candidate ever had any problem connected with the excessive use of alcohol or drugs? If so, a thorough psychiatric evaluation should be conducted before a decision is taken, even if the addiction to alcohol or drugs is no longer active. The rule that persons presently addicted to alcohol or drugs should not be considered for a position in a service specializing in eating and drinking deviations has no exceptions. For persons who were addicted to alcohol or drugs in the past, this rule could have some exceptions which only a thorough personality study of the candidate may justify.

The emotions linked with excessive use of alcohol or of drugs and those linked with nutritional deviations in general tend to be explosive. These are the emotions whose distortions lead to a variety of serious individual and social disorders, besides alcoholism or drug addiction.

Persons suffering from these emotional turmoils often have their problems fanned by exposure to patients suffering from similarly distorted emotional constellations.

The experience of Alcoholics Anonymous, an association of former excessive drinkers who help each other to keep sober, might seem to contradict this viewpoint. A deeper examination of the difference between a therapeutic relationship with patients and fellowship in Alcoholics Anonymous will prove that no such contradiction exists.

The attitude toward Alcoholics Anonymous of any service dealing with alcoholic patients should be friendly and cooperative, giving full recognition to the great contribution of this movement to the alleviation of the problem of alcoholism.

In most cases the professional therapeutic approach to the alcoholic patient is compatible with the activities of Alcoholics Anonymous. Thus, with exceptions based on psychiatric contraindications, the alcoholic patient should be encouraged to participate in the movement. Nevertheless, the fundamental differences between a professional and a nonprofessional approach must never be lost to sight. It is true that all professional as well as lay methods used to control alcoholism are based on the same process: Emotional energies tied to physical disability, psychological inadequacies, and social maladjustment, or a combination of these disorders, are liberated through the alleviation or correction of the handicaps and then used to keep the urge to drink in check. But professional approaches and the Alcoholics Anonymous method differ quite markedly in the degrees of alleviation and correction of the medico-psycho-social handicaps and even more in the techniques of achieving such alleviation or correction.

The members of a professionally trained treatment team should approach the alcoholic, as all patients, on the fertile ground of common humanity. The lines of communication with him are tacitly sustained by the assets shared with him. While the therapists take their own liabilities for granted, they do not share them with the alcoholic beyond the implicit admission of their existence.

To try to cooperate with the alcoholic on a

professional level calls for a variety of assets in the nurse. She must be able to direct an abundant, flexible, and timely flow of emotions to those areas of her personality which are challenged by the alcoholic's difficulties. For example, there is need for large emotional reserves so that the response to aggression will be tolerance, so that the wounds inflicted by hate will be healed without excessive challenge to the nurse's proper attitude. In the ideal attitude, the nurse's wishes and her ethical duties should coincide.

Emotional reserves are not ample in the alcoholic. The nurse addict is no exception even if her abstention from alcoholic beverages has been of reasonably long duration, because she needs these emotions to keep in check her own addictive urge. This situation makes it difficult for her to deal with alcoholics on a professional basis.

The alcoholic nurse, like any other addict, is able to deal with and help her fellow alcoholics on a nonprofessional basis. This is shown decisively by repeated experience in Alcoholics Anonymous, where the line of therapeutic communication between members is sustained by the shared conscious experience of a handicap (namely, addictive drinking) and by the shared unconscious experience of those guilt-laden emotions which lead to addiction. The fact is that less emotional energy is required by the alcoholic to abstain in Alcoholics Anonymous than to refrain from drinking in response to professional treatment. The more economical achievements of Alcoholics Anonymous result from the circumstance that within the framework of the movement the addictive urge to drink is kept in check by mutually potentiating group emotions whose pressure is concentrated intensely—sometimes violently—on the interplay of the two opposites: inebriety and sobriety.

A sound and adequate professional approach, on the other hand, leads to an ampler expansion and to a greater flexibility of the alcoholic's personality. The outcome is deeper: a less rigid acceptance of life in general and a more secure attitude toward the lifelong liability connected with the alcoholic problem in particular.

As already noted, professional and Alcoholics Anonymous approaches are compatible and

their combination is advisable in many cases of alcoholism. In combined approaches, the abstinence from alcohol achieved and maintained in Alcoholics Anonymous does not drain the alcoholic's emotions drastically and enables him to face a professional approach with greater chances of personal improvement.

But this fact must be borne in mind: While the alcoholic can "receive" profitably a combination of professional and nonprofessional help, only exceptional persons can give professional and nonprofessional help to the alcoholic at the same time. Yet this is the dangerous situation faced by a professional nurse who is an alcoholic in working with alcoholics as patients.

Whether or not she is a member of Alcoholics Anonymous, she is bound to share her liability with the alcoholics she nurses, either on a conscious or on an unconscious level. From this viewpoint, therefore, her line of communication with alcoholics is not professional. Yet in nursing duty she must try to establish a professional line of communication which, because based mostly on personal assets, calls for large amounts of free emotional energies. Repeated observation indicates that the nurse's attempt to reconcile professional and nonprofessional attitudes has a high liability to failure. In all likelihood, this attempt adds a new conflict to the old ones, with renewed drain on the nurse's emotional reserves. When dutybound to act professionally, either her defenses against the urge to drink weaken or an ill-concealed nonprofessional attitude takes the place of professional nursing. Dangers then arise for the alcoholic nurse as well as for the alcoholic being nursed.

The following propositions, based on fundamental principles of mental economics, summarize the above discussion:

1. In Alcoholics Anonymous and in some other lay approaches, the individual member gives the alcoholic as much help as he receives. The success of treatment is based on this equilibrium.

2. In a professional relationship, the therapist must be able and willing to give much and to receive nothing. The maintenance of the emotional equilibrium of professional personnel is the outcome of interactions between these indi-

viduals and society at large, with resulting availability of large emotional reserves for treatment purposes.

3. An alcoholic nurse, even if long sober, almost constantly faces difficulties in tolerating a situation of disturbed equilibrium in which the help she should give far exceeds what she receives.

These statements should not be construed as an attempt to demonstrate the superiority of professional treatment and professional personnel. Their aim is solely to clarify the differences between professional and lay approaches.

What is the candidate's attitude toward the emotional problems of patients? Extremes of excess interest and disinterest are equally undesirable. The adequate nurse seldom tries to elicit from patients conversation relating to emotions. However, patients often talk to her. She should be able to interrupt "confessions" which, almost intuitively, she senses to be damaging to the patient's emotional stability, insofar as the patient will later regret disclosures made in a state of turmoil.

The emphasis on emotional problems, so obvious in contemporary societies, can lead to an attitude characterized by almost total denial of body illness. The "it's all in your mind" type of nurse is not particularly helpful to patients. It hints of a grandiose and rather primitive conception of the powers of the human mind. To be aware that body and mind interact does not mean that disturbed emotions are the exclusive cause of body disorders, and certainly the nurse should not promote such an impression.

Is the candidate interested in bedside nursing? Some nurses are attracted by the scientific aspects of nursing, by theoretical discussions, and by administrative functions only because they are basically inhibited with patients. They are unable to be close to them, touch them, and so forth. Such attitudes are indicative of emotional problems which, related as they are to underlying deviant nutritional habits, are not compatible with the proper nursing of patients on a service specializing in these very problems.

Does the candidate have strong feelings of inferiority (or superiority) about the practice of nursing in comparison with the practice of internal medicine, or psychiatry, or social work?

An unrealistic hierarchical conception of professions is the symptom of unsolved intellectual and, sometimes, emotional problems. The well-trained nurse has her rightful place in a therapeutic team on an equal basis. The best qualified nurse understands the nature of this equality.

Does the candidate believe that there are higher or lower activities in nursing? The good nurse has no such illusions. The handling of a bedpan is not an activity of a "lower" quality than some administrative functions. The quality of a function is determined by the training brought to it and by the emotional attitude toward it. Strivings for power which are incompatible with ministering to the sick often underlie concepts relating to higher or lower activities in nursing and in professions in general.

Has the candidate ever worked in close cooperation with social workers? If so, has she gotten along well with them? How does she feel about social workers in general? If she has not teamed with social workers in the past, is the likelihood of good cooperation apparent?

The profession of social work has gone through changes as radical as those observed in the profession of nursing in recent years. From the handling of some apparently simple social problems, social workers have shifted their attention in part to the emotional problems of the individual. The experience thus gained has deepened their insights into the social maladjustments which are the projection of inner inadequacies. Experience has shown that an approach to social difficulties based on sound psychodynamic principles can supply to the disturbed person those corrective emotional experiences which may affect his inner equilibrium favorably and durably.

The cooperation between nurse and social worker is most helpful to any patient in the hospital and outside. In the eyes of the alcoholic, for example, the nurse often represents the temporary shelter and security of an unreal world. The social worker, on the other hand, represents the harsh realities of day-by-day life. This seems to be one reason why so many

hostilities are still polarized against the social worker. The emotional ambivalence toward maternal figures which governs the lives of many neurotic individuals, alcoholics among them, often expresses itself with love for nurse and hostility to the social worker. The nurse is often in a position to interpret the social worker to the alcoholic. Furthermore, nurse, exposed more than any other professional person to the exhausting challenges of the alcoholic, often needs the emotional support, well as the technical interpretation of the nurse-alcoholic relationship, which a skill psychiatric social worker can supply.

How does the candidate envisage the special role of the nurse in the prevention or alleviation of the emotional difficulties of patients? There is growing psychodynamic evidence that the main factor underlying emotional stability is a healthy and mutually rewarding mother-child relation. Regardless of her age, the nurse plays a maternal role for all patients and should be endowed with maternal traits. According to this viewpoint, maternal traits should be considered almost identical with feminine traits, and they are not dependent on the actual experience of motherhood. They are to be understood as the ability to tolerate and to interrupt betimes other people's pleasures and also their pains. The good mother is the one who knows how and when relief should be given to the child's pain; she knows also how and when the child's pleasures should be interrupted. In other words, she should be able to tolerate some pain in her child without guilt feelings and some pleasure without envious feelings. Besides these traits, emotional and physical stability, plus predictability of reactions to a given situation, should be considered maternal traits.

Does the candidate prefer male or female patients? There is little doubt that the ideal nurse should be maternal enough not to have preferences for male or female patients.

How would the candidate react to attempts by patients to get information about her personal life? The ability not to disclose too much about her personal life is of great importance. Usually it is linked with the ability to give some

harmless information about herself. In her contacts with the patient, the nurse should be able to keep control of the questions asked of her. This ability is definitely linked with her respect for other people and with her self-respect.

What is the candidate's attitude toward success or failure? Persons whose emotional constellations are similar to those operative in alcoholism and in other deviant nutritional habits often have a kind of "all or nothing" attitude toward success and failure. A minor error represents total failure and, conversely, a minor achievement might be fantastically magnified into a major success. The ability to see these matters in their proper perspective is best suited to the nursing of patients of this type.

How does the candidate react to aggression? Completely passive and completely aggressive reactions are equally undesirable if present all the time. Of course, occasional passivity or aggression are part and parcel of human nature. When required by the welfare of the patient, a nurse should be able to enforce discipline without experiencing guilt. Her actions should be guided by reason and not precipitated by the overwhelming pressure of her aggressive emotions.

Does the candidate exhibit harmless infantile traits? The ability to be a child occasionally and to interrupt the often painful performances of adult behavior should not be considered a handicap. Brief expressions of harmless infantile traits may greatly help a nurse to control those infantile traits which are harmful. The upbringing of many disturbed adults, among them the alcoholics, was highlighted by parental or cultural attitudes pointing to natural childhood behavior as basically "wrong" and leading to repression of harmless infantile traits.

What is the candidate's attitude toward hierarchical transmissions of authority and nonphysical violence from top to bottom? There is little doubt that authority and violence are often, even though wrongly, linked together and that retaliation for authoritarian attitudes of superiors is meted out to persons inferior in rank and, eventually, to patients.

The ideal nurse should be able to block violence at her level and to act more as a buffer than as a catalyst.

Can the candidate distinguish between a friendly attitude toward a patient and being "friends" with the patient? Can she keep sufficiently close to him and at the same time sufficiently distant from him? In a service for deviant eating and drinking habits, many patients are in good physical condition 2 or 3 days after their admission. They tend to become "friends." They attempt to engage the nurse in a close relationship which is dangerous both to them and to the nurse. The latter must have the skill to maintain the relationship on a professional level.

Does the candidate apply the disease concept to alcoholism and obesity? The alcoholic and the obese are suffering as a result of their search for excessive and forbidden pleasures. The disease connotation of their predicament is unusual insofar as the concept of disease is customarily linked with the concept of pain. Sooner or later persons in contact with alcoholics and obese individuals sense—consciously or unconsciously—that a search for forbidden and excessive pleasures, much more than overwhelming pain, is at the root of the trouble. Some professional people, nurses included, cannot accept without resentment the excessive pleasures of the addicts and react with ill-disguised hostility to the realities of the situation.

Is the candidate tolerant of the patient's lack of cleanliness? Alcoholics, especially in the early days of their hospitalization, are often unclean and unwilling to be clean. Sometimes this attitude is followed by an obsessive search for cleanliness. There is a type of woman, observed often in our culture, who was brought up with an obsessive repulsion against all that is not perfectly clean. She might feel "soiled" by the sexual experiences of marriage, and as a young mother she might be repelled by the soiled diapers of her baby. While this is not the place to discuss how and why this attitude develops, it can be stated that a rather tolerant attitude toward lack of cleanliness and an equally tolerant attempt to correct it are es-

sential in the nurse assigned to patients on a service for nutritional deviants.

Is the candidate sensitive enough to the emergent needs of the neurotic to be able to satisfy them quickly if required? Is she able to interrupt his pain swiftly when it appears to be overwhelming? On the other hand, is she free enough of impulsive traits to be able to delay the interruption of pain when it seems justified to do so in terms of long-range therapeutic plans? The attitudes explored by these questions are linked with the previously discussed maternal traits.

Is the candidate so secure as to be able to discuss her inadequacies with colleagues and superiors? If unable to cope with a given situation or with a given patient, is she able to delegate the task to a colleague? These admissions of individual shortcomings can occur only within a well-integrated and smoothly operating therapeutic team, where mutual respect is based on technical competence but even more on high standards of morality and of emotional adequacy.

Can the candidate correctly interpret sexual or apparently sexual proposals by patients? There is little doubt that some patients react to nurses with the most childish side of their personalities. Sometimes they try to touch them, eager for a physical contact which is more that of the child with the mother than of the man or woman with another adult woman or man. The correct interpretation of these attitudes is fundamental and should lead to tolerance not free from firmness.

Is the candidate willing and able to give the patient all the explanations necessary to make clear the apparently mysterious ways in which a service of this type operates? Is she a good listener? Because of the attempt to elicit corrective emotional experiences, the attitude of the treatment team often differs radically from all attitudes to which patients had been exposed in the past. Thus the service and the actions of its personnel are often interpreted as puzzling and mysterious. Nurses should have the ability

to clarify misunderstandings and define treatment goals. They should be able to listen with poise to the patient's excessive praise or criticism of other members of the therapeutic team, and be free to convey to colleagues and superiors the patient's feelings about them so that treatment may be modified accordingly.

Summary

Services devoted to patients with deviant eating and drinking habits, separately or in combination, are growing in number. The professional nurse is a most important member of the therapeutic team in such services. Available are psychodynamic principles which should be applied to the evaluation and selection of nurse candidates for services of this type.

The specific criteria suggested are intended to help in identifying both suitable and unsuitable emotional traits in the nurse seeking assignment to such a service. The chief guiding principle is that the nurse should be a woman able to function as a symbolic feminine-maternal figure. This is based on the observation that patients with deviant eating and drinking habits usually experienced some disturbance in the early mother-child relationship, with resulting distortion of hunger-linked emotions, and that this maladjustment can be alleviated through healthy emotional contacts with adequate woman figures.

Among the most desirable specific characteristics, therefore, are: stable emotional makeup; feminine-maternal traits (not dependent on age or sexual experience); ability to cooperate in a treatment team with social workers particularly; acceptance of the patient's condition, in spite of its origin in pleasure-seeking activities (eating, drinking), as one requiring professional treatment; and ability to respond to the patient's occasional need for immediate relief from pain, or occasional aggressive and infantile conduct, without counter aggression and with appropriate mature behavior.

Nurse candidates who themselves have experienced addiction to alcohol or drugs require special psychiatric evaluation.

Payments by the State welfare agency for clients needing care in nursing or boarding homes lag behind actual costs, and this, in turn, keeps many such homes from improving their standards to meet the State health agency requirements.

Costs of Care of Aged and Infirm Residents in Florida Nursing and Boarding Homes

By FERNE HOBSON BRITT, R.N., and MARGARET H. JACKS, A.B.

COSTS OF CARE in nursing and boarding homes for the aged and infirm were studied cooperatively by the Florida State Department of Public Welfare and the Florida State Board of Health in January, February, and March 1955. Both departments are interested in the development of adequate resources to care for persons whose physical and medical needs cannot be met in their own homes.

The Florida State Board of Health was given the legal responsibility of licensing and maintaining standards in nursing and boarding homes for the aged and infirm in 1953. Many of the residents in such homes receive aid through one of the public assistance categories administered by the Florida State Department of Public Welfare. Both agencies and the general public were aware that the licensing program of the State board of health and the accompanying attempt to raise standards in such homes were increasing the cost of operation. The increase in cost had been reflected in charges for care. There had been no paral-

lel increase in the amount of public assistance grants. As a result, there was a widening gap between the charges made by nursing and boarding homes and the amount recipients of public assistance were able to pay. Lack of information led the two agencies to study the cost of care in nursing and boarding homes.

In this joint study, the two agencies did not contemplate establishing a cost of care scale to be imposed on nursing and boarding home operators or establishing the amount which they should charge for care. We hoped that information on the cost of a standard of care that assured minimum adequacy could be established for the use of agencies and interested communities as a guide to the amount of public money needed to provide adequate care for recipients of public assistance and to provide adequate compensation for operators. We felt that the cost of acceptable care for the average patient should exclude extra services which various homes may offer at extra cost. The term "cost" in this study included a fair return on investment.

At best, the services at a nursing home are difficult to evaluate inasmuch as many of the usual yardsticks of achievement or failure cannot be used to measure the intangibles. We could tabulate types of activities and physical facilities. However, the tender loving care, the

Mrs. Britt is a consultant nurse with the Florida State Board of Health. Mrs. Jacks is supervisor of old age assistance and aid to the blind, Florida State Department of Public Welfare.

little "extras," the quality and effectiveness of the specific nursing activities which influence the health and happiness of the residents are more difficult to appraise. Fortunately, such elements do not necessarily contribute to costs. With these limitations in mind, the summary of our findings may be helpful.

Plans for the Study

We recognized from the beginning that the study would be time consuming. Also it would be virtually impossible to make as complete a study as would be desirable because of staff limitations of both agencies. However, we thought that, through the cooperation of the two agencies at both State and local levels and with the cooperation of the operators of the homes, some valid information might be obtained.

The cost of care fell into two logical divisions, overhead expenses and services. Because of the varying needs of the person served as well as the difference in required equipment and facilities, costs in nursing homes vary decidedly from costs in boarding homes. Therefore, in the study, the average cost of acceptable care per patient in nursing homes and in boarding homes were determined separately.

In the study, for purposes of clarification and administration, nursing homes were defined as homes for the care of patients not requiring hospitalization. Many of the patients or residents of these homes have a chronic disease or are medical or surgical patients requiring further institutional care after hospital discharge.

Boarding homes for the aged were defined as being essentially for domiciliary and custodial care for aged persons, some of whom may require medical and nursing supervision.

The per patient cost of ordinary services, distinct from nursing care and housekeeping services, was determined and added to the average overhead charges.

In order to obtain cost figures for services, the nursing home operator was asked for data on the types of nursing and housekeeping services, the amount of time consumed in giving a particular service, and the number of times a specific service was performed.

Two schedules were developed for gathering

this information. Both contained questions on nursing and housekeeping functions. Schedule A was devoted primarily to questions on nursing functions with a few housekeeping items. Schedule B was primarily filled with housekeeping items, but a few questions on nursing functions were included. The forms were devised in this manner because, in many instances the size of a home and the number of the staff determined the types of services given by the workers in that particular home. Also, in some homes the nurses were doing the work ordinarily performed by maids, and the untrained workers were giving the nursing service. Because of this overlapping of services, each worker was asked to fill out both "A" and "B" for each of the 14 workdays of the study.

The time spent on services as reported by the homes on the schedules was compared with current State nursing home standards and with hospital standards. Although nursing homes could not be expected to provide services equal to hospital standards, such a comparison was useful in evaluating the difference in the quality of care. The same comparison was applied to boarding homes.

The average wage for nursing service was computed from the average wage for registered nurses, licensed practical nurses, aides, and orderlies throughout the State of Florida. The frequency with which licensed practical nurses, aides, and orderlies were hired to provide nursing service in ratio to the number of registered nurses hired to provide this service was established from personnel information obtained from the homes. The wages paid to the three classifications of employees was then averaged in the same ratio, and the hourly figure thus arrived at was accepted as the average hourly wage paid for nursing service. After the average wage and time figures were obtained, the number of hours of service provided was multiplied by the hourly wage to arrive at the average cost of service in a home.

To obtain figures on overhead costs, a schedule was prepared for entering detailed information on expenditures by the operator for capital outlay and fixed and semifixed charges of operation. This schedule C requested identifying information, the average number of patients, and minimum and maximum rates

charged. In addition, it asked for information on the property occupied; the number and types of buildings; the age of the buildings; if owned, the value, amount of mortgage and mortgage payments, taxes, insurance, maintenance, and depreciation; if rented, the monthly rent. This schedule also asked for costs of licenses, liability insurance, utilities, medicine and medical supplies, transportation, laundry, cleaning supplies, and telephone service. Information on the cost of replacement of furnishings and the expenditure for personnel was also requested. Although the cost of nursing personnel was specifically eliminated as an operating cost since the per patient cost of service was determined and included elsewhere, questions on all personnel were included on schedule C to obtain information on the average wage paid to nursing personnel. Wages paid to cooks, maids, maintenance men, and others, with the exception of nursing personnel, were considered as personnel costs in operating the home.

A simple form C supplement was also devised to help nursing home operators to keep a record of daily expenditures. Use of this form was not mandatory but was available to operators who did not use regular accounting systems. This part of the study was conducted during three winter months in order to include the cost of fuel, since, in most sections of the State, heat is not required during other months.

On the advice of two investment experts, 12 percent of total investment in real estate and 20 percent of investment in equipment were accepted as the annual cost for shelter and equipment, respectively.

Recognizing that financing costs of real property and equipment as well as maintenance costs of the home might remain fairly static, and that the cost of shelter, licenses, insurance, telephone service, and utilities were fixed charges which would change very little regardless of the number of beds occupied, the per capita cost of these items was derived by dividing the totals by the bed capacity of the home. Food, laundry, medical supplies, and transportation of patients were semifixed charges which would vary according to the number of beds occupied, and the per capita cost was derived by dividing those totals by the average number of patients receiving care during the period of the study.

In addition to capital outlay cost and fixed and semifixed charges, the total included an item for wages for the owner-operator. The amount was determined by the proportion of time spent on various duties as administrator, nurse, chauffeur, and so on. If the operator had responsibility for the home and also served as one of the nursing personnel, compensation for the time spent on administration was included but nothing for nursing service as that service was recognized elsewhere. If the operator gave full time to administrative and supervisory responsibilities and his services were not recognized elsewhere, an amount was entered to compensate him for full-time employment. If the owner were not the operator but merely had a financial investment in the enterprise, no salary was entered for him.

Originally, all homes licensed by the State board of health were to be asked to participate. At the time the licensing program was initiated, the State board of health had issued licenses to all homes which applied without regard to current standards. In the 1½ years after the licensing program had begun, there had been a concerted effort on the part of the State board of health staff to help the temporarily licensed homes to meet the standards. When the study was planned, many licensed homes had not met all requirements but in the majority there had been at least a degree of improvement and most homes were providing adequate care. We hoped that a large majority would participate in the study and that, in any event, there would be representation of all types of homes: large and small; nonwhite and white; urban, semi-urban, and rural; expensive and inexpensive.

Since the study was a joint venture, the local staffs of both the county health units and of the Florida State Department of Public Welfare were asked to meet with the operators to explain the aims of the study, the use of the schedules, and the procedures, and to help them to develop the data.

Because of the nature of their respective fields, the local health department staff was asked to work with the operators on service costs, and the local welfare department staff was asked to work with the operators in determining the cost of operating the home. When

the study was ended, completed schedules were collected and compilations made by State offices.

Procedures Followed

At the time of the study there were 274 licensed homes. A letter from the State board of health was sent to the operators of these homes explaining the plans for the study and asking if they wished to participate. Exactly one-half of the licensed homes, or 137, replied in the affirmative.

Of the 137 homes signifying their willingness to participate, a number did not follow through because of the operators' unwillingness to do the necessary clerical work; a few were excluded because the limitation of time prevented the necessary personal interview with operators. More homes were omitted because a county health department did not have the necessary personnel to participate and support the program. A few were dropped because the operator and her personnel found it impossible to grasp the significance of the information desired for the survey.

In the final group of homes included in the study, the number of nursing homes and boarding homes were in almost identical relationship to the number of licensed homes in the State, and every type of home originally planned for was included.

Following the prearranged program, a public health nurse and a welfare visitor went together on an initial visit into each home to discuss the study and to plan with the operator for completing schedules. During their subsequent visits, the nurse each week and the welfare worker each month, discussed and answered questions about the schedules, and, finally, collected the completed schedules.

Nursing Home Service Costs

An average of 2.3 hours of daily nursing service per patient was reported on the schedules from nursing homes. This ranged from 3.2 hours of nursing care in the better-equipped homes to a minimum of 1.2 hours of nursing care per patient in the less well-equipped homes.

Information obtained from the hospitals

throughout the State indicated that 3.4 hours of daily nursing care was the average standard in private and public hospitals.

The personnel required by the Florida State Board of Health standards for nursing homes would provide 2.8 hours per day for each patient, if followed.

To reconcile the discrepancy in these three standards, we consulted with members of the nursing profession and staff members of several hospitals. The consultants agreed that the hours of nursing service as reported by the homes was substandard and that a minimum of 2.6 hours per day of nursing service must be provided for acceptable care.

The average wage paid for registered nurses in Florida was found to be \$240 per month; for licensed practical nurses, \$155; and for aides, orderlies, and attendants, \$125 per month. When these wages were averaged together in the same ratio as personnel were employed to provide nursing service, the wage paid for nursing service averaged \$0.85 per hour.

Multiplying this figure by the 2.3 hours of nursing service reported by the homes, the per patient cost of nursing service averaged \$58.65 per month.

The compromise figure of 2.6 hours of nursing service with the same hourly wage, established the cost of adequate nursing service at a minimum level of \$66.30 per month.

Using the 2.8 hours included in the State board of health standards for nursing homes, the \$0.85 hourly wage established the cost of service at \$71.40 a month.

The amount of nursing care provided in a hospital could be accepted as the care required for the acutely ill. The 3.4 hours of nursing service (hospital standards) at the \$0.85 hourly cost of service established the minimum cost of service for acutely ill persons at \$66.70 a month.

Boarding Home Service Costs

In the boarding homes, an average of 1.07 hours of nursing service per day was given to each patient. This was slightly lower than the Florida State Board of Health standards which require that personnel in boarding homes provide 1.4 hours of care. The consultants

agreed that no standard providing for less care was adequate.

In determining the average wage of persons providing care in boarding homes, only the wages paid to licensed practical nurses and aides and orderlies were considered; their average wage, in the ratio of the numbers employed in boarding homes, was \$0.75 an hour.

At the hourly wage of \$0.75, the 1.07 hours of service in the homes reporting established the cost of service at \$24 per patient per month. The \$0.75 hourly wage with the State board of health standard of 1.4 hours of service per day established the cost of adequate service to the patient in a boarding home as \$31.50 per month.

Operating Costs

The original plan was to obtain completed schedules on operating costs for three consecutive months. When the completed schedules were evaluated, we found that some homes submitted figures for only 1 month, but indicated that the figures were average. These schedules were included. In some cases, 2 months' reports were received. In the majority of the homes, the 3 months' reports were averaged together to arrive at the average monthly cost for items included.

The only figure reported comparable with an acceptable standard was the figure for cost of food. Information from the nutrition staff of the State board of health established the per patient cost of food in the average nursing home at \$25.50 per month. The average amount spent for food was reported by the nursing homes as \$24.50, and by boarding homes as \$24.15.

Generally, a wage for the operator was not reported except when the operator did not act as one of the nursing personnel. From operators' wages reported and the comparative amount of time the operator spent on administrative duties, we determined that \$15 a month should be included as a per patient wage for the operator who spent full time on his duties as administrator. A \$5 per patient monthly cost was included for wages to the operator who acted in dual capacity as operator and nurse. There were no boarding homes

where the operator did not also give service; in those homes the \$5 per patient figure was included as the salary for the operator.

Findings

The final compilation on a per patient monthly figure for capital outlay and fixed and semifixed charges of operating nursing homes was \$89. Included in this total was the wage paid to the owner-operator.

The overhead plus the monthly cost of 2.3 hours of patient daily nursing service as reported by the homes, \$58.50, equalled \$147.50, the average per patient cost of care in the nursing homes.

Adding the overhead to the monthly charge for 2.6 hours of nursing service, \$66.30, the compromise standard, established \$155.30 as the cost of adequate service in a nursing home.

These figures refer to the average patient. Acutely ill or extremely disturbed patients require additional nursing service. We felt that 3.4 hours of nursing service should be the minimum in such circumstances; thus the cost of care for acutely ill persons was established as \$176 a month.

Overhead in boarding homes, compiled by the same method as for nursing homes, was \$75.50. Adding this to the cost of 1.07 hours of care, \$24, resulted in \$99.50 as the reported cost of residence in boarding homes.

Using the same overhead figure of \$75.50 and substituting \$31.50 as the cost of the 1.4 hours of care required by State board of health standards established the cost of care in a boarding home with adequate custodial supervision at \$107 per patient.

The figures for nursing and boarding home care should be adjusted upward to insure adequate amounts being spent for food, in line with information that adequate food cannot be purchased for less than \$25.50 per patient.

The cost of care in the larger boarding and nursing homes was somewhat smaller than cost of care in the same type of home providing for fewer patients. In the nursing homes with a capacity of 10 or more patients, the average cost was \$140. In nursing homes providing care for fewer than 10 patients, the average cost was \$167. A similar but less marked

difference was obtained in figures from boarding homes. In those boarding homes caring for 10 or more patients, the cost totaled \$95. In boarding homes caring for fewer than 10 patients, the cost was \$104.50. Charges made by the nursing homes ranged from \$60 a month (the amount which can be paid from public assistance grants) to a maximum of \$400. Charges made in boarding homes ranged from \$40 to \$239 a month.

Conclusions

Under the present Florida State Board of Health standards, 2.8 hours of nursing care are recommended for nursing homes. If the compromise figure of 2.6 hours of nursing care per person per day is accepted as the minimum amount of care needed to provide basic, essential nursing service, then the nursing homes which give an average of only 2.3 hours of nursing care fall below an acceptable standard. If the homes participating in the study are representative of all the nursing homes in the State, 77 percent of the homes provide a substandard amount of nursing service, and 23 percent provide adequate or above standard care. In the boarding homes, 69 percent fail to meet acceptable standards, and 31 percent meet or exceed the standards established by the State board of health as sufficient to provide adequate custodial care.

The total responsibility for the quality or quantity of care cannot be placed on the nursing home operators. Nursing home operators face many difficulties in the operation of these homes. Scarcely an operator in the State has not experienced difficulty at some time or other in obtaining qualified help. The lack of trained help is shown in the study. A large number of untrained employees provide different types of care to patients. Many nurses do not wish to work in homes giving care to the aged and chronically ill. Hospitals that can offer adequate salaries and satisfying working conditions appear to be absorbing desired trained personnel.

The many nursing activities in nursing homes provided largely by aides and other untrained help are reflected in the quality as well as the quantity of nursing care. Many capable wom-

en, despite their lack of preparation, are doing a worthy job. Lack of finances is one of the major reasons they are not prepared. There are 18 schools for the preparation of the professional nurse and 12 schools for the preparation of the licensed practical nurse in Florida. A plan for financial assistance for trainees would enable more women to take advantage of these facilities and would increase the number of available trained nursing personnel.

The financing of a nursing home requires initial investment and a continuing expenditure of time and money by the operator. To meet these financial demands and to insure a reasonable return on the investment, the operator must charge and receive a reasonable amount in payment for services. The figures from this study reflect a cost far above the sum currently provided by most State or local welfare funds for indigent patients.

Most of the homes adjust charges for the care of private patients who demand and are able to meet the cost of extra services. This is to be expected.

The figures established by the study, however, do not include the costs of these additional services. The cost of \$156 for nursing care and \$108 for boarding care reflects a standard of care which provides for only those services which are basic. To provide for any less results in suffering by the patient who must be cared for under substandard conditions.

Figures were not obtained on the proportionate number of patients who receive public welfare grants and the number of private patients in the homes. Many operators stated that they refuse to take patients for \$60 a month. In general, those same homes are the homes where standards are as high or higher than the standards required by the State board of health.

Apparently, this gap between the actual cost of care and the amounts which the recipients of public assistance can pay is a contributing factor in the low standards maintained in many homes.

It was not possible during the short period of the study to secure data on medical care provided in the homes, the number of patients now attending a clinic or those being seen regularly by a doctor. There has not been a systematic referral system developed between the homes

and the hospitals which provide clinic care to the patients. How much the establishment of such a referral system would reflect in additional and more adequate nursing care being required for patients is not known.

In addition to the cost of basic care in a nursing or boarding home and the problem of providing adequate medical supervision, there is a vital need for recreation and rehabilitation services for the aged and chronically ill. Only

a few homes provide a program of recreation or rehabilitation.

It is obvious from the findings of this study that additional help must be given in raising the standards of physical care and in providing additional services for patients who must be cared for in an institutional setting. It is equally obvious that with present payments for care and current limitations of available personnel it is not possible to appreciably raise standards.

An Important Date

Each month your health department and many hospitals, laboratories, schools, clinics, and homes receive a copy of PUBLIC HEALTH REPORTS, mailed to arrive on the 20th, or even earlier, depending upon geographic location of the subscriber.

Its pages carry timely research reports, analyses of current trends, new methods, concepts, and ideas, and topical reviews for the busy scientist, teacher, or public health worker. Capsule coverage of important public health meetings, like those of the American Public Health Association, help the PHR reader.

You can have your personal copy promptly. Use the subscription blank on the inside back cover. Let the 20th of each month be an important date for you, too.

Heart Disease at Mid-Century

By PAUL D. WHITE, M.D.

IN THIS YEAR, still in the middle of the twentieth century, our hearts control much of our destiny. Diseases of the heart and arteries are responsible for a very large percentage of the illnesses and deaths in this country, even among children and young and middle-aged adults.

Despite the slowness with which we are moving in our efforts to meet this challenge, really great progress has been accomplished in several directions:

Cardiovascular syphilis has been almost wiped out as a result of the remarkably successful campaign for the prevention and early recognition and treatment of syphilis itself and the introduction of the antibiotics, especially penicillin. Once cardiovascular syphilis made up nearly 25 percent of all cases of heart disease; now it is well under 1 percent.

Rheumatic heart disease, at one time the most common type of all, is on the wane. In New England 30 years ago, it led all the other kinds of heart disease in prevalence. Now it is a poor third. This reduction is associated with

several factors, notably (a) the improvement in living conditions and (b) preventive measures to control infection by the hemolytic streptococcus, largely responsible for this type of heart disease.

Another advance of importance, achieved through remarkable development in surgery and splendid teamwork between physician and surgeon, is the rescue of a great many patients—thousands and thousands, afflicted with severe mitral stenosis. It is to be hoped that, with the reduction of rheumatic heart disease, much less need will exist in the future for this magnificent surgery of today.

Subacute bacterial endocarditis, formerly called malignant because it killed almost 99 percent of all patients, is now not only curable in about 75 to 80 percent, but can probably be prevented in many patients by the use of antibiotics. Moreover, as we reduce the incidence of rheumatic and congenital heart disease, subacute bacterial endocarditis will decline.

Other infections responsible for serious heart diseases in the past also are becoming scarce. Included among them is diphtheria, which used to be fatal in many patients because of its effect on the heart.

Chronic constrictive pericarditis, once incurable, is clinically reversible now in more than half the patients by the use of surgical techniques developed in the past 25 years. Its fundamental cause, tuberculosis of the pericardium, should be, along with tuberculosis in general, steadily on the road to oblivion so that in another generation there should be little or no demand for such surgery.

Dr. White is emeritus clinical professor of medicine, Harvard University Medical School. He is also executive director of the National Advisory Heart Council and president of the International Society of Cardiology. The accompanying comments were presented at the American Heart Association's dinner for opening the National 1956 Heart Fund Campaign, January 31, in Chicago.

Ten leading causes of death, 1955

Death rate	Estimated rates per 100,000 population	Percent of total
352.0	Diseases of heart	37.9
147.6	Malignant neoplasms	15.9
106.6	Vascular lesions of CNS	11.5
55.6	Accidents	6.0
39.8	Certain diseases of early infancy	4.3
27.5	Pneumonia (except of newborn) and influenza	3.0
19.4	General arteriosclerosis	2.1
15.2	Diabetes mellitus	1.6
11.9	Congenital malformations	1.3
10.8	Cirrhosis of liver	1.2

Source: National Office of Vital Statistics, Public Health Service, Monthly Vital Statistics Report, vol. 4, No. 13, May 28, 1956

Thyrotoxicosis used to be the cause of heart disease in an occasional patient. Now, as a result of early recognition and much more satisfactory treatment of thyrotoxicosis, heart disease from this cause is rare.

Cor pulmonale, both acute and chronic, is on the wane as a result of the lower incidence of pulmonary embolism and the control of dusty air, indoors and out. How much harm smog may be doing is not known.

Even one of the more prevalent and serious kinds of heart disease, hypertensive heart disease, is now beginning to yield to treatment. The vigorous attack made on hypertension in the last two decades through surgery, diet, and the use of drugs has been extremely helpful.

Problems for the Future

We haven't done much about the most important heart disease of all, namely, coronary heart disease, except that we can recognize it more readily than we used to, we know a little more about its course, and we can treat it more intelligently.

Congenital heart disease also remains as a great problem for the future. We have learned little about it, and we cannot prevent it. We know that it can be caused by german measles in the mother during the first 3 months of pregnancy, but there are certainly other factors and causes not yet discovered. The one bright spot with respect to congenital defects is that a number of them can be corrected, in whole or in

part, by surgery. This in itself is, of course, no small achievement.

Thus, progress against heart disease is still far from its goal: prevention of new cases and adequate treatment of heart disease where it exists. The major cardiac problems are congenital defects, high blood pressure, and coronary heart disease. I think, too, we must take cognizance of the problem of apoplexy, or to use the longer term, cerebral vascular disease, which afflicts so many people with or even without high blood pressure. Also, there is much to be done about the prevention of disease of the larger arteries, the aorta and the blood vessels of the legs in particular. Arteriosclerotic disease of the kidney is still another problem that needs much further study for the sake of prevention, recognition, and treatment. We have found that it tends to be one of the great hazards of old age. Perhaps with its control, healthy old age can be prolonged.

The need for applying, to the best of our ability, the knowledge we already have, in private practice and in community programs, deserves special attention. For example, it is known that the great majority of cardiac patients not only can work but should work. Physical exercise and mental activity are two of the best therapeutic measures for patients with heart disease. Like persons who are crip-

pled in other parts of their bodies, cardiac patients perform some of the best work in the world.

In the study of heart disease, the epidemiological approach offers opportunities not otherwise available. This approach needs to be used more extensively, not only in our own country but world wide. The study of the prevalence of the various kinds of heart disease in different groups and communities here and in foreign lands can be valuable both for the people of other countries and for those in this country. International teams should cooperate in the study of heart disease so that the situations in one country can be compared with those in another.

Heart programs are among the most important health campaigns ever planned. Though we may be not one-third of the way toward the maximum achievement, the years ahead are filled with promise. We can protect the hearts of the young and the middle-aged with something much more substantial than the casual advice to "take it easy," even if that is good advice, which it may not always be. If we pursue these programs with vigor, 10 years from now, I venture, we shall have remarkably reduced heart disease in the young and middle-aged throughout the world.

Staff College Course for Nurses

The fourth Federal Civil Defense Administration Staff College course for nurses is scheduled to be given at the FCDA National Headquarters, Battle Creek, Mich., September 24-28, 1956.

Special emphasis will be given to educational and training programs for nurses in civil defense.

Priority for enrollment will be given to nurses associated with schools of nursing, inservice training programs of hospitals, industry, schools, public health agencies, nursing organizations, and State or local civil defense offices. There is no tuition fee.

Nurses may obtain application forms from their local or State civil defense office, or by writing to the Staff College, National Headquarters, Federal Civil Defense Administration, Battle Creek, Mich.

Group A Beta Hemolytic Streptococcus and Rheumatic Fever in Miami, Fla.

By MURRAY M. STREITFELD, Ph.D., MILTON S. SASLAW, M.D.,
and SIMON D. DOFF, M.D.

A LONG-TERM STUDY of the relationship of group A beta hemolytic streptococcus to rheumatic fever in Miami, Fla., was undertaken to explain why rheumatic fever seems less severe and occurs less frequently in Miami than reported elsewhere (1-3). A survey of the prevalence, type, and virulence of this group of organisms and the immunological response of the host over a period of years, we felt, would yield a pattern of host-organism relationship which might enable us to answer this question.

Our preliminary observations from February through May 1953 revealed the presence of group A beta hemolytic streptococcus in the throats of 16.3 percent of 343 school children in Miami (4) at some time during the 4-month period. This suggested that factors other than the mere presence of this group of organisms are responsible for the apparent difference in rheumatic fever in Miami's "tropical" climate

(5, 6), as compared with other more northerly geographic localities.

Since the preliminary findings were limited to a 4-month study period, we continued to culture samples from the throats of these children for group A beta hemolytic streptococcus from October 1953 through May 1954 in order to obtain a more comprehensive picture of the prevalence of this group of bacteria in the Miami area. In addition, antistreptolysin O studies were performed to determine whether the strains of group A beta hemolytic streptococcus isolated evoked a systemic response. This is a report of the bacteriological and immunological data obtained during this 8-month period and a discussion of the significance of the results.

Material and Methods

Throat Culture Studies

During the 8-month period, October 1953 through May 1954, pairs of throat swabs were taken monthly from an average of 351 children attending grades 1 and 2 in three schools in Miami, for a total of 2,809 pairs of swabs. In all, 417 children were included in the study, and each child's throat was swabbed an average of 6.7 times.

The children came from grades 1 and 2 in the same three schools previously studied (4); these represented a low-income white group, a middle-income white population, and a mixed-income Negro group. The sample selected, though not truly random, represents the stable

Dr. Streitfeld is bacteriologist and Dr. Saslaw is director of medical research at the National Children's Cardiac Hospital, Miami, Fla. Dr. Doff is director of the division of heart disease control of the Florida State Board of Health, Jacksonville, Fla.

This study was supported in part by funds from the Florida State Board of Health and grant H-1738, Public Health Service. Providing technical assistance at the National Children's Cardiac Hospital were Alba Colon, Nettie E. Cudequest, and Ruth Rosen.

part, by surgery. This in itself is, of course, no small achievement.

Thus, progress against heart disease is still far from its goal: prevention of new cases and adequate treatment of heart disease where it exists. The major cardiac problems are congenital defects, high blood pressure, and coronary heart disease. I think, too, we must take cognizance of the problem of apoplexy, or to use the longer term, cerebral vascular disease, which afflicts so many people with or even without high blood pressure. The fourth Federal Civil Defense Administration Staff College course for nurses is scheduled to be given at the FCDA National Headquarters, Battle Creek, Mich., September 24-28, 1956.

Special emphasis will be given to educational and training programs for nurses in civil defense.

Priority for enrollment will be given to nurses associated with schools of nursing, inservice training programs of hospitals, industry, schools, public health agencies, nursing organizations, and State or local civil defense offices. There is no tuition fee.

Nurses may obtain application forms from their local or State civil defense office, or by writing to the Staff College, National Headquarters, Federal Civil Defense Administration, Battle Creek, Mich.

in tables 1, 2, and 3. The highest percentage of positive cultures (15.4 percent) was obtained in May 1954 (table 1), the lowest (6.2 percent) in December 1953. The average percentage of positive cultures was 11.4 percent for the 8-month period and 6.2 percent for the 4-month period. The earlier 4-month study, of course, is not comparable quantitatively to the later 8-month survey.

Group A organisms were found at least once in 126 children, or 35.9 percent of the average of 351 children studied in the 8-month period

(table 2). This percentage was about the same for each of the three schools (table 3), and no significant differences were found in the number of isolates from first grade children compared with second graders. The average monthly recovery rate of group A beta hemolytic streptococcus was 8.0 percent.

Nine types of group A beta hemolytic streptococcus (table 4) were encountered in October 1953 through May 1954, in contrast to strains of type 12 only (with the exception of a single strain of type 28) in February through May

Table 1. Grouping of beta hemolytic streptococcus isolated from 2,809 throat cultures in 417 children over an 8-month period, October 1953-May 1954, and comparison with February-May 1953, Miami, Fla.

¹ Nongroupable.

school population. A high-income group was omitted because such a group does not maintain year-round residence in Miami and therefore does not permit long-term observation. The first graders were new to the study. Only 189 second graders who had participated the year before, as first-grade students, were included. Written permission of the parents had been obtained for each child.

In all, 1,050 children were registered in grades 1 and 2 of the three schools. Thus, the 417 children in the study represented 39.7 percent of the total registration in these two grades.

As in the preliminary study (4), throat swabs were taken in duplicate from all children present in school during the mornings set aside for this phase of the work. The same technician performed all the swabbings within a 2-hour period. All the collected swabs were taken promptly to the laboratory for immediate plating. One swab was streaked on a plate of Difco blood agar base (DBAB) and the other on a plate of Difco neopeptone heart infusion agar (DNHI); both media were enriched with 4 percent defibrinated sheep's blood. DNHI had been used in May 1953 as an adjunct to DBAB to insure recovery of the highest number of positive isolates. Incubation, isolation, and subculturing of the cultures were carried out as previously. Grouping and typing were performed again under the supervision of Dr. Elaine Updyke at the Streptococcus Laboratory, Communicable Disease Center, Public Health Service.

No attempt was made to obtain cultures from the throats of children absent on the days set for study. However, the school nurses checked the reason for absence in most instances.

Antistreptolysin O Studies

Blood samples were taken simultaneously with throat swabs every 2 months. The serums were kept in deep freeze until the end of the study, when antistreptolysin O titer determinations were made using a single lot of commercial Difco Bacto streptolysin O reagent. In all, 996 serums from 356 children were tested by standard procedure (7) at titers of <12, 12, 50, 100, 125, 166, 250, 333, 500, 625, and 833.

The bacteriological findings were classified into four categories as follows:

1. Serums from children whose throats yielded no beta hemolytic streptococcus or group B beta hemolytic streptococcus only. The latter group was included in this category because it does not produce streptolysin O (8).

2. Serums from those with nontypable strains of group A beta hemolytic streptococcus, either alone or in combination with other groups of beta hemolytic streptococcus.

3. Serums from children bearing typable strains of group A beta hemolytic streptococcus found at least once, either alone or in combination with other groups of beta hemolytic streptococcus.

4. Serums from children from whom group C or group G beta hemolytic streptococcus, or both, were recovered. Some strains of these groups produce streptolysin O (8).

In order to correlate and evaluate our bacteriological and serologic findings, an antistreptolysin O index (9) was established for each bacteriological category. The antistreptolysin O titers were assigned numerical rank from 1 to 11, respectively. The index was calculated according to the following formula:

Where R=numerical rank and S=number of samples for the particular rank:

Antistreptolysin O index=

$$\frac{(R_1 \times S_1) + (R_2 \times S_2) + \dots + (R_{11} \times S_{11})}{\text{Total samples per category}}$$

Average peak titers were calculated for each of the four bacteriological categories and for the total number of children studied. The peak titer for each child was the highest antistreptolysin O level obtained during the study.

The antistreptolysin O index has the advantage of overcoming excessive weighting caused by small numbers of samples at high titer levels. Average antistreptolysin O titers are included for comparative purposes because average computations of titers are in common usage.

Results

Throat Culture Studies

The groups and types of beta hemolytic streptococcus isolated from the throats of the children studied from October 1953 through May 1954, together with a summary of the findings for February through May 1953 (4), are shown

tures isolated on each of the two media used during the 8 months of the study showed that had a single culture plate been used we would have failed to recover approximately one-third of the total beta hemolytic streptococci and one-third of the group A organisms isolated. Both media were found to be equally effective in the isolation of beta hemolytic streptococci and of group A organisms. Present studies are being conducted to determine the effect of streaking the initial swabs on three plates.

Numbers of colonies of beta hemolytic streptococcus present on initial plates were recorded. Approximately one-fifth of all children with group A organisms recovered from their throats yielded more than 10 colonies on at least one

of the 2 initial plates; four-fifths had under 10 colonies.

Some strains that showed alpha hemolysis on initial surface plating were found to give beta hemolysis on subsurface culturing. The failure of these strains to produce streptolysin S probably explains the absence of surface beta hemolysis, which depends on the formation of this lysin. On the other hand, subsurface beta hemolysis, the criterion for classifying a beta hemolytic streptococcus, is due to the formation of the oxygen-labile streptolysin O (10).

Table 6 lists children from whom the different groups of beta hemolytic streptococcus were isolated, according to the number of throat specimens cultured for each child. Higher

Table 3. School distribution of group A beta hemolytic streptococcus, October 1953–May 1954, Miami, Fla.

School	Average number of children studied	Children with group A		Total number of cultures taken	Total group A isolates	
		Number	Percent		Number	Percent

Ao=nontypable group A beta hemolytic streptococcus; At=typable group A beta hemolytic streptococcus.
¹ The 45 typable cases in these 4 columns are listed as total new isolates in table 4.

1953. Although type 12 predominated during the 8-month study and occurred in 26 instances, types 1 and 4 also were found frequently, type 1 in 17 and type 4 in 13 cases.

In 60 children, group A organisms were recovered 2 to 7 times during the 8-month period (table 5). Both typable and nontypable organisms were isolated from 8 children. In 8 other children, a strain of group B, C, F, or G beta hemolytic streptococcus was isolated, as well as a typable or nontypable strain of group A.

Of the 58 children who had beta hemolytic

streptococci in their throats during the pilot study, only 29 could be included in the 8-month study. Of these 29 children, 21 (72 percent) continued to show the presence of beta hemolytic streptococci in their throats; 14 (48 percent) maintained the same type or group of organism; 5 had a different organism, and 2 had two different organisms. Eight were negative for beta hemolytic streptococcus. Fourteen of the twenty-four children with group A streptococcus in the first year continued to carry the same group of organisms in the second year.

A comparison of the number of positive cul-

percentages of positive cultures recovered from those children from whom smaller numbers of swabbings per child were taken may reflect absenteeism due to streptococcal throat infections. However, the numbers are too small within each category to be interpreted finally.

Antistreptolysin O Studies

Table 7 shows the antistreptolysin O titers in relation to bacteriological categories, and gives the average antistreptolysin O titer and

index for each bacteriological category. The antistreptolysin O index (4.6) of children with group A beta hemolytic streptococcus was elevated over the index (3.5) of children from whom no beta hemolytic streptococcus or only group B was recovered. Although children with typable strains of group A had a higher average antistreptolysin O titer than those with nontypable strains of group A, the antistreptolysin O index was the same for both. Children from whom groups C or G organisms, or both

¹ Withdrawn from study.

Ao=nontypable group A beta hemolytic streptococcus (ABHS); A1=type 1; A3=type 3; A4=type 4; A12=type 12; A28=type 28; A33=type 33; and A44=type 44 ABHS; B, C, F, and G each designates a beta hemolytic streptococcus group.

Neg.=negative; Abs.=absent; Trans.=transferred.

schools in Dade County, Fla., further indicate that this rate can be applied to the entire school population in the 6- to 9-year age group.

The streptococcal recovery rate must be considered minimal since no throat swabs were taken from absentees and no data on therapeutic use of antibiotics were available. If many of the absences were due to streptococcal infections, collection of throat swabs from these children during their absence might have yielded a higher recovery rate.

Furthermore, the rate must be considered minimal for other reasons. The technical impossibility of swabbing the faucial surfaces in their entirety resulted in the loss of some organisms. The use of dry swabs as well as the time required to collect all specimens, return them to the laboratory, and plate them might have resulted in death of some streptococci. The mechanics of preparing streaked plates undoubtedly led to some loss. Some organisms probably failed to survive after plating, while others, lacking in streptolysin S, did not cause surface hemolysis, and therefore these colonies might have escaped recognition. Subsurface plating initially would have demonstrated organisms containing streptolysin O, but such a procedure was impractical in our study.

Finally, our observation that the use of a single initial throat swab and plate would have caused the recovery rate to appear 25-35 percent lower than it actually was leads us to speculate that had third, fourth, or even more initial throat swabs and plates been used, the rate might have been higher.

Despite these valid objections to accepting our recovery rate as a true index of incidence or prevalence, the figures observed provide irrefutable evidence of the minimum frequency of occurrence of beta hemolytic streptococci.

Before drawing any conclusions as to the significance of the presence of group A beta hemolytic streptococcus in such a large proportion of the children studied, let us consider three possibilities regarding the host-organism relationship in these cases.

1. Is group A beta hemolytic streptococcus a harmless inhabitant of the throat with no systemic effect on the host? We cannot definitely answer this question as yet. Our studies thus

far lead us to believe that in most cases this is not so. Antistreptolysin O determinations showed higher average titers and an increased percentage of high titers associated with the presence of group A beta hemolytic streptococcus, suggesting that the organisms found in the throat evoked a systemic response. School attendance records, observations at the time throat swabs were taken, and nurses' followups indicated that about half of the children with positive cultures had respiratory illnesses (colds, "virus infections," tonsillitis, bronchitis, pneumonia, ear infection) either immediately before, during, or after the time that their throat specimens were cultured. These records did not include data on therapy.

2. Does the finding of group A beta hemolytic streptococcus reflect an infectious process (clinical or subclinical)? If an elevation in antistreptolysin O titer is indicative of previous clinical or subclinical streptococcal infection, our overall serologic findings would support this hypothesis.

3. Does the finding of group A beta hemolytic streptococcus signify the postinfection carrier state? The postinfection carrier state may have existed in 24 of the 126 children from whom group A organisms were isolated. Streptococci were recovered from these 24 children during October 1953, the first month of the study, and we have no way of determining whether these were new isolates or whether they had persisted from previous months. In the remaining 102 children (26 percent) from whom streptococci were isolated for the first time after their throat cultures had been negative for at least 1 month, we may exclude the postinfection carrier state. The persistence of streptococci in the throats of children over a period of months may reflect either a continuing infectious process or the postinfection carrier state. Our current studies, in which we are attempting to correlate more closely the serologic with the bacteriological findings, may clarify this point.

It is significant that despite repeated recovery of beta hemolytic streptococci from their throats, none of the children in the three schools studied developed active rheumatic fever, nor was there a single case of scarlet fever.

Table 7. Antistreptolysin O (ASO) titers of 996 serums taken from 356 children, by bacteriological category of child

¹ I. Children with no beta hemolytic streptococci or group B only; II. children with nontypable strains of group A beta hemolytic streptococcus, either alone or in combination with other groups; III. children with typable strains of group A beta hemolytic streptococcus at least once, either alone or in combination with other groups; IV. children with group C or group G beta hemolytic streptococcus, or both.

² 25.6 percent.

³ 7.7 percent.

groups, were isolated demonstrated approximately the same average antistreptolysin O titer and index as those with nontypable group A streptococcus. Analysis of the peak antistreptolysin O titers indicated that the average peak was lowest in children from whom no beta hemolytic streptococci were isolated, higher in those with group C and group G or nontypable group A streptococcus, and highest in children with typable strains of group A organisms.

The number and percentage of serums with titers of 166 and above, as well as those of 250 and above, are also listed for each of the 4 bacteriological categories. Where beta hemolytic streptococci were isolated, the percentage of high titers was greater than where these organisms were not recovered.

Discussion

The present study confirms our preliminary impression (4) that the low incidence of rheumatic fever, when diagnosed in conformity with Jones' criteria (11), and of rheumatic heart disease in Miami, Fla. (1), cannot be attributed to the infrequency of group A beta hemolytic streptococcus in this "tropical" climate. The finding of group A beta hemolytic streptococcus in the throats of 126 of the total of 417 children (30.2 percent) or 35.9 percent of the average monthly attendance figure of 351 children in three Miami schools during the 8-month period, October 1953 through May 1954, demonstrates that those organisms were common in this area. Additional studies now in progress in 900 children attending the first three grades in 36 other

Departmental Announcement

Edmund Baxter has been appointed as the regional director of Region III, Department of Health, Education, and Welfare, Charlottesville, Va.

Mr. Baxter has approximately 20 years of Government service, mostly with the Department of Health, Education, and Welfare and its predecessor agency. He has served for the past 3 years as consultant for special institutions in the Office of the Secretary. Prior to that, he was in charge of the program under which allotments of critical materials were made to schools, colleges, hospitals, and welfare institutions.

Mr. Baxter is a graduate in public administration of the University of Louisville. He served during World War II as a naval officer in the Pacific.

A number of investigators (12-16) have implicated group A, types 12 and 4, beta hemolytic streptococcus in the pathogenesis of glomerulonephritis. None of the children, in either our pilot or present study, from whom type 12 or type 4 group A beta hemolytic streptococcus was isolated, developed clinical glomerulonephritis. The "nephritogenicity" of these strains is considered elsewhere (4, 17). The predominance of type 12 in both of our studies indicates that this type was common in the schools studied and did not represent an isolated "epidemic" in February through May 1953, when it was the only type recovered.

We are still investigating the significance of groups B, C, and G beta hemolytic streptococci in relationship to illness in Dade County. Groups C and G evoked at least one type of systemic response, as evidenced by the higher average antistreptolysin O titer of children harboring these groups of streptococci compared with that of children from whom no beta hemolytic streptococci or only group B streptococci were recovered.

When considered in terms of the rheumatic fever picture in Miami, Fla., our observations suggest that the low rate of the disease cannot be attributed to the following:

1. Infrequency of group A beta hemolytic streptococcus.

2. Difference in groups or types of beta hemolytic streptococci compared with those encountered in other areas.

3. Lack of immunological response of the host, as determined by antistreptolysin O titers.

The answer probably lies "in some alteration in the pattern of the etiological relationship presumed to exist between group A beta hemolytic streptococci and rheumatic fever" (4) other than variations in incidence, frequency, or type of organisms.

Variations in the virulence of the organism or differences in degree or pattern of the host's immunological response to the organism may be responsible for the low rheumatic fever rate in Dade County, Fla. Also to be considered in the pathogenesis of the disease is the possible role of a virus-streptococcal combination (18). All of these factors probably are influenced by geography and climate.

Summary

1. Throat swabs were taken monthly from October 1953 through May 1954 from 417 children in grades 1 and 2 in three schools in Miami, Fla. In all, 2,809 pairs of throat swabs were collected, representing an average of 6.7 swabs per child and 351 children per month.

2. Group A beta hemolytic streptococcus was isolated from the throats of 126 (35.9 percent) of the children at least once during the 8-month period.

3. Nine types of group A beta hemolytic streptococcus were isolated; in order of frequency, these were types 12, 1, 4, 3, 28, 31, 33, 23, and 44.

4. One hundred eighty-nine children who participated in a pilot study (February through May 1953) were carried over into the present program. Of these, 29 had harbored beta hemolytic streptococci in the pilot study. Twenty-one (72 percent) continued to carry streptococci in their throats; 14 (48 percent) had the same group of beta hemolytic streptococcus or the same type of group A organism.

5. Sixty children harbored group A beta hemolytic streptococcus in their throats on more than one occasion during the 8-month study. Twenty-six of these children had participated in the pilot study; 8 had been positive for group A organisms; an additional child had carried a nongroupable organism.

6. The percentage of positive isolates was approximately the same in the first graders as in the second graders.

7. Antistreptolysin O titers of children with groups A, C, and G beta hemolytic streptococcus were higher than those of children from whom no beta hemolytic streptococci or only group B were recovered.

8. The findings are discussed from the standpoint of several possible types of host-organism relationship.

9. None of the children from whom group A beta hemolytic streptococcus was isolated developed active rheumatic fever or scarlet fever, nor was clinical glomerulonephritis noted among any of the children, including those from whom a strain of type 12 or type 4 group A beta hemolytic streptococcus was isolated.

10. The low rheumatic fever rate in Miami, Fla., is discussed in view of these findings.

shelter from the wind. When *Anopheles* enters a house, it nearly always enters from the leeward side.

He learned that malaria mosquitoes avoid sunlight, rarely bite in the daytime, and then only in the shade. Their larvae are easily frightened and for long intervals remain hidden under water.

He noted that the puddles in hoofprints of cows and horses were important producers of certain *Anopheles* species; that green algae on water surfaces harbored larvae; that some areas produced a species of *Anopheles* only at certain times; that thousands of mosquitoes traveled from the swamps to human settlements each and every night; and that the *Anopheles* seemed to know exactly where it wanted to go.

He disproved the theory that anophelines were brought into towns by strong winds blowing from the marshes. When traps set in a vacant house failed to attract mosquitoes, LePrince and his men, by sleeping there, proved that it was the mosquitoes' strong sense of smell and their liking for the odor of human perspiration that brought them to their victims. He observed that some people were more attractive to *Anopheles* than others.

He learned that mosquitoes were carried on the clothing of passengers who traveled for long distances in trains at night; that they would remain on a man's coat during a stiff wind; that they gained entrance to screened dwellings by being carried in on dark clothing, where they rested undetected.

Screening of dwellings in Gatun, Colon, Panama City, and elsewhere along the 40-mile stretch of the canal was carried out on a scale never before attempted anywhere. When LePrince ordered the headquarters of the Canal Commission screened, the architect, who was new to the tropics, joked about the fuss made over the screening and delayed following the order. A month later he was dead of yellow fever.

LePrince not only faced indifferent cooperation. He was ridiculed. His destruction of Santa Ana Park in Panama City aroused public hostility. He was called an insect chaser and a crackpot. But he permitted no obstacle to dampen his ardor for his task.

The long-awaited details of the yellow fever

and malaria campaigns were revealed to the world in 1916 when LePrince published "Mosquito Control in Panama." This report on what he had learned in the Canal Zone and Havana was to remain a bible for mosquito control workers for many years. It is still a classic guide on environmental controls for certain mosquito species.

In the introduction to LePrince's historic work, Dr. L. O. Howard, then chief of the Bureau of Entomology, United States Department of Agriculture, recalled a conversation with Gorgas and LePrince before they left for Panama.

Howard had asked the general whether he would send specimens of all Panama mosquitoes to the bureau for naming. The general replied: "I will assign Mr. LePrince to see that it is done." Whereupon, LePrince remarked, "I will have to do it soon, Doctor, for in a year or so there will be no mosquitoes there."

Another anecdote about LePrince was supplied by the renowned Public Health Service epidemiologist, Dr. Leslie L. Lumsden. Lumsden told of sitting behind LePrince at a meeting where someone reading a paper on malaria was quoting liberally from LePrince's book without attribution. Lumsden asked LePrince how he liked having his "stuff" used without credit. The old man's eyes shone. "Just fine, because then I know he thinks it's good."

LePrince was equally famous for his malaria successes in the United States. He continued his war against the mosquito from Public Health Service headquarters in Memphis. His brilliant achievements in the Caribbean had convinced the Service that malaria could be controlled economically in the continental United States.

During World War I, LePrince had charge of malaria control in 28 Army and Navy installations in the eastern and southeastern United States. His methods of mosquito control resulted in a malaria rate in the Army during World War I that was less than 1 percent of the rate in the Spanish-American War. The control achieved by LePrince and other Service engineers in the postwar period anticipated the industrial development of the southern States.

The Public Health Service loaned LePrince

LePrince, Malaria Fighter

WITH HIS DEATH on February 10, 1956, at the age of 80 in Memphis, Tenn., Col. Joseph Albert Augustin LePrince ended his long fight against malaria and yellow fever. A Public Health Service sanitary engineer since 1914, he began his campaign against vector mosquitoes in 1901, in Havana, as a civilian assistant to Maj. Gen. William Crawford Gorgas. At a time when many still doubted the evidence adduced by Carlos Finlay, Dr. Walter Reed, Sir Ronald Ross, and others, LePrince insisted on all-out mosquito control. Thanks in large part to his pioneer services, malaria is no longer a disease of economic importance in the United States.

On learning of the death of LePrince, Assistant Surgeon General Mark D. Hollis, chief engineer of the Public Health Service, said:

"Joseph LePrince received many honors during his lifetime, but knowing him as I did, I am sure that his greatest pride came from the knowledge that his work helped to wipe out some of the deadliest scourges the world has ever known. He is a great and true inspiration to those who carry on his work today."

LePrince achieved international acclaim as the right-hand man of Gorgas in the control of tropical diseases in Cuba and the Panama Canal Zone while the canal was under construction. His name will be remembered in Mexico, Puerto Rico, and other parts of Central America as one who came to serve his fellow man and served him well. He was a practical humanitarian who left the world deeply in his debt.

Son of the man posthumously honored as the father of the motion picture, LePrince was born August 3, 1875, in Leeds, England. He came to this country at the age of 12. In 1901, 3 years after his graduation from Columbia

University with civil engineering and master's degrees, he boarded ship for Havana, Cuba, on a 60-day assignment that was to last 14 years. President Theodore Roosevelt had given Gorgas full power to make the mosquito-infested island safe for our occupation forces after the Spanish-American War.

In Cuba, LePrince directed the actual work that changed Havana from a death trap of yellow fever to a tourist mecca. Within 3 months, with 2 inspectors, and at a cost of less than \$5,000, he eradicated yellow fever by eliminating mosquito-producing sources. In the process, he conducted basic studies that were to serve generations to follow.

From 1904 to 1914, LePrince, as chief sanitary inspector of the Isthmian Canal Commission and as public health officer in Panama, applied his Cuban experience to rid the "Big Ditch" of tropical diseases. In an intensive 14-month engineering campaign, he and his field men charted rainfall curves, traced watercourses, drained waterholes, converted marshes, removed jungles, and attacked propagation areas with oils and larvicides. At the same time, he was busy organizing fumigation brigades and trying to win the cooperation of householders and local authorities.

A byproduct of the campaign was a series of brilliant ecologic experiments by LePrince on the flight range and breeding habits of the mosquito which contributed to the virtual elimination of the vector of yellow fever, *Aedes aegypti*, and of the anophelines, carrier of the malarial parasites.

LePrince discovered that anopheline mosquitoes will sometimes travel a mile though a half mile is their usual flight. He found that "Madam Anopheles," as he called his foe, seeks

Mosquitoes and Encephalitis *in the* Irrigated High Plains of Texas

By FRED C. HARMSTON, B.S., GEORGE R. SHULTZ, B.C.E.,
RICHARD B. EADS, Ph.D., and GEORGE C. MENZIES, M.S.

THE OCCURRENCE of human and equine encephalitis in the High Plains of northwestern Texas during 1940-50 and, particularly, the increased prevalence among humans in 1952 aroused the interest of local, State, and Federal public health officials. The possible relationship between conditions associated with the expansion of irrigation and the increase in encephalitis virus infections led to cooperative investigations in the Texas High Plains by the Public Health Service and the Texas State Department of Health during 1953-54.

Irrigated cropland on the Texas High Plains increased from 250,000 acres in 1940, to 1,860,000 acres in 1950 (1). Deep wells are the principal source of irrigation water for this area; the effluent from municipal sewage treatment plants is also used in some localities. The spectacular expansion of irrigation has caused

major changes in the population, in agricultural practices, and in the economy of the region.

Records of the Texas State Department of Health and those of the Animal Disease and Parasite Research Branch, Agricultural Research Service, United States Department of Agriculture, show that cases of human and equine encephalitis were reported from irrigated sections of the Texas High Plains during most years of the period 1940-54. Outbreaks of the disease in humans occurred in 1952 and 1954, when 23 and 32 cases, respectively, were reported; 16 cases were reported in 1944 and 11 in 1953. The reported equine cases ranged from 3 in 1942 to 26 in 1944; 25 cases were reported in 1952.

Preliminary surveys were made in the vicinity of Lubbock and Plainview during the period August-October 1953 to obtain information on mosquito populations and the factors involved in their production. These surveys indicated that mosquito problems of public health significance occurred in the Texas High Plains and that the problems were related to both agricultural and municipal use and disposal of water.

In 1954, detailed entomological-engineering investigations were conducted throughout the season in representative areas of the Texas High Plains to determine: (a) the kinds and relative abundance of adult mosquitoes in urban and rural localities; (b) the frequency with which mosquitoes were infected with encephalitis

Mr. Harmston, a biologist, and Mr. Shultz, a sanitary engineer, are with the Logan Field Station Section of the Communicable Disease Center, Public Health Service, Logan, Utah. Dr. Eads is in charge of the entomology section, bureau of laboratories, Texas State Department of Health, Austin.

Mr. Menzies died in January 1956 of rabies, probably contracted during the course of bat rabies investigations. At the time of his death he was senior entomologist, entomology section, Texas State Department of Health.

to Mexico in 1923 to develop malaria control in the oil fields. In 1927 he directed malaria control activities in the Mississippi River area for the American Red Cross. In 1935 he became consultant on malaria control to the Tennessee Valley Authority. He was called back to the Caribbean area in 1938 to assist the Puerto Rican Government in a serious malaria outbreak. In 1940, a year after his retirement from the Public Health Service, he helped solve malaria control problems resulting from the building of dams on the upper Mississippi River.

As the world grew to appreciate his efforts, LePrince received many honors. He held the greatly prized Ross Medallion awarded by the London School of Tropical Medicine. He received an honorary doctorate of science from Southwestern at Memphis in 1945. In 1951 the National Malaria Societies chose him to receive the first Joseph Augustin LePrince Award,

named for him and bestowed on him because of his outstanding accomplishments in malaria control.

LePrince died in the Public Health Service Hospital in Memphis. He is survived by his widow, the former Julia Mercedes Lluria, of Havana, and by his son, four daughters, five grandchildren, and one great-grandchild.

LePrince closed his 1916 classic report with a prophetic statement, made in 1911 by James Bryce, Ambassador from England to the United States:

"In modern times most of the events of highest ultimate significance have been discoveries in the realms of nature or inventions in the realm of industry; and their magnitude is seldom known at first. Little was said of the discovery that mosquitoes are the carriers of yellow fever and the intermittent fevers, yet what immense consequences are already seen to flow from the determination of that fact!"

Training in Insect and Rodent Control

Training courses in insect and rodent control are being offered in Atlanta, Georgia, during September, October, and November 1956, by the Training Branch of the Communicable Disease Center, Public Health Service. These courses are based on the extensive experience of the Communicable Disease Center in investigations and operations in the vector control field and are primarily for personnel of Federal, State, and local health departments. Training in both the laboratory and the field is included, designed to give a working knowledge of the control of insects and rodents affecting the health and well-being of man.

A course in insect control, which gives principal attention to the control of mosquitoes, flies, and other insects occurring in and around homes and food-handling establishments, is scheduled for September 17-28, 1956.

Training in rodent control, October 1-12,

includes instruction in the control of domestic rodents and rodentborne diseases.

A course covering mosquito control will be given November 5-9, 1956.

A special advanced 2-week course in the biology and identification of arthropods of public health importance is scheduled for December 10-21, 1956. This course, which uses the extensive insect collection of the Communicable Disease Center, is particularly useful for entomologists and biologists and others interested in proper identification of arthropods of public health importance such as flies, fleas, ticks, and mosquitoes.

Other courses in insect and rodent control are scheduled for March, April, and May 1957.

Interested persons should apply through their organizations to the Chief, Training Branch, Communicable Disease Center, Public Health Service, 50 Seventh Street NE, Atlanta 23, Ga.

Figure 1. Seasonal abundance of adult female mosquitoes collected at rural and urban sites, Plainview and Hereford study areas, Texas High Plains, 1954.

were sampled by means of standard New Jersey light traps. Eleven traps, 5 urban and 6 rural, were operated from dusk to dawn at Plainview, Abernathy, Hereford, Hale Center, and Kress.

To determine the kinds and relative abundance of mosquitoes that attack man in the evening, biting collections were made at weekly intervals from July 20 to October 12 near the light trap sites in the town of Plainview and surrounding rural areas. The collections were made during 3 consecutive 15-minute periods beginning at sunset. Mosquitoes were caught by means of a killing tube or aspirator from the exposed legs of the collector. In contrast to the landing rate observations which are frequently made, these collections included only mosquitoes which had actually started to bite.

To obtain mosquitoes for encephalitis virus recovery tests, females of *Culex tarsalis* and other species were collected from diurnal resting shelters in urban and rural areas of Hale, Lubbock, and Swisher Counties from June 22 to October 26. The mosquitoes were collected

with an aspirator and transferred to small bobbinet cages. They were held overnight and then shipped alive by air express to the State health department laboratory in Austin, Tex. The cages containing the live mosquitoes were enclosed in an insulated cardboard carton along with two frozen gel units for cooling purposes. Shipping techniques were adapted from those described by Brennan and Mail (3).

The mosquitoes invariably arrived at the laboratory in good condition after a 4-hour trip from Plainview. Upon arrival, they were anesthetized, identified, macerated, and suspended in buffered broth. The suspension was inoculated into infant mice, young adult mice, or day-old chicks. Suspicious material was inoculated into guinea pigs from which blood specimens were taken 21 to 30 days later and tested by complement fixation for western equine, eastern equine, and St. Louis encephalitis viruses.

Detailed mosquito production studies were made between April 20 and October 29 on plots

viruses; (c) the specific conditions that resulted in mosquito production; and (d) the causes and possible corrections of these conditions.

The Texas High Plains

The High Plains of Texas cover approximately 20,000 square miles in the northwestern part of the State. They extend southward from the Canadian River Valley to the Pecos River Valley, a distance of about 200 miles. The region is bounded by an abrupt escarpment on all sides except the south, where it merges gradually into the lower, eroded plains bordering the Pecos River Valley. This vast tableland rises above the adjoining country by heights ranging from 50 to 300 feet. Its elevation above mean sea level varies from about 4,400 feet in the northwest to less than 3,000 feet in the southeast. The surface is flat to gently undulating, and has a generally uniform slope toward the east and southeast, averaging about 10 feet per mile.

Numerous playas, a few low hummocks, and small stream valleys provide the only prominent natural land features. Of these, the undrained natural depressions, or playas, are by far the most significant. The playas are scattered rather uniformly over the area, averaging about one per square mile. They range in size

from less than 10 to more than 2,000 acres, and average 20 to 30 feet in depth. The playas are usually dry during the winter months but may be flooded during the growing season by surface runoff and irrigation waste water.

The climate of the region is typically semi-arid, characterized by a dry atmosphere, hot summers, short, cold winters, and a large proportion of sunny days. The annual rainfall averages about 20 inches, with nearly three-fourths occurring during April through September. Evaporation losses are estimated at 99 percent of the average annual rainfall (2).

The irrigated area within the Texas High Plains comprises nearly 15,000 square miles and extends approximately 140 miles south from Amarillo. The predominant soil types throughout the irrigated areas are fine sandy loams and clay loams, both of which readily absorb water and therefore afford good vertical drainage. These soils are very productive under irrigation. The principal field crops are grain sorghum, cotton, small grains, alfalfa, and pasture. Irrigated truck crops, including potatoes, onions, and lettuce, are grown in some sections.

mosquito production studies were made in the following habitats associated with municipal sewage disposal: (a) the sewage lagoon at Abernathy, (b) the oxidation ponds at Petersburg, and (c) the sewage polluted streams at Plainview and Tulia.

Adult Mosquito Populations

The relative abundance of the major mosquito species collected in 5 urban and 6 rural light traps is presented in table 1. A total of 256,508 females, representing 16 species, was taken during 1,269 trap-nights from April 26 to October 28. The average nightly collection of all species was 202 for all locations combined, 335 at Plainview, 34 at Hereford, and 92 for the other four localities together.

A total of 37,322 female mosquitoes was collected in the 5 urban traps. Of these, the predominant species were *C. tarsalis*, 50 percent; *Aedes nigromaculis*, 19 percent; *Culex quinquefasciatus*, 11 percent; and *Psorophora signipennis*, 9 percent. Of 219,186 females taken in the 6 rural traps, *A. nigromaculis* comprised 44 percent; *C. tarsalis*, 24 percent; and *P. signipennis*, 22 percent.

Figure 2. Mosquito production by habitat and source of water, Plainview study area, Texas High Plains, 1954.

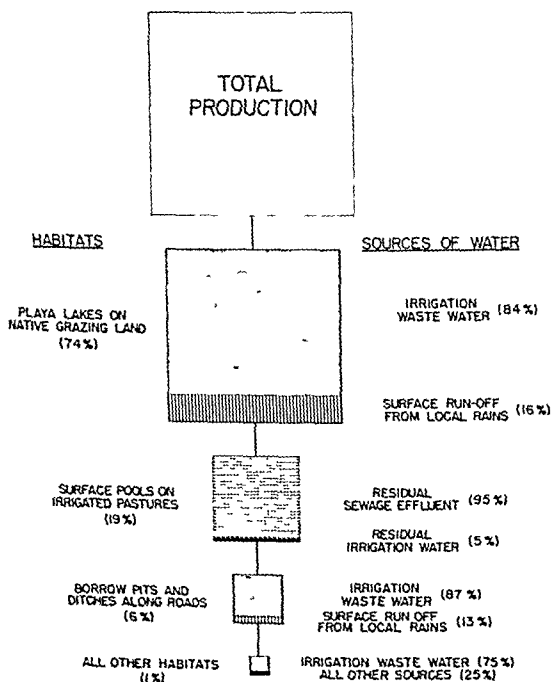

Figure 3. Mosquito production by habitat and source of water, Hereford study area, Texas High Plains, 1954.

The average nightly collection of all species in the rural traps was 357, as compared with 57 in the urban traps. The average collection per trap-night and the seasonal distribution of the major species for both urban and rural sites at Plainview and Hereford (the two principal study areas) are shown by weekly periods in figure 1.

The relative abundance of biting mosquitoes collected at weekly intervals on human hosts in the town of Plainview and in surrounding rural areas is shown in table 2. Of 2,404 mosquitoes taken in 98 collecting periods of 15 minutes each, *C. tarsalis*, the primary vector of western equine encephalitis, *A. nigromaculis*, and *Aedes vexans* were the principal species at both rural and urban sites. At the rural sites, the average attack rate for all species combined was 34 mosquitoes per period, and at urban sites, 15 mosquitoes. Both *A. nigromaculis* and *A. vexans* are severe pest mosquitoes and have been found naturally infected with western equine encephalitis (4, 5); in the laboratory they have been found to be efficient vectors of encephalitis virus (6, 7).

located in the vicinity of Plainview and Hereford. These plots were generally representative of irrigated areas in the Texas High Plains. At Plainview the study plots consisted of 22 sections (one square mile each), which included parts of the town and the surrounding agricultural area where diversified field crops were grown under irrigation. Sorghum and cotton were the principal crops and together comprised 77 percent of the total irrigated area (9,095 acres) on the plots. The combined acreage of alfalfa, small grains, pasture, corn, and Sudan grass accounted for the remaining 23 percent of the irrigated area. A small amount of pastureland on these plots was irrigated with treated sewage effluent. At Hereford the study plot included an area of approximately 6 square miles in which field and truck crops were grown under intensive irrigation. Sorghum and small grains were grown on 63 percent of the total irrigated area (3,395 acres) on the study plot, and truck crops including potatoes, lettuce, and onions covered 34 percent. Small acreages of cotton and alfalfa were grown under irrigation on the remainder of the plot. The furrow method of irrigation was employed on 82 percent of the irrigated cropland on the Plainview plots and on 94 percent of the irrigated acreage on the Hereford plot. Maps of

the study plots were prepared showing the location and types of mosquito breeding places, location of wells and irrigation distribution systems, field boundaries, field acreages, crops, and methods and direction of irrigation.

Potential mosquito breeding places were arbitrarily classified into five types: playa lakes, surface pools, irrigation laterals, borrow pits and roadside ditches, and stream margins. All temporary water areas on the study plots were sampled for mature larvae and pupae following each flooding. The permanent and semipermanent water areas were sampled once each week. Each water area was sampled with a pint-size, white-enamel dipper; the number of dips taken was proportionate to the extent of the breeding area. When mature larvae were present, representative samples were collected for identification. During each inspection, the data obtained included: (a) the average number of fourth-instar larvae and pupae per dip, (b) an estimate of the total water area, (c) an estimate of the breeding area, and (d) the source of water.

In order to evaluate the relative mosquito production potential of the various habitats on the plots, production indexes were determined by use of the following formula:

Production index = (average number of fourth-instar larvae and pupae per dip) × (breeding area in acres).

In addition to the detailed investigations on the plots at Plainview and Hereford, weekly

with only 13 percent for the Plainview area. Waste water from irrigated fields accounted for 45 percent of the total mosquito production.

On the Plainview study plots, 36,510 larvae, comprising 12 species, were collected and identified (fig. 4). The most abundant species were: *C. tarsalis*, 44 percent; *A. nigromaculis*, 36 percent; *P. signipennis*, 6 percent; and *A. vexans*, 5 percent. Other species collected in smaller numbers included *Aedes dorsalis*, *Aedes sollicitans*, *A. pseudopunctipennis*, *A. punctipennis*, *C. quinquefasciatus*, *Culiseta inornata*, *Psorophora ciliata*, and *Psorophora discolor*. *C. tarsalis* was found in all types of habitats except irrigation laterals and was the predominant species in playa lakes, surface pools on pastures irrigated with sewage effluent, and the margins of the sewage polluted creek. *A. nigromaculis* was common in all habitats except the margins of the sewage polluted creek.

On the Hereford plot, 6,099 larvae, representing 5 species, were collected and identified (fig. 5). The principal species were: *C. tarsalis*, 65 percent; *A. nigromaculis*, 22 percent; and *P. signipennis*, 11 percent. These species were found in all types of habitats. Small numbers of *C. inornata* and *P. discolor* were also collected.

Mosquito Production and Sewage Disposal

Mosquito breeding occurred in all habitats associated with sewage disposal that were studied (table 4). The playa used as a sewage lagoon at Abernathy was by far the most important from the standpoint of total mosquito production. The entire flow of effluent from the Abernathy sewage treatment plant was often diverted for irrigation, which prevented the formation of a permanent lake in the playa. This resulted in marshy conditions in the playa which were very favorable for mosquito production.

The oxidation ponds at Petersburg consisted of a series of cells constructed with steep banks. Prolific production of mosquitoes occurred in densely vegetated portions of cells which were only partially filled because of low flows of effluent. In the cells which operated at normal level, mosquito production occurred only along the vegetated banks. The percentage of total water area that produced mosquitoes in the constructed ponds was much lower than for the natural playa at Abernathy. Mosquito production also occurred along the vegetated margins of the sewage polluted streams at Plainview and Tulia.

Table 4. Larval mosquito data collected from habitats associated with municipal sewage disposal, Texas High Plains, April 20–October 29, 1954

¹ Larval inspections made weekly when water was present. ² Production index=(average number fourth-instar larvae and pupae per dip)×(breeding area in acres); seasonal production index=summation of production indexes for entire season. ³ Includes *Aedes sollicitans*, *Anopheles punctipennis*, and *Psorophora signipennis*.

Encephalitis Virus Isolations

From June 22 to October 26, 4,733 female mosquitoes were collected and subsequently processed for encephalitis virus isolations (table 3). Included were 3,324 *C. quinquefasciatus* in 17 pools, 1,315 *C. tarsalis* in 15 pools, 52 *Anopheles punctipennis* in 6 pools, and 42 *Anopheles pseudopunctipennis* in 2 pools. Western equine encephalitis virus was isolated from 4 pools of mosquitoes: 39 *C. tarsalis* collected in restrooms at the city park in Plainview, Hale County, June 29; 80 *C. quinquefasciatus* collected in shrubbery and concrete pits at the sewage treatment plant, Lubbock, Lubbock County, July 27; 118 *C. tarsalis* collected at the same time and place as the *C. quinquefasciatus*; and 51 *C. tarsalis* collected from restrooms at the city park in Plainview, September 7.

Mosquito Production on Study Plots

Data obtained from the Plainview study plots are summarized graphically according to type of habitats and source of water in figure 2. According to seasonal production indexes, approximately three-fourths of all mosquito production on the plots occurred in playa lakes

Figure 4. Species composition of mosquito larvae collected from various aquatic habitats, Plainview study area, Texas High Plains, 1954.

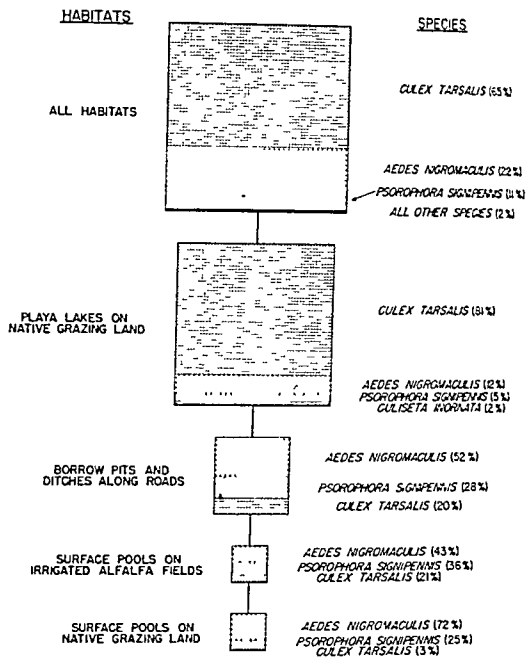

Figure 5. Species composition of mosquito larvae collected from various aquatic habitats, Hereford study area, Texas High Plains, 1954.

on native grazing land. About 20 percent of the mosquito production occurred in surface pools on irrigated pastures; of this production, 95 percent was on the pasture irrigated with sewage effluent. The only other significant breeding places were borrow pits and ditches along roads, which produced 6 percent of the total. Waste and residual irrigation water accounted for 69 percent of all mosquito production on the Plainview plots, residual sewage effluent (on pasture) 18 percent, and surface runoff from local rains 13 percent.

On the Hereford study plot, as in the Plainview area, about three-fourths of the mosquito production during the season occurred in playa lakes on native grazing land (fig. 3). Roadside ditches and borrow pits accounted for 17 percent of the mosquito production. Surface pools on irrigated alfalfa fields and on native grazing land were the only other sources of mosquitoes on the plot, each producing 4 percent of the total.

Surface runoff from local rains was the principal source of water in habitats on the Hereford plot (fig. 3). It accounted for 55 percent of the seasonal production index, as compared

Surveys in two areas contribute additional evidence that no hazard of cumulative toxic fluorosis is associated with the use of fluoridated water containing 1 p.p.m. fluoride. Within 1 week, the concentration of fluoride in the urine equaled that in the drinking water for adults. For children, the period of adjustment was considerably longer.

Urinary Fluoride Levels Associated With Use of Fluoridated Waters

By I. ZIPKIN, Ph.D., R. C. LIKINS, D.D.S.,
F. J. McCLURE, Ph.D., and A. C. STEERE, B.S.

PREVIOUS studies have demonstrated a close correlation between the concentration of fluoride in the urine and the fluoride occurring naturally in drinking water (1,2). Only a limited quantity of data is available, however, concerning the urinary excretion of fluoride added to a municipal water supply (2-4).

The authors are with the Laboratory of Oral and Biological Chemistry, National Institute of Dental Research, National Institutes of Health, Public Health Service. Dr. Zipkin is a biochemist; Dr. Likins is a chemist; Dr. McClure, chief of the laboratory, also is a biochemist; and Mrs. Steere is a biologist.

John D. Rust and Frederick A. Bullock, formerly with the laboratory, assisted in collecting the specimens in Montgomery County, Md. Virginia L. DuBois, with the Epidemiology and Biometry Branch of the National Institute of Dental Research, assisted in arrangements for collection of the urine specimens in Grand Rapids, Mich. Dr. Albert L. Russell, chief of that branch, made the statistical analysis of portions of the data.

Moreover, it was not determined in any of these studies how soon after beginning the regular ingestion of a fluoride water a stabilized equilibrium is attained, nor was any attempt made to investigate the rate of fluoride excretion in individuals of various ages.

The present study was undertaken, therefore, to provide the following information with respect to fluoridated drinking waters: (a) the relation between the level of fluoride in the drinking water and the concentration of fluoride in the urine, (b) the time required after fluoridation for this relation to become stabilized, and (c) the effect of the age of the individual on the time required for establishment of this equilibrium.

The advent of water fluoridation in Montgomery County, Md., in December 1951 made it possible to obtain such information. Additional, preliminary information was available from Grand Rapids, Mich., where the urinary excretion of fluoride had been under observation since the start of water fluoridation in January 1945. For comparison with the data from these two areas, the results of a survey in 1948 in Aurora, Ill., are presented. The drinking wa-

C. tarsalis and *C. quinquefasciatus* were the predominant species in all habitats associated with municipal sewage disposal (table 4). These 2 species comprised 88 percent of over 14,000 larvae collected from the 4 habitats. *A. dorsalis* and *A. nigromaculis* together comprised more than one-fourth of over 4,800 larvae taken from the sewage lagoon at Abernathy.

Summary and Conclusions

Detailed studies during 1954 in representative areas of the irrigated High Plains in Texas showed that *Culex tarsalis*, the common encephalitis mosquito, was abundant from early June through September. It ranked second in the total number of female mosquitoes taken in light traps and was the most abundant species in larval collections. In biting collections on human hosts at Plainview, *C. tarsalis* ranked second at urban sites and third at rural sites. *Culex quinquefasciatus* was abundant during the latter part of the season in both urban and rural areas. It ranked third in the urban and sixth in the rural light trap collections. Western equine encephalitis virus was isolated from 3 out of 15 pools of *C. tarsalis*, and from 1 out of 17 pools of *C. quinquefasciatus*.

Aedes nigromaculis ranked first in the total number of female mosquitoes taken in light traps. It also ranked first in the rural and third in the urban biting collections. *Aedes vexans* ranked fifth in the total number of females taken in the light traps, but it ranked first in the urban and second in the rural biting collections. The abundance and widespread distribution of *C. tarsalis*, *C. quinquefasciatus*, *A. nigromaculis*, and *A. vexans*, and the presence of encephalitis virus constitute a significant public health problem in the Texas High Plains.

Playa lakes on native grazing land accounted for approximately three-fourths of the mosquito production in the study areas. Surface pools and roadside ditches and borrow pits were also important sources of mosquitoes. Waste and residual irrigation water accounted for 87 percent of the total mosquito production at Plainview, and 45 percent at Hereford. Practically all of the remaining production was caused by surface runoff from local rains.

Throughout the High Plains area, much of

the water that collects in the playas is lost through evaporation and transpiration. This loss of water is vitally important to the economy of the region, because the underground reservoir is being lowered by pumpage for irrigation at a much greater rate than it is being replenished. Various methods of making beneficial use of the water that is now lost from the playas have been suggested, and several are being tested at the present time. These and other water conservation measures should be evaluated from agricultural and mosquito control viewpoints. In this area, as in others, such viewpoints are likely to be served by the same methods. Where mosquito production cannot be eliminated by water conservation measures, chemical control will be necessary.

Mosquito production associated with municipal sewage disposal is not as widespread as that caused by irrigation waste water and surface runoff; however, this is a special problem for which both temporary and permanent control measures are needed.

10 collections, the subjects remained in their particular group relative to age and time of day. Approximately 10 specimens, 1 from each subject, were obtained for each of the 36 age-time groups. Equal volumes from these 10 specimens were pooled to provide the sample for analysis. No consistent variations in fluoride content with the time of the day the specimen was taken were observed; therefore, only mean fluoride values for each age category are given in this report. In the 11th collection, the specimens were obtained without regard for the time of day and were pooled for each age category to furnish four samples for analysis.

In the Grand Rapids survey, spot urine specimens were obtained from male school children aged 6 through 17 years. Approximately 15 spot specimens comprised each pool, and from 1 to 4 pools were analyzed for each age group. Continuous residents furnished the specimens for the last three collection periods. This survey, which was begun before the Montgomery County survey, did not parallel it in all details.

Fluoride Concentrations in Urine

The data on urinary fluoride concentrations for the Montgomery County residents are shown in table 2. Prior to fluoridation, the fluoride content of the specimens varied from 0.2 to 0.3 p.p.m. As early as 1 week after fluoridation, it was evident that the children

were responding quite differently from the adults. At the end of 1 week, the adults' specimens contained 0.7 to 0.8 p.p.m. fluoride. At the end of 6 weeks, they contained the expected 1.0 p.p.m. fluoride (10). For these same periods, the fluoride concentration in the urine specimens from the children averaged about half these concentrations, and, although the children varied in age from 5 to 14 years, the fluoride content was essentially uniform for all. As shown by the data for succeeding sampling periods, about 3 years elapsed before the specimens of the children reached 0.9 to 1.1 p.p.m. fluoride.

In table 3, the ratio of urinary fluoride concentration to water fluoride concentration in Montgomery County for each collection period following fluoridation is shown. These ratios illustrate the particularly striking difference between the children and the adults during the first 2 years ($t=8.82$, $P < 0.01$). Equilibrium was reached by the adults after 1 week of fluoridation, whereas approximately 3 years was required for equilibrium to be reached by the children.

The data on urinary excretion of fluoride for the Grand Rapids residents are shown in table 4. The prefluoridation value of approximately 0.2 p.p.m. fluoride in the urine is consistent with the use of the original Grand Rapids water, which contained 0.1-0.2 p.p.m. fluoride. Approximately 2 months after fluoridation was started, the fluoride content of the urine had

ter in Aurora has contained approximately 1.0 p.p.m. fluoride from natural sources since 1895 (2).

Spot Specimens vs. 24-Hour Samples

The difficulties in obtaining 24-hour urine specimens in a study of this extent are obvious. Accordingly, spot specimens from a number of individuals were pooled in equal volumes to provide a sample for fluoride analysis. Early in the study, information was obtained regarding the relation of the fluoride content of spot specimens to that of the 24-hour total volume.

During a 24-hour collection period, spot specimens were taken between 9 and 12 a. m., 2 and 5 p. m., and 8 and 11 p. m., from 9 adult males who were drinking water containing 1.0 p.p.m. fluoride provided as sodium fluosilicate. These samples, as were all samples in the study, were alkalized with calcium oxide prior to evaporation and ashing and analyzed for fluoride according to standard procedures (5, 6). The results are shown in table 1.

The fluoride concentration in a single spot specimen may vary considerably from that in the 24-hour sample. However, according to the *t* test, the mean concentrations for the 3 spot specimens from the 9 men (0.9 p.p.m., 1.0 p.p.m., and 1.1 p.p.m.) did not vary significantly from the mean fluoride concentration of 0.9 p.p.m. for the 24-hour samples.

¹ Corrected for spot specimen analysis.

These results apply to exposure to 1.0 p.p.m. fluoride in the drinking water. They agree very well with the data obtained by Largent and Ferneau for other levels of fluoride (7). It appears, therefore, that the fluoride concentration of pooled urine specimens for a group of individuals reflects reasonably well the average fluoride concentration in 24-hour specimens.

Fluoridation of the Drinking Water

Beginning December 28, 1951, the drinking water of Montgomery County, Md., has been fluoridated to approximately 1.0 p.p.m. fluoride by the addition of sodium fluosilicate. The water supplying this area is obtained from the northwest branch of the Anacostia River (8). Water samples taken at widely scattered points in the study area for 10-day periods at the time of the urine collections showed approximately 1.0 p.p.m. fluoride after an initial adjustment period lasting 2 to 4 weeks.

The communal water of Grand Rapids, Mich., which is obtained from Lake Michigan, has been fluoridated for more than 10 years with sodium fluoride. The fluoride content has been maintained at a relatively constant level of 1.0-1.1 p.p.m. (9).

Sampling Procedures

The subjects studied in Montgomery County were male school children and male adults who had had no exposure to a fluoride-containing drinking water before the start of fluoridation and who were in continuous residence thereafter. Nine age categories, as shown in table 2, were represented. At the start of the study, the subjects in each age category were divided into four groups according to the time of day the specimen was obtained. The same subjects were followed throughout the course of the study. For the age category 5-14 years, the 4 collection periods were 8:30 to 10:30 a. m.; 10:30 a. m. to 1 p. m.; 1 to 2 p. m.; and 2 to 3 p. m. For the age categories 30-34 and 35-39, the first 2 collection periods were the same as for the younger age groups, and the second 2 were: 1 to 3 p. m. and 3 to 5 p. m.

Eleven collections of urine were made during a period of about 3½ years. For the first

is clearly shown by the data for the adults in Montgomery County. As early as 1 week after fluoridation, the fluoride concentration of the urine was approximately that of the drinking water.

There is some indication that the period of adjustment was somewhat shorter for the children of Montgomery County than for those of Grand Rapids. The suggested difference in the two areas cannot reasonably be ascribed to a difference in the fluoridating agents, as it has been shown in studies with the white rat that sodium fluoride and sodium fluosilicate have similar metabolic effects (13, 14). It is possible that the variation in sampling procedures was at least partly responsible for the seeming difference. It is also possible that the difference was due partly to the quantity of water ingested. Water consumption, and thus total fluoride ingested, may have been higher in Montgomery County, owing to the consistently higher mean monthly temperature in that area than in Grand Rapids. The temperature difference averages about 10 degrees throughout the year, according to information from the United States Weather Bureau. It is significant that in both Montgomery County and Grand Rapids the children reached the same state of apparently stabilized equilibrium between urinary fluoride concentration and water fluoride concentration as the adults in Montgomery County, even though they required a somewhat longer period of time.

Speculation as to the reasons for the apparently different response of the children and the adults must turn largely to the possibility of basic differences in fluoride metabolism reflected in the skeletal retention of fluoride. The rapid attainment of equilibrium in adults suggests certain limitations in the capacity of mature bone to deposit fluoride. In this connection it may be noted that the mature rat, without prior exposure to fluoride, stored considerably less fluoride in bones and teeth than did the young growing rat, although they ingested equal amounts of fluoride in their drinking water (15). Decreasing amounts of fluoride were stored by rats as the rate of growth diminished, and at maturity a relatively constant level of skeletal fluoride was attained. On the basis of these experimental data, it would seem reason-

able for adults to excrete more fluoride than children and hence reach an apparent equilibrium between the concentration of urinary fluoride and water fluoride at an earlier date. The data of the present study thus lend support to the proposition that the retention of fluoride by bone is influenced by its state of maturity.

The length of time required for the children to reach a relatively constant concentration of urinary fluoride suggests some elevation in the fluoride deposited in the skeletal tissues during this adjustment period. However, this increase in retained fluoride would seem to be very small. The urine during the adjustment period contained 0.5-0.6 p.p.m. fluoride, providing for the elimination of substantial quantities of the waterborne fluoride. It has been shown that no adverse effects on the growth and development of the carpal bones accompany the continuous use of natural fluoride drinking water containing approximately 3.0 p.p.m. or more of fluoride (16). In addition, examinations of children after 10 years of use of a water supply containing 1.2 p.p.m. fluoride added as sodium fluoride failed to reveal anything unusual with respect to the blood, urine, height, or weight; and roentgenographic studies on the hand, wrist, knees, and lumbar spine of these children showed normal development (17). These observations support the conclusion that whatever this increase in the retention of skeletal fluoride by these younger age groups may have been, it was not a health hazard.

Summary

The concentration of fluoride in the urine was determined in individuals of different ages who were drinking water fluoridated to approximately 1.0 p.p.m. fluoride with sodium fluosilicate (Montgomery County, Md.) or with sodium fluoride (Grand Rapids, Mich.).

In adults (Montgomery County), the water fluoride and urinary fluoride concentrations became approximately equal within 1 week after the introduction of the fluoridated water. In school children aged 5 through 14 years (Montgomery County) and 6 through 17 years (Grand Rapids), a considerably longer period of time (approximately 3 and 5 years respectively) elapsed before the concentration of

Table 3. Ratio of urinary fluoride to water fluoride, Montgomery County, Md.

Time after fluoridation	Fluoride in water at tap (p.p.m.)	Urinary fluoride/water fluoride ratio, by age group	
		5-14	30-39
1 week-----	0.7	0.4	1.1
2 weeks-----	.8	.6	1.1
4 weeks-----	1.0	.5	.9
6 weeks-----	.9	.6	1.1

2 years, 48 weeks-----	1.2	.8	.9
3 years, 24 weeks-----	.9	1.0	1.1

increased to 0.6 p.p.m. Approximately 5 years after the start of fluoridation, some of the school pupils were excreting 1.0 p.p.m. fluoride (ages 6, 7, and 17). In the final three collections in Grand Rapids (1952, 1954, and 1955), the excretion of fluoride averaged 1.0 p.p.m. for all age groups. The ratios of urinary fluoride to water fluoride would be the same as the mean urinary fluoride values, since the fluoride content of the water has been kept at a practically constant level of 1 p.p.m.

The 1948 survey in Aurora, Ill., provides the most recent data for that city. The fluoride content of urine specimens from boys aged 8 through 17 years varied from 0.8 to 1.0 p.p.m. and averaged 0.9 p.p.m. All age groups showed approximately the same fluoride concentrations. It remains speculative as to when these subjects arrived at this apparently stabilized relation

between fluoride in the urine and fluoride occurring naturally in the drinking water. Similar data pertaining to the urinary excretion of fluoride in Aurora residents are presented elsewhere (10).

Discussion

Efficient elimination of fluoride by urinary excretion has been demonstrated in several clinical and experimental studies (1, 3, 4, 10-12), and is now considered one of the main deterrents to the accumulation of a toxic amount of fluoride in the body tissues. It has been shown also that fluoride is eliminated with equal facility by persons drinking naturally fluoridated water (1, 10-12) and by those drinking artificially fluoridated water (3, 4).

The surveys in Montgomery County and Grand Rapids demonstrated a similar high level of efficiency in the urinary elimination of fluoride added to the drinking water as sodium fluosilicate or sodium fluoride. The findings confirm the results of previous studies, which showed that approximately 1.0 p.p.m. fluoride is found in the urine when fluoride is ingested in drinking water containing 1.0 p.p.m. from natural sources (10) or added as sodium fluoride (3, 4). The findings are regarded as evidence that no hazard of cumulative toxic fluorosis is associated with the use of fluoridated water containing 1.0 p.p.m. fluoride.

An important consideration pertaining to water fluoridation is the time required for a stabilized equilibrium between water fluoride and urinary fluoride to be reached. That the period of adjustment can be remarkably short

¹ Fluoridation was begun Jan. 25, 1945.

Last year's outbreaks of salmonellosis in Philadelphia reemphasize the need for vigilant health department supervision of food processing and distribution practices.

Smoked Fish as a Vehicle of Salmonellosis

By I. OLITZKY, Ph.D., A. M. PERRI, M.D., M.P.H.,
M. A. SHIFFMAN, D.V.M., M.P.H., and M. WERRIN, V.M.D.

DURING the 1955 Memorial Day weekend, May 28-30, there occurred in Philadelphia three outbreaks of gastroenteritis in which smoked fish was the vehicle for the transmission of *Salmonella* organisms. The events preceding and including the outbreaks have the elements of a classic picture of *Salmonella* food infection.

To those concerned with the public health aspects of food production, distribution, and consumption, it has long been apparent that delicatessen foods are always potential vehicles for bacterial intoxications and infections. The factors supporting this potential are: The foods are generally consumed without further cooking, and some processors and many distributors and consumers disregard their perishable nature.

More than a decade ago, Kleeman, Frant, and Abrahamson (1) reported in detail two outbreaks in New York City of food poison-

ing associated with smoked fish. These events led to changes in the New York City Code with respect to the production and distribution of smoked fish products (2). One of the outbreaks affected 47 persons in 18 families and resulted in 2 deaths. The investigation of the food plant where it occurred revealed the following epidemiological chain, quite similar to that observed in Philadelphia.

Fish in the plant were contaminated with *Salmonella typhimurium*, apparently conveyed by sewage in the washing, soaking, and brining vats.

The process of salting and smoking the fish was not drastic enough to destroy the pathogens.

The lack of refrigeration throughout the entire food distribution system provided almost ideal temperatures for bacterial growth.

Smoked Fish

The annual processing and consumption of smoked fish in the United States—of kippered salmon, smoked sablefish, smoked whitefish, smoked carp, lox, and similar products—amount to millions of pounds. Even with this volume, the methods of processing have not been touched by technological advances, partly because, perhaps, many of the processing plants are small businesses, family-owned.

All four authors are associated with the Philadelphia Department of Public Health, Dr. Olitzky as principal bacteriologist and assistant chief, public health laboratory section, and his colleagues as chiefs of their respective sections: Dr. Perri, communicable disease control; Dr. Shiffman, milk and food sanitation; and Dr. Werrin, veterinary public health.

fluoride in the urine reached that in the drinking water.

The difference in the response of adults and children during the initial period of exposure to a fluoridated drinking water suggests that the maturity of human skeletal tissue influences its capacity to retain fluoride.

The results of the study do not suggest any essential difference in urinary elimination of fluoride ingested in naturally fluoridated drinking water and the elimination of fluoride ingested in drinking water fluoridated with either sodium fluoride or sodium fluosilicate.

The findings are regarded as evidence that no hazard of cumulative toxic fluorosis is associated with the use of a drinking water fluoridated to contain 1 p.p.m. fluoride.

eggs, blintzes, sour cream, noodle pudding, and ginger ale. The smoked fish products were eaten by 13 people. Eleven of them became ill.

The case histories revealed that the incubation periods ranged from 9 hours to 89 hours with a mean of 26 hours.

Case 10 became ill on May 30 at 3 a. m. and had severe abdominal cramps, vomiting, and diarrhea. Case 12 became ill at 6 a. m. and had similar symptoms and chills as well. Case 13, wife of case 12, ate some of the food but was not

ill. Case 11, husband of case 10, also remained asymptomatic after partaking of the food.

Eight persons, cases 14-21, became ill 24 hours after the supper. All 8 had symptoms of severe diarrhea and abdominal pain, and 1, the hostess (case 21), was hospitalized. Case 22 became ill 89 hours after the meal. He had chills, slight fever, and abdominal pain.

A stool culture taken from the hostess on June 14 was positive for *S. newport*. The organism was isolated also from the feces of 6 others and from 1 of the 2 asymptomatic individuals.

Food Processors and Retail Outlets

The health department started its sanitation investigation after receiving routine notification of the outbreaks in which smoked fish was the apparent vehicle. Calls at the affected households established where the fish products had been bought in each instance.

The kippered salmon eaten by the S family came from the J delicatessen, where sanitary conditions were found to be relatively good. The variety of smoked fish eaten by the W family was purchased at the G delicatessen, which had a refrigerated showcase in need of cleaning. The smoked fish products, however, were not stored in the showcase of the G delicatessen but were kept on top of the counter. The internal temperature of smoked whitefish tested at the store by our sanitarian was found to be 70° F. Presumably, the fish would stay on the counter until sold or otherwise disposed of and would remain at room temperature all the time.

The smoked whitefish eaten at the buffet supper had been purchased at the F delicatessen. There, too, the smoked fish were kept on a counter, fully exposed and unrefrigerated. The internal temperature of a sample smoked fish was 63° F. The fish were kept out all day at room temperature, and at closing time they were placed in a walk-in refrigerator, where the temperature was 36° F. There was some evidence of rodents in the storeroom although general sanitary conditions in the delicatessen were good.

Smoked fish are transported from the processor to the delicatessen in a refrigerated truck

In the past, smoking of foodstuffs was essentially a means of preservation. With modern methods of preservation based on low-temperature storage, there is less need for a heavy smoke. In effect, the light smokes now used are primarily for flavoring the fish.

There are many variations in the smoking process for different types of fish and other food products. One variation applies to the preparation of kippered salmon, one of the products implicated in the Philadelphia outbreaks.

Salmon are usually received in a frozen state and are thawed in tanks or in running water. After thawing, each fish is split and cut into approximately 1-pound pieces, which are then brined from one-half to 2½ hours in a salt solution having 90° to 95° salometer reading. The fish, after being dyed a uniform color with certified dye, are placed on small hooks on wire-bottomed trays. The fish are allowed to drain in the smokehouse racks for several hours and then are heat dried at 80° F. for 8 to 12 hours. To finish off the kippering process, the fire is built up with sawdust and wood chips or shavings to give a hot smoke for about 1 hour at 175° to 180° F. The kippered salmon are cooled by means of circulating air, and then they are wrapped by hand.

There is no question that fish processed in the manner described are perishable products, to be kept under constant refrigeration. The wrappers on the kippered salmon in the Philadelphia outbreaks were clearly printed with a notation that the product was perishable and was to be refrigerated, but we found that these instructions were generally disregarded by the retailers. We found also that whitefish and lox are distributed unwrapped.

The Philadelphia Outbreaks

The first outbreak of salmonellosis in Philadelphia, designated the W family outbreak, was reported as food poisoning to the communicable disease control section of the City of Philadelphia Department of Health on June 2, 1955. The mother in the family and her two children had symptoms of fever, abdominal pain and diarrhea at 6 a. m., Saturday, May 29. The family had eaten smoked whitefish,

kippered salmon, bagels, and cream cheese at 6 p. m. the evening before, May 28. The father ate the food but did not become ill.

The two children were hospitalized for treatment by their family physician. Stool cultures performed at the hospital were reported as negative for enteric pathogens, but cultures performed at the public health laboratory on July 2 were positive for *Salmonella newport*.

On June 3 a sanitarian from the health department milk and food section visited the W family. Fortunately, some of the fish was still in the refrigerator, uneaten, and he took it to the laboratory for analysis. The finding of large numbers of *Salmonella* organisms in the fish alerted the department to expect reports of other cases of food poisoning since large quantities of smoked fish products are consumed on weekends.

The pertinent facts of the W family cases and of the other 2 Philadelphia outbreaks are given in table 1. The children and mother in the W family are listed here as cases 1, 2, and 3, and the father, who was not ill, as case 4.

The S family outbreak was the next. The mother, father, and 2 children in the family ate smoked whitefish at 10 a. m. on May 29. The 2-year-old child (case 5) became ill 47 hours after the meal and was treated at a local hospital where her illness was diagnosed as salmonellosis.

The other members of the family (cases 6, 7, and 8), although asymptomatic, were found on routine culturing to be excreting *S. newport*. The grandmother (case 9) of the children took care of the sick child, and, although she did not partake of the food, she became ill with fever and diarrhea on June 10. Cultures taken from her on June 16 were found to be positive for *S. newport*.

The third and largest outbreak occurred as the result of a buffet supper, attended by some 30 persons, on May 29 at 6 p. m. Immediate steps were taken June 5 to study the outbreak after an alert practitioner telephoned the department that he was treating four patients who had symptoms of food poisoning.

Most of our information about the supper was obtained at the home where it was served. The foods consumed were smoked whitefish, lox, tunafish, salmon salad, potato salad, hard-boiled

Table 4. Bacteriological findings in smoked fish from W family outbreak ¹

Bacteria	Kipperd salmon	Lox	Smoked whitefish
Bacterial count (plate) per gram	1.3×10^9	20×10^8	180×10^8
Staphylococci (coagulase-positive) per gram	26×10^8	6.5×10^8	6×10^8
Enterococci (MPN/gm.)	11×10^8	11×10^8	11×10^8

Source of *Salmonella* Organisms

At the same time plants A and B were being subjected to sanitary inspection, a medical officer from the communicable disease control section of the health department visited both processing plants and arranged to collect fecal samples from all employees. He examined approximately 70 employees and found one, an employee in plant A, to be excreting *S. newport*. Finding of the salmonella carrier was reported by the laboratory on June 13, 11 days after the first cases were reported to the health department.

The carrier (case 23), a woman aged 30, gave a history of illness beginning May 6, 1955, 3 weeks before the outbreaks. She had fever, abdominal pain, and vomiting, and was treated in the outpatient department of a local hospital. The hospital, however, made no effort to take cultures or to diagnose the illness of the patient, who continued to work at the processing plant until she was discovered to be a carrier. In this particular instance, the failure of the hospital to take a culture from a patient with an obvious gastrointestinal complaint had serious consequences.

Upon questioning, the owners of plant A denied that the carrier handled, wrapped, or packed smoked fish, but the carrier, when questioned, stated that she wrapped and packed smoked fish 7 out of 8 hours a day.

Discussion and Conclusions

Improved bacteriological techniques and more conscientious reporting of cases by hospitals and practitioners than in the recent past

are the main factors behind the apparent increase in outbreaks of salmonellosis in Philadelphia as well as throughout the rest of the country. Salmonellosis was made reportable in Philadelphia in 1944 and in the State of Pennsylvania in 1952. Typhoid and paratyphoid A and B infections have been reportable to the Pennsylvania State Health Department since 1861.

To this day, however, many outbreaks of salmonellosis in family groups are not reported. Because of the long incubation period perhaps, the family gives no thought to the probability that the illness may be due to a food infection. Many persons have been made conscious, and erroneously so, of virus infections. As a result, illness caused by *Salmonella*, which has a short course, may be mistaken for the so-called epidemic nausea, diarrhea, and vomiting of virus origin. Because of failure to perform laboratory studies, many cases of salmonellosis may go undiagnosed even though the sick are treated by physicians. There is no question, however, that practicing physicians have become increasingly aware that gastroenteritis may be due to *Salmonella* infections rather than to other causes.

Epidemiological investigations of food poisoning or food infection outbreaks often are frustrating experiences. Although the elements in the chain of events can be visualized and theorized, it is impossible in many instances to obtain solid laboratory proof to support the theory. Frequently, the suspected food is not available for analysis, or the source of the etiological agent, the carrier, cannot be found.

We were fortunate that the suspect food from one of the outbreaks was available to us and that analysis revealed the causative organism. Thanks to the cooperation of many physicians treating the victims, fecal specimens could be examined. We were able to find a carrier in one of the food-processing plants. The lack of washroom facilities in the plant was conducive to the establishment of the anal-oral route of infection. There was almost complete lack of refrigeration of the fish products in the local retail outlets. Thus, all the elements necessary to close the epidemiological investigation were present.

where the temperature is maintained at about 40° F. One truck from processing plant A served the area containing the three retail outlets investigated. Since the sale of smoked fish products is heavy on weekends, and delivery of the fish usually precedes the weekend, it is quite possible that orders for all three stores came from the same shipment, but we could not ascertain that as a fact.

The processors said that they instruct the delicatessens about the need for refrigerating smoked fish because of its perishability. Nevertheless, many of the delicatessens fail to keep the products under refrigeration, and, since the stores may be open until the early hours of the morning, the fish are likely to remain at room temperature for a long time.

The Processing Plants

Each of the 3 retail outlets was served by the 2 food processors in Philadelphia who prepare smoked fish of the variety considered here. The A plant is located near the dock area on the Delaware River, where the buildings are old and where the original city was founded. Some attempts to improve the old building occupied by the A plant had been made. The floor was in fairly good condition in the room where the fish are thawed, washed, cut, brined, and wrapped. The walls had been recently tiled, and stainless steel tables had been provided for cleaning the fish and for the final wrapping. Housekeeping was poor. Boxes, odd containers, and miscellaneous objects and racks had accumulated on the floor and under tables. The windows were not effectively screened, and a dead mouse was found in the storeroom.

Most germane to the outbreaks was the condition of the toilet rooms and the handwashing facilities. The toilet rooms used by employees in the processing and wrapping operations were remote. The water closets were barely operative. The basin for handwashing was not provided with hot water. The cold water barely flowed. No sanitary towels or soap were available. The entire toilet premises were encrusted with a long-standing accumulation of dirt.

Conditions were generally good in plant B, which is housed in a relatively modern building.

Even there, however, a handwashing basin adjacent to one toilet room did not have flowing water because of inadequate supply lines. When large quantities of water were used elsewhere in the plant, water would not run out of the faucets in the wash basins.

During the first inspection of processing plant A, samples of water from the soaking tanks, samples of brine from the salting tanks, and samples of freshly processed fish ready to be sent to the retail outlets were collected and taken to the laboratory for bacteriological analysis, shown in tables 2 and 3. The results of the analysis of water and brine from the plant are in line with the insanitary conditions there.

Table 2. Bacteriological findings in water and brine from plant A

Bacteria	Water		Brine
	Tank 1 ¹	Tank 2 ²	
Coliforms (MPN/100 ml.)	9, 300	2, 100	110, 000
<i>Escherichia coli</i> (MPN/100 ml.)	700	400	15, 000
Enterococci (MPN/100 ml.)	930	90	230
Bacterial count (plate) per ml.	14, 000	1, 500	16, 000

¹ Tank used to wash fish. ² Tank used to soak and store salmon filets.

Table 3. Bacteriological findings in smoked fish from plant A

Bacteria	Kippered salmon	Smoked whitefish
Bacterial count (plate) per gram ¹	900	1, 580, 000
Staphylococci (coagulase-positive) per gram ²	0	31, 000
Enterococci (MPN/gm.) ³	0	0
Salmonellae	0	0

¹ Plate count agar (Difco). ² Salt agar similar to mannitol salt agar (Difco). ³ SF medium (Difco).

It is of interest to compare the bacteriological findings of the fish samples from the A plant with the findings for the fish obtained from the W household, in tables 3 and 4. It is readily apparent, particularly with respect to the kippered salmon, that the bacterial population increased tremendously by the time the fish reached the consumer.

and 4 children were made ill directly by consumption of the food, and 1 adult was made ill through secondary infection. The chain of events leading up to these outbreaks was:

The failure of a hospital clinic to culture a stool specimen from a patient with gastrointestinal symptoms.

The failure of a food processing plant to provide adequate sanitary facilities for its personnel.

The failure of retail outlets to refrigerate a highly perishable food item.

Surgeon General Scheele Resigns

Effective August 2, 1956, Dr. Leonard A. Scheele resigned as Surgeon General of the Public Health Service to become president of Warner-Chilcott Laboratories.

Marion B. Folsom, Secretary of Health, Education, and Welfare, commented that Dr. Scheele's "imagination, skill, and resourcefulness" have played "a particularly significant role in the development of many new and expanded programs which have

notably advanced the health of the American people."

Commissioned in the Regular Corps of the Public Health Service in 1934, Dr. Scheele gave 22 productive years to Government service, including 4 years in the armed services. He was appointed director of the National Cancer Institute in 1947 and was appointed Surgeon General in 1948.

Salmonella newport

S. newport is the second most prevalent *Salmonella* type found in food infection outbreaks. *S. typhimurium* heads the list. *S. newport* is widely distributed in the United States. In studying 310 cultures of *S. newport* during the period 1934-47, Edwards, Bruner, and Moran (3) found that 220 cultures were isolated from cases of gastroenteritis. A Public Health Service report (4) on food poisoning outbreaks in 1954 indicates that *S. newport* was often implicated in the 1,090 cases representing 22 outbreaks associated with food during that year.

S. newport itself would seem to be one of the more potent inciters of gastroenteritis in the *Salmonella* group. The carefully controlled feeding experiments reported by McCullough and Eisele (5) revealed that, of the *Salmonella* types used, *S. bareilly* and *S. newport* could produce illness with small dosage levels. One of the subjects became ill after ingesting 152,000 *S. newport* organisms. Although we do not know the number of organisms introduced to foods by the feces-contaminated hands of carriers, it is readily apparent in our study that the lack of refrigeration in the retail outlets did result in more than enough organisms to produce symptoms of gastroenteritis.

Salmonella Carriers

A convalescent carrier was the source of the etiological agent in the Philadelphia outbreaks. We do not know at this time what percentage, if any, of the others in the outbreaks will become chronic carriers.

The chronic carrier state in humans is rarely observed with salmonellae other than *Salmonella typhi*. Recent experiences indicate that the convalescent carrier state may last longer than was generally assumed. Every person reported as a case in the outbreaks and as having had a positive culture is being considered as a convalescent carrier, and cultures are taken as follows:

The first, second, and third stool cultures are taken at least 5 days apart, beginning after the 14th day of the last dose of any antibiotic or chemotherapeutic agent. If the first 3 cultures are negative, the fourth culture will be taken 1 month after the third culture. If any

of the first 3 cultures are found to be positive, the person will be referred for further treatment. The fifth and sixth cultures will be taken a month apart, and the seventh culture will be taken at the end of the sixth month—again provided that the cultures are negative. If cultures taken from anyone from the fourth month on are positive, then the individual will be considered a chronic carrier of salmonellae and will be placed on a list of chronic carriers.

The results of the followup stool cultures on the cases to date of this report are shown in the last column in table 1. *S. newport* was found in the feces of some of the victims 2 to 3½ months after the outbreaks.

Lessons To Be Learned

Although the cases we report here are new, the lessons to be learned are old, but they are repeated again for the educational value attributed to repetition. We are aware that even the most rigid food-handler examination program is not perfect in detecting carriers of bacterial enteric pathogens. It is possible for a food handler to become a carrier soon after the annual or semi-annual fecal examination. Thus, in addition to legislation, the importance of educating management and workers in the food industry to the prime requirement of providing and using adequate washroom facilities is paramount.

The failure of retail outlets to refrigerate items that are highly perishable and that are consumed without further cooking cannot be condoned. It is quite apparent that health departments must exercise constant surveillance of local food processors, distributors, and retailers in order to enforce the refrigeration requirements of perishable foods.

The public must be educated to the fact that light smokes and salts used in present day smoked fish processing are not in themselves sufficient for the safe preservation of fish products.

Summary

We have described three outbreaks in Philadelphia in 1955 of salmonellosis in which smoked fish products served as vehicle for the transmission of *Salmonella newport* from carrier to susceptible consumer. Eleven adults

home, refrigeration, and the health of the family as a whole and its influence on the new baby.

2. *The New Baby Comes Home*

With the use of a doll model, the physician and a public health nurse discussed and demonstrated a typical layette. The physician then pointed out the physical characteristics of a newborn and of a 6-week-old baby and discussed the kind of behavior to be expected through the first 6 weeks of life.

3. *Baby Gets a Bath*

The physician discussed the skin and its care. The nurse then bathed a 2-month-old baby. In preparation for this program, the nurse bathed the infant several times in his home so that she and the baby would be accustomed to each other.

4. *Feeding and Formula Making*

Breast and bottle feeding and the need for vitamin supplements were discussed by the physician. A public health nurse then demonstrated the terminal heating method of formula preparation.

5. *Mother's Night Out*

The physician discussed and demonstrated the physical and behavioral characteristics of a 3-month-old child. Then, while the physician spoke of the "introduction of solid foods," the mother demonstrated how to feed a baby with a spoon. The second half of the program dealt with the mother's need for recreation, how to choose a baby sitter, and what the baby sitter should know.

6. *Baby Visits His Doctor*

This program opened with the physician telling of the need for regular medical supervision of the well infant. A pediatrician, a mother, and her 4-month-old baby then demonstrated a typical well-baby visit to the doctor. Emphasis was placed on the importance of regular health supervision, immunization, anticipatory guidance, and a permissive atmosphere in which the mother feels free to raise questions and discuss her problems. The mother had been attending the child health conference in which

the pediatrician worked. Therefore, she was quite at ease before the cameras and brought up for discussion traditional beliefs in child care held by older mothers in her subculture. Also, the second diphtheria-pertussis-tetanus inoculation was given on the program.

7. *Baby Graduates to the High Chair*

The physician opened the program with a discussion of the physical, motor, and emotional characteristics of the average 6-month-old infant, demonstrating her points with two 6-month-old babies. One child was then placed in a high chair and was offered milk from a glass while the physician talked about weaning, learning to drink from a cup or glass, teething, and thumbsucking. Later, the physician discussed and demonstrated, by offering toys to the babies, safe and suitable toys.

8. *Baby Starts to Crawl*

This program began with one 9-month-old baby seated in a playpen while the physician talked about the characteristics of this age group. Fraternal twins were then introduced, and the physician and mother discussed the special problems of a mother with twins. The three babies were permitted to demonstrate their own modes of crawling in free play on the nursery floor, while the physician suggested how the home can be made safe for the creeping baby.

9. *Baby's First Step*

Using three 1-year-old babies as models, the physician demonstrated and discussed the physical characteristics and motor abilities of that age group, with special emphasis on normal variations, proper weight-bearing on the feet, and the importance of well-fitted shoes. The children were then permitted to play on the nursery set as the physician talked about the changes in eating habits and other behavior patterns to be expected in the age group.

10. *Toddlers*

While the physician talked about growth and development in children between the first and third years, three children, 2-3 years old, were permitted free play on the set. Mothers intervened only to settle altercations over possession

The Use of a Series of TV Programs to Educate Parents in Child Care

By ANNE B. WAGNER, M.D., M.P.H., and MARY ELLEN PATNO, Ph.D.

SOON after the establishment in Pittsburgh, Pa., of the country's first community sponsored educational television station, WQED, its management requested the Pittsburgh Department of Public Health to cooperate in the presentation of a series of programs on child care. This article describes the content of the series and the results of a survey which was conducted among mothers with young children.

The series was entitled "At Home With Your Child." It included 13 half-hour programs, presented weekly during the first 3 months of 1955. The programs consisted of an exposition of normal physical and emotional growth from birth through the fifth year of life. More fully stated, each program attempted to describe and demonstrate how normal babies and children look and act at each key stage of development, what their needs are, and ways of meeting these needs.

In all but three of the programs, infants and

young children were used on the set to illustrate points of discussion. Children who participated were selected with a view to demonstrating the wide variation in size and motor abilities at each age level. The youngest infants were completely undressed in order to demonstrate physical appearance. Older babies, up to the age of 2 years, were stripped except for diapers. Children beyond 2 years of age were dressed in sunsuits because their emerging sense of modesty might otherwise have provoked unnatural behavior.

None of the subjects displayed uncontrollable crying or other refractory behavior which would have necessitated their removal from the studio. Fears that the lights and cameras might produce apprehension and stilted reactions proved groundless. After a cursory inspection of the studio and cameras, the youngsters devoted themselves to playing with the toys provided, and none of the subjects, from the tiniest, 10 days of age, through the 6-year-olds, paid the least attention to the lights.

The following material outlines the program titles, the various casts, and the material covered. The physician who served as narrator was the only person who appeared on every program.

1. *Preparing the Home for the Baby*

The physician and a public health nurse described, and demonstrated where possible, the nursery and its furnishings, heating in the

Dr. Wagner is chief of the maternal and child health division and Dr. Patno is chief of the office of biostatistics of the Department of Public Health, Pittsburgh, Pa. Both also are lecturers at the Graduate School of Public Health, University of Pittsburgh.

Kinescopes of the programs discussed in the article are available from the National Educational Television Center, Ann Arbor, Mich.

home, refrigeration, and the health of the family as a whole and its influence on the new baby.

2. *The New Baby Comes Home*

With the use of a doll model, the physician and a public health nurse discussed and demonstrated a typical layette. The physician then pointed out the physical characteristics of a newborn and of a 6-week-old baby and discussed the kind of behavior to be expected through the first 6 weeks of life.

3. *Baby Gets a Bath*

The physician discussed the skin and its care. The nurse then bathed a 2-month-old baby. In preparation for this program, the nurse bathed the infant several times in his home so that she and the baby would be accustomed to each other.

4. *Feeding and Formula Making*

Breast and bottle feeding and the need for vitamin supplements were discussed by the physician. A public health nurse then demonstrated the terminal heating method of formula preparation.

5. *Mother's Night Out*

The physician discussed and demonstrated the physical and behavioral characteristics of a 3-month-old child. Then, while the physician spoke of the "introduction of solid foods," the mother demonstrated how to feed a baby with a spoon. The second half of the program dealt with the mother's need for recreation, how to choose a baby sitter, and what the baby sitter should know.

6. *Baby Visits His Doctor*

This program opened with the physician telling of the need for regular medical supervision of the well infant. A pediatrician, a mother, and her 4-month-old baby then demonstrated a typical well-baby visit to the doctor. Emphasis was placed on the importance of regular health supervision, immunization, anticipatory guidance, and a permissive atmosphere in which the mother feels free to raise questions and discuss her problems. The mother had been attending the child health conference in which

the pediatrician worked. Therefore, she was quite at ease before the cameras and brought up for discussion traditional beliefs in child care held by older mothers in her subculture. Also, the second diphtheria-pertussis-tetanus inoculation was given on the program.

7. *Baby Graduates to the High Chair*

The physician opened the program with a discussion of the physical, motor, and emotional characteristics of the average 6-month-old infant, demonstrating her points with two 6-month-old babies. One child was then placed in a high chair and was offered milk from a glass while the physician talked about weaning, learning to drink from a cup or glass, teething, and thumbsucking. Later, the physician discussed and demonstrated, by offering toys to the babies, safe and suitable toys.

8. *Baby Starts to Crawl*

This program began with one 9-month-old baby seated in a playpen while the physician talked about the characteristics of this age group. Fraternal twins were then introduced, and the physician and mother discussed the special problems of a mother with twins. The three babies were permitted to demonstrate their own modes of crawling in free play on the nursery floor, while the physician suggested how the home can be made safe for the creeping baby.

9. *Baby's First Step*

Using three 1-year-old babies as models, the physician demonstrated and discussed the physical characteristics and motor abilities of that age group, with special emphasis on normal variations, proper weight-bearing on the feet, and the importance of well-fitted shoes. The children were then permitted to play on the nursery set as the physician talked about the changes in eating habits and other behavior patterns to be expected in the age group.

10. *Toddlers*

While the physician talked about growth and development in children between the first and third years, three children, 2-3 years old, were permitted free play on the set. Mothers intervened only to settle altercations over possession

of a toy. Midway in the program the children were seated at a small table and served fruit juice and crackers, while the physician demonstrated and discussed development of handedness and coordination, parallel play, and vocabulary development. The children returned to their play activities and the physician concluded with a discussion of toilet training.

11. *Community Help for Families*

The physician interviewed representatives of a public health nursing agency, of a family and children's social service agency, and of the local chapter of the American Red Cross to bring out what services each organization offered and how requests for service are made. Since this program was not considered germane to a growth and development series, it was omitted from a subsequent series.

12. *Playmates*

Three children, aged 4-5, were permitted to examine play materials provided on the set while the physician discussed physical and emotional characteristics at this age. A nursery-school teacher then led the children in a demonstration of cooperative play. During the latter part of the program, the physician talked about the control of communicable disease in the preschool child.

13. *Getting the Child Ready for School*

This final program opened with the physician pointing out the importance of careful physical evaluation of the child about to enter school.

Using two 6-year-old children as models, the physician demonstrated a vision screening test for a child of this age and the audiologist demonstrated use of the pure-tone audiometer in a screening test for hearing. The audio-engineer put on the air notes of approximately the same frequencies used in the test. The program ended with a discussion by the physician of emotional preparation of the child for school and the value of a preenrollment visit to school.

Since "At Home With Your Child" was the first program of its kind in Pittsburgh, both of its sponsors were interested in assessing the size and reactions of the audience. Both organizations preferred a survey which represented all mothers of preschool children in the Pittsburgh metropolitan area. This was not feasible. It was possible, however, to carry out a mail survey limited to recent mothers in the city of Pittsburgh.

The names and addresses of women who were queried were obtained from a sample of the live-birth certificates for the 12 months preceding the close of the series. The sample was obtained by first selecting all certificates with file numbers ending in the digits 2 or 7. Certificates for extramarital children and those who died in infancy were then excluded and questionnaires were sent by mail to the mothers of the remainder.

Followup of nonrespondents consisted of a reminder which was sent 7 to 10 days after the original questionnaire, described below, and a second questionnaire which was mailed 2 to 3 weeks after the original. Further followup by mail, the only type of followup feasible, was

not attempted for two reasons. First, there was a 70-percent response which was considered sufficient to satisfy purposes of the survey. Second, it was felt that further mail inquiry might result in criticism of the health department or the television station.

The questionnaire asked whether the family owned a television set, whether the mother saw any of the programs, and, if so, which of the programs she found helpful. All other data, such as those concerning race of mother, age of mother, size of family, and place of residence, were obtained from the birth certificate. In this report only the race, age of mother, and size of family are considered. The age groups used are: under 20 years, 20-29 years, and 30 and over. Family sizes have been described according to the number of children, namely: 1 child, 2 or 3 children, 4 or more children.

The sample included 2,476 mothers. Of these, 141 or 5.7 percent could not be reached through the mail. In these cases, the original questionnaire was returned by the post office with the notation that the person was not known at the address or that the person had moved and had left no forwarding address.

As in most surveys of this kind, the relative number of persons not reached through the mail was greater for the nonwhite. While 4.8 percent of the letters to white mothers were returned by the post office, 10.1 percent of the letters to nonwhite mothers were not delivered. The number of questionnaires not delivered also varied with the age of the mother and the size of the family. For example, the proportion of white mothers not reached de-

creased as the age of the mother increased or as the size of the family increased. In other words, within a given age group, the proportion of questionnaires delivered increased as there were more children in the family; and, for given family sizes, the proportion increased as the age of the mother increased. Among the nonwhite mothers, a slightly different pattern was observed. As with white mothers, the number not reached by mail decreased as the age of the mother increased; but, unlike the white, the number of nonwhite mothers who did not receive the questionnaire increased as the size of family increased.

Women who presumably received the questionnaire numbered 2,335. Of these, 1,646 or slightly more than 70 percent responded. White mothers responded better than nonwhite mothers, older mothers better than young mothers, and women with 2 or 3 children better than those with only 1 child or with 4 or more children (table 1). Since only 20 percent of the respondents reported they had watched the series, the response was remarkably high. Three factors may have contributed to the good response. First, the Pittsburgh area has not been subjected to many surveys of this type, and so residents may still be tolerant of mail questionnaires. Second, it is logical that recent mothers would have a strong interest in the subject of child care. And third, pamphlets on child care were offered to respondents.

One of our interests was in determining the size of the potential audience, that is, the number of families who owned television sets. At least 61 percent and possibly as many as 91 per-

Table 1. Response by race, age of mother, and number of children in family

cent of all families with a child under 1 year of age had sets. The former figure was obtained under the assumption that all nonrespondents were without sets; the latter, under the assumption that all nonrespondents had sets. Among respondents, 86.6 percent, 1,426 of 1,646, owned sets.

There is little doubt that nonwhite families owned proportionately fewer sets than did white families. For example, while 89 percent of the white respondents owned sets, only 69 percent of the nonwhite respondents said that the family had a set. Also, when all persons who did not respond were considered as having television sets, no more than 81 percent of the nonwhite families could have owned sets compared with 92 percent of the white families.

One of the major objectives of the survey was an estimate of the number of women with infants who saw one or more of the programs. Since the sample used in the survey represented one-fifth of the recent mothers in Pittsburgh, such an estimate can be easily obtained by simply multiplying the number of known viewers, 330, by the factor 5 for a result of 1,650. This, however, must be considered a minimal estimate. It is possible that some of the nonrespondents

saw the programs. The largest unknown audience, however, was undoubtedly among mothers in the areas immediately surrounding Pittsburgh, where there are even more births than in the city proper. It is reasonable to assume that the programs were viewed also by others than recent mothers.

The relative size of the audience and whether it varied with such factors as the age of the mother were also of interest. Because some mothers saw the telecasts in homes of relatives or friends even though they did not have television sets and because of the "problems of non-response," the relative size of audience was determined by relating the number of known viewers to the number of persons who presumably received the questionnaire (table 2).

In total, at least 14.1 percent of the mothers watched one or more of the programs. Proportionately, the nonwhite audience was as large as the white audience, in spite of a poorer nonwhite response and evidence that fewer nonwhite families had television sets in their homes. Among white families, as the age of the mother increased or as the size of the family increased, the relative audience size decreased. For example, at least 18.8 percent of the white mothers

under 20 were included in the audience as compared with 12.5 percent of the mothers over 30. The largest audience among the nonwhite mothers consisted of those in their third decade of life.

The initial series of "At Home With Your Child" was produced with very little publicity. A week before the programs began one newspaper carried a feature story in a Sunday supplement. Thereafter an occasional small advertisement was used. In the daily listings of programs, the time period was designated as "Ladies Only" since "At Home With Your Child" was 1 of 5 programs presented at that time of day throughout the week.

The questionnaire included an item which asked the mother if she would have watched had she known of the program. Among 903 women who replied that they had a television set, could receive the educational station, but had not known of the series, 90 percent, 810, said they would have watched had they known of the program. If one accepts their statements at face value and adds the number of known viewers, it means that the audience might have included as many as 49 percent, 1,140 of 2,335, of the recent mothers had the series been widely publicized.

Mothers were asked to specify the number of programs they saw and to indicate which

ones they considered helpful. The 330 women who reported watching the telecasts stated they had seen 1,287 separate programs, an average of 3.9 programs per person. Mothers of only 1 child averaged 3.8 programs; of 2 or 3 children, 4.2 programs; and of 4 or more children, 3.4. Viewers also reported 78.2 percent of the programs seen as being helpful. Mothers with large families found as many programs helpful as did mothers of small families, but their interests were somewhat different. For example, while only 5.5 percent of the mothers with one infant selected "Getting the Child Ready for School" as helpful, 23.0 percent of the mothers with 4 or more children did so. The most popular programs among all mothers were "Baby Gets a Bath" and "Mother's Night Out."

For all family sizes, approximately 84 percent of the respondents requested the pamphlets offered. Mothers who owned television sets requested materials more often than those who did not, 85 percent to 79 percent. Among those with sets, mothers who saw the programs requested pamphlets more often than did those who did not watch, 95 percent to 82 percent. Although this difference suggests that the programs may have stimulated interest in educational materials, there is the possibility that whatever caused the mothers to watch the programs also caused them to request materials.

Table 2. Number of mothers who watched one or more programs

Number of children and age of mother	Number contacted			Watched one or more programs

In other words, they would have asked for the pamphlets without having seen the programs.

Discussion

Until recent years, education on child care offered by health departments was somewhat limited to that given in child health conference service and in the public health nurse home visit. For obvious reasons, these services are usually restricted to the low-income segment of the population and to families where intensive service is required. Within the last few years, however, it has become evident that many parents at the middle- and higher-income levels, using private physicians as their source of medical care and having some knowledge of child growth and development, welcome further information on child care, especially through mass media. The popularity of child care articles in newspapers and magazines is one indication of this kind of interest.

Television, the newest of the mass media of communication, differs from the others in several important ways. Although it is capable of reaching a large number of people at one time, it is also capable of stimulating an intensely personal reaction, second only to a face-to-face situation. It gives the viewer the illusion of being spoken to directly and hence a feeling of close personal contact. The combination of sound and sight, plus the availability in one's own home, contribute to the viewer's feeling of being part of what is being observed.

In the foregoing study of an audience which watched a series of television programs on child care there are indications that television reaches many families who do not receive medical or nursing care from the health department. The estimated television audience slightly exceeded the number of mothers with young babies who attended child health conferences during this same period. Also, the geographic distribution of viewers differed from that of families utilizing child health conference service. Of the mothers in the known television audience, 84 percent were white; but during the period the

programs were telecast, only 50 percent of the mothers who attended child health conferences and 52 percent of the mothers with infants who were visited by public health nurses were white.

The economy of effort possible through the use of television when the goal is solely education is reflected by the fact that 1 physician and 1 nurse produced this series of programs. In order to provide well-child care for a slightly smaller number of children in the same age group, 499 sessions of child health conference were held during the same period of time, staffed by 1 physician and 2 or more public health nurses for each session.

Inasmuch as both the television station and the health department benefit by having as large an audience as possible, it seems logical that both agencies share in the publicity effort. Before the series was repeated in the fall of 1955, the department and the station combined efforts to publicize it as widely as possible throughout the Pittsburgh area. A feature story was carried by one of the large daily newspapers, in addition to the listing in the television section of each of the metropolitan newspapers. Flyers advertising the program were prepared and distributed to new mothers in the maternity divisions of hospitals, to PTA and other parent groups associated with the schools, to women's club groups, and to customers in infants' wear sections of local department stores. The Carnegie Library prepared an attractive leaflet containing a reading list on child care. The leaflets were placed near a poster advertising the program in all Carnegie branch libraries throughout the area.

When the series was telecast the second time, each program was recorded by kinescope, so that the films would be available not only for periodic daytime telecasting but also for showing at other times and to other groups. It is intended to telecast the films during the evening hours when working mothers and fathers are free to view them. The films are also being offered for use in teaching normal growth and development to medical students and nurses and as background material for parents' discussion groups.

For reasons as yet unknown, chemical treatment of privies with dieldrin, aldrin, BHC, and chlordane increases the breeding of Musca domestica, according to CDC studies at Savannah, Ga.

Fly Production in Treated and Untreated Privies

By JOHN W. KILPATRICK, M.S., and H. F. SCHOOF, Ph.D.

PRIOR to 1951 human excrement was not considered to be an important breeding medium for houseflies. However, since 1951 there has been considerable evidence of copious housefly breeding in human feces. Studies in the lower Rio Grande Valley, Tex. (1), and in Phoenix, Ariz., and Charleston, W. Va. (2), have indicated this intensive breeding to be associated principally with the use of dieldrin as a residual or as a larvicidal treatment in privies.

In 1953 the Technical Development Labora-

Mr. Kilpatrick and Dr. Schoof are the co-authors of the article entitled "The Use of Insecticide Treated Cords for Housefly Control," in the February 1956 issue of Public Health Reports (p. 144). Dr. Schoof is chief of the Biology Section of the Technical Development Laboratories, Communicable Disease Center, Public Health Service, Savannah, Ga. Mr. Kilpatrick is an entomologist with the laboratories.

Assistance with the studies reported here was given at the laboratories by Dr. Harold R. Dodge, who identified the majority of the species in the lesser known dipterous groups and helped in processing the copious collections of Diptera, and by Fred Freeman and Bernard O. Smith, who helped in preparing the study structures and collecting the fly samples.

tories of the Communicable Disease Center, Public Health Service, undertook a long-range investigation in southeastern Georgia, near Savannah, to study this paradox of increased housefly production from treated privies. During 1953 the study of fly emergence from 100 untreated privies (10 in each of 10 areas) substantiated the pre-1951 observations that human excrement as a breeding medium normally contributed little to the overall housefly population (3). In 1954 the study plan was designed to determine what effect chemical treatment of privies with certain chlorinated hydrocarbon insecticides would exert upon housefly and other fly production.

Procedure

In 1953 the study included the trapping of flies from 10 privies in each of 10 areas (3). In 1954 the same privies were used in studies as follows:

Series I (Dieldrin and DDT)

(a) Untreated control—20 privies (10 each in 2 areas).

(b) Overall DDT treatment at 200 milligrams per square foot (late March)—10 privies (1 area).

(c) Overall dieldrin treatment at 50 mg./sq. ft. (early April)—30 privies (10 each in 3 areas).

In series Ib and Ic, all animal pens and porches on the premises were treated, as well as the privies. Overall privy treatment included the pits and their contents.

In other words, they would have asked for the pamphlets without having seen the programs.

Discussion

Until recent years, education on child care offered by health departments was somewhat limited to that given in child health conference service and in the public health nurse home visit. For obvious reasons, these services are usually restricted to the low-income segment of the population and to families where intensive service is required. Within the last few years, however, it has become evident that many parents at the middle- and higher-income levels, using private physicians as their source of medical care and having some knowledge of child growth and development, welcome further information on child care, especially through mass media. The popularity of child care articles in newspapers and magazines is one indication of this kind of interest.

Television, the newest of the mass media of communication, differs from the others in several important ways. Although it is capable of reaching a large number of people at one time, it is also capable of stimulating an intensely personal reaction, second only to a face-to-face situation. It gives the viewer the illusion of being spoken to directly and hence a feeling of close personal contact. The combination of sound and sight, plus the availability in one's own home, contribute to the viewer's feeling of being part of what is being observed.

In the foregoing study of an audience which watched a series of television programs on child care there are indications that television reaches many families who do not receive medical or nursing care from the health department. The estimated television audience slightly exceeded the number of mothers with young babies who attended child health conferences during this same period. Also, the geographic distribution of viewers differed from that of families utilizing child health conference service. Of the mothers in the known television audience, 84 percent were white; but during the period the

programs were telecast, only 50 percent of the mothers who attended child health conferences and 52 percent of the mothers with infants who were visited by public health nurses were white.

The economy of effort possible through the use of television when the goal is solely education is reflected by the fact that 1 physician and 1 nurse produced this series of programs. In order to provide well-child care for a slightly smaller number of children in the same age group, 499 sessions of child health conference were held during the same period of time, staffed by 1 physician and 2 or more public health nurses for each session.

Inasmuch as both the television station and the health department benefit by having as large an audience as possible, it seems logical that both agencies share in the publicity effort. Before the series was repeated in the fall of 1955, the department and the station combined efforts to publicize it as widely as possible throughout the Pittsburgh area. A feature story was carried by one of the large daily newspapers, in addition to the listing in the television section of each of the metropolitan newspapers. Flyers advertising the program were prepared and distributed to new mothers in the maternity divisions of hospitals, to PTA and other parent groups associated with the schools, to women's club groups, and to customers in infants' wear sections of local department stores. The Carnegie Library prepared an attractive leaflet containing a reading list on child care. The leaflets were placed near a poster advertising the program in all Carnegie branch libraries throughout the area.

When the series was telecast the second time, each program was recorded by kinescope, so that the films would be available not only for periodic daytime telecasting but also for showing at other times and to other groups. It is intended to telecast the films during the evening hours when working mothers and fathers are free to view them. The films are also being offered for use in teaching normal growth and development to medical students and nurses and as background material for parents' discussion groups.

greatest amount of light. A cone-type trap, constructed of copper wire (36 x 40 mesh) was then attached over the hole. Sponge rubber affixed to the bottom of the plywood base of the trap assured a tight seal. At the end of each trapping cycle the privies were reopened to allow a resumption of fly breeding. (See photographs.)

In privy studies involving only 3 or 4 privies for each type of treatment, the flies emerging from the privies were trapped for 3 weeks, and then the privies were allowed to remain open for the 3 succeeding weeks. Then another trapping cycle was begun.

To evaluate the possible effect of dieldrin resistance on housefly breeding potential in treated and untreated privies, one of the untreated areas was located between 2 treated zones (series Ia) approximately one-fourth mile from either zone. As a result, housefly populations from all 3 areas could intermingle

readily. Pretreatment and post-treatment levels of dieldrin resistance in the fly populations of the various areas were measured. These determinations were made by collecting adult flies from the various areas, obtaining eggs from these flies and testing their progeny by 30-minute exposures to plywood panels treated with dieldrin at the rate of 25 mg./sq. ft. Mortality counts were made at 48 hours.

Untreated Privies (Series Ia)

In the untreated areas (fig. 1), the prevalence of *Musca domestica* was low throughout each entire 12-month period. The largest percentage emergence of *M. domestica* during any one month was 6.3 in 1953 and 16.9 in 1954. Considerable variations occurred from month to month in the total number of flies trapped. This fact can be partly explained by seasonal emergence of various species. *M. domestica*

Figure 1. Percent of *Musca domestica* and other flies emerging from untreated pit privies: 1953 (100 privies) and 1954 (20 privies).

Fly trap in place on privy in Georgia studies.

Series II (Dieldrin, Chlordane, BHC)

(a) 3 privies treated with dieldrin at 50 mg./sq. ft. (August).

(b) 3 privies treated with chlordane at 100 mg / sq. ft. (August).

(c) 3 privies treated with BHC (benzene hexachloride) at 40 mg./sq. ft. (August).

(d) 3 untreated control privies.

Treatment was restricted to the privy contents, riser walls (inside and outside), and the inside of the privy superstructure. All privies were within the same 3- to 4-block area.

Series III (Dieldrin)

Ten privies treated with dieldrin at 50 mg./sq. ft. (August). Treatment made to inside walls of structure and to pits and their contents.

Series IV (Dieldrin and Aldrin)

(a) 3 privies treated (September) with dieldrin at 50 mg./sq. ft. Treatment restricted to the inside of the privy risers. Surfaces not treated were protected from spray drift by paper barriers.

(b) 3 privies treated (September) with dieldrin at 50 mg./sq. ft. Treatment was applied only to the excrement. Adjacent riser surfaces protected from spray drift by paper barriers.

(c) 4 privies treated (September) with aldrin at 50 mg/sq. ft. Treatment applied to the inside walls of the structures and to the pits and their contents.

In evaluating the effects of the dieldrin and DDT treatment (series I) on privy fly production, flies were trapped in 5 privies from each of the 6 areas over a 3-week period. At the end of the 3-week period, flies emerging

from the alternate privies in the same area were trapped. During a trapping period each privy was sealed and made fly tight with the aid of new boards, building paper, masking tape and banked earth around the bottom edges of the building. Each riser was fitted with a seat-hole cover equipped with a spring hinge and lined with foam rubber to provide a close fit when installed over the opening. A hole 6 inches in diameter was cut in the outside wall of the privy approximately 12 inches above ground level on that side of the privy exposed to the

Interior of privy shows seat lid installed.

Figure 3. Percent of *Musca domestica* and other flies emerging from 30 dieldrin-treated privies: 1954.

December despite the fact that during those months housefly activity usually is low. In November, 12,605 flies were trapped, 5,514 of which were houseflies. A majority of the other fly species trapped during this month were either *Desmometopa* spp. or *Leptocera* spp.

Series II, III, IV

Emergence data from the privies (series II) treated with dieldrin, chlordane, and BHC are shown in figure 4. Although these data represent emergence from only 3 privies treated with each chemical, they do show that both chlordane and BHC applications can induce increased housefly breeding similar to that obtained with dieldrin residues. Although applied late in August, the treatments resulted in immediate increases in housefly production in September. In contrast, the untreated privies in the same area (3 to 4 blocks) failed to show any aug-

mentation in housefly production. In general, housefly production from the 3 dieldrin-treated privies was considerably higher in magnitude than that from privies treated with BHC and chlordane.

Treatments were applied early in August to the inside and outside walls and pits of 10 privies (series III) in an untreated area. Pre-treatment emergence of *M. domestica* averaged 1 fly per privy. In October the average housefly emergence was 228 per privy and in November, only 11 per privy. Although housefly production from this group of privies was not extremely high, it does show a significant increase, especially in October. The average production of houseflies from untreated privies during that month was only 7 flies.

Data for the 4 privies treated with aldrin and for the 6 privies that received selective treatments of dieldrin (series IV) are shown in figure 5. Housefly emergence from the 10 priv-

was not a major emerging species at any time, representing only 1.2 percent in 1953 and 2.2 percent in 1954. In regard to 1954, the total fly emergence during the month of highest percentage emergence (August) was the lowest in magnitude (959 specimens) during the April to October period. Thus, the pattern of housefly emergence from untreated privies is similar for both years.

DDT-Treated Privies (Series Ib)

The effect of DDT residual treatments on housefly emergence from privies is shown in figure 2. Although treatment occurred in March, no substantial change in *M. domestica* emergence was noted until July. During that month houseflies represented 29.5 percent of the 1,741 specimens collected. However, of the total of 514 houseflies trapped in the 5 privies during the period, 396 specimens were produced by 1 privy. Subsequent trappings from the

privy failed to show a sustained increase in housefly production so that the apparent increase for a single privy in July appears to be incidental to the general pattern. In general the housefly emergence in the DDT-treated areas was comparable with that from untreated privies.

Dieldrin-Treated Privies (Series Ic)

The percentage emergence of *M. domestica* from dieldrin-treated privies is contrasted with other species in figure 3. Although the 3 dieldrin-treated areas received residual applications early in April, increases in the emergence of houseflies were noted in May. Continued increases of housefly production on both percentage and numerical bases also were evident during the ensuing months in all 3 areas. During August, 87.9 percent of the 20,538 flies trapped were *M. domestica*. Increased emergence was apparent for October, November, and

Figure 2. Percent of *Musca domestica* and other flies emerging from 10 DDT-treated privies: 1954

hilariformis occurred in fewer numbers; however, that was evident both on a pretreatment and post-treatment level. *Telmatoscopus albipunctatus*, although occurring in lesser magnitudes in September and October 1954 than in 1953, was still recorded in considerable numbers in those months (average of 168 per privy in September), and its overall influence on the increased housefly production in dieldrin-treated privies is doubtful.

In general, the changes in prevalences for species other than *M. domestica* were insignificant during the months when the housefly normally is most abundant.

Dieldrin-resistance levels of housefly populations in the treated and untreated areas are shown in figure 6. Pretreatment mortality levels in *M. domestica* from the 3 areas ranged from 53 percent in the untreated zones to 73 percent in the DDT-treated zone. Throughout the entire year mortality levels for houseflies collected in the DDT-treated area were 64 percent or above. In the dieldrin-treated areas housefly resistance increased so that in August 1954 an average mortality of only 1 percent was obtained. Housefly populations in area 5, untreated until September and situated between 2 dieldrin-treated areas, also showed a rapid increase in resistance, a fact presumably explainable by the interchange of flies between the treated and untreated areas. However, the

untreated area, area 6, which was isolated approximately 10 miles from any treated area also manifested an increase in dieldrin resistance that defies a logical explanation.

Discussion

When the 1954 studies were begun, it was anticipated that several treatments and more than one fly season might be required before changes in the species composition of the fly populations would be apparent. However, within 4 weeks after the dieldrin treatments were applied, housefly indexes manifested an increase. The average emergence level per privy for April was 20 *M. domestica*. In May, it was 193, and in July, 1,374. This rapid rise also was evident in the privies receiving treatments with chlor-dane, aldrin, and BHC in early fall. These findings weaken the hypothesis that the cause underlying the increased housefly production is associated with a change in the physiological or behavioristic pattern of dieldrin-resistant strains. Other data antagonistic to this premise are apparent in the absence of increased housefly production in the untreated areas where the level of dieldrin resistance was high.

Despite the chemical treatments of the privies in 1954, it does not appear that any fly species was eliminated. In 1953, 97 species, 65 genera, and 33 families were recorded in emergence

¹ Treatments applied.

² No collections made.

ies during the pretreatment period from May through September was low. However, immediately after treatment in late September, spectacular increases in housefly emergence were evident, ranging from 56.8 percent to 83.7 percent *M. domestica*. The data indicate that aldrin also induces increased housefly production, and they demonstrate that dieldrin treatment of either the riser walls or pit contents is capable of stimulating the production of *M. domestica*.

A more detailed analysis of the data from treated and untreated privies in 1953 and 1954 is shown in table 1. The average emergence of all species of flies from untreated privies in 1953 and 1954 and from DDT-treated privies in 1954 was generally of about the same magnitude. The increase in average emergence for untreated privies in September of 1953 was influenced greatly by the collection of more than 35,000 *Culex quinquefasciatus* during that period. In contrast the total fly emergence from

Figure 5. Percent of *Musca domestica* and other species emerging from dieldrin- and aldrin-treated privies: 1954.

Figure 4. Percent of *Musca domestica* and other flies emerging from 3 privies treated with dieldrin, 3 with chlordane, and 3 with BHC: 1954.

dieldrin-treated privies shows a sharp increase immediately after the treatments were applied. This was particularly evident from July through October.

The average emergence of *M. domestica* alone from treated and untreated privies is also shown in table 1. These data are most significant in that housefly emergence from untreated privies never exceeded an average of 27 flies per privy in either 1953 or 1954, but in September 1954 housefly emergence from dieldrin-treated privies averaged 1,946 flies per privy. As previously stated, the increase in housefly emergence from DDT-treated privies in July 1954 was due primarily to production in one privy. The data for the DDT-treated area in August and succeeding months show that housefly production again reverted to a low level.

A comparative tabulation of the major species which occurred in the untreated privies in 1953 and in the privies treated with dieldrin in the spring of 1954 shows the average fly emergence per privy by months (table 2). Although variations in the magnitude of different species occur, the significance of these fluctuations appears of little consequence with the exception of *M. domestica*. *Dendrophonina*

Figure 6. Dieldrin resistance levels in housefly populations in untreated areas: 1953 and 1954.

the survival of either species. Quantitative evaluation of *H. illucens* as a breeder in privies was not obtained since the 3-week trapping period employed was less than the developmental period of this species.

The 1954 data established several additional points:

1. Increased housefly production can be induced by residual treatments of BHC, aldrin, and chlordane as well as by dieldrin applications.

2. Dieldrin treatment of pit contents alone or of riser walls alone augments housefly production.

3. In the same general area of 3 to 4 blocks, treatment of privies selected at random increased housefly production, but untreated privies showed no augmentation.

None of these points defines the factor or factors responsible for the increase in production of *M. domestica*. The possible exclusion of a competitive agent, parasite, or predator is suggested by the last two points above, but little difference is apparent in the types of arthropods frequenting the treated and untreated privies. Both DDT and dieldrin are known to persist for extended periods, yet the effect of each is

different on housefly production. In contrast, aldrin, which has little residual action, produced results similar to dieldrin.

Despite the absence of any clear-cut explanation for the phenomenon, it is obvious that treatment of privies with certain chemicals increases rather than decreases housefly production from that source. Since *M. domestica* is the principal house-frequenting species, the chance of disease transmission is likewise augmented. Since untreated privies produce few houseflies, it is apparent that chemical treatment of privies should be avoided.

Further studies are now in progress in an attempt to define the factor or factors responsible for the increase in housefly production in privies treated with various chlorinated hydrocarbons.

Summary

During late March and early April 1954, near Savannah, Ga., 30 privies were treated with dieldrin, 10 privies with DDT, and 20 privies remained untreated. Within 4 weeks the dieldrin-treated privies showed a sharp increase in housefly production. Average monthly indexes per privy were 193, 254, 1,374, 1,204, and

traps. In 1954, 123 species, 76 genera, and 36 families were recorded as coming from both treated and untreated privies. The only flies taken in 1953 and not present in 1954 were of the family Bibionidae, and only token numbers of this group were taken in 1953. Of the specimens collected in 1954, 273,046 flies (38,306 from the untreated areas and 234,740 from the treated areas) were identified; 90,209 were houseflies. Of that number, 88,443 were taken from privies that had been treated with dieldrin, and only 1,766 were taken from

an equal number of either DDT-treated (945 houseflies taken) or untreated (821 houseflies taken) privies. The species captured are listed in the accompanying insert (p. 796).

It was noted that in untreated privies larvae of the soldier fly, *Hermetia illucens*, were extremely prevalent, whereas in dieldrin-treated privies they were either absent or present in small numbers. However, in laboratory cultures seeded with *M. domestica* and *H. illucens* together in varying numbers, there appeared to be little or no detrimental effects upon

1955 Summary of Disease Outbreaks

By CARL C. DAUER, M.D., and GRANVILLE SYLVESTER

ONE OF THE characteristic features in the pattern of disease in man has been a constant change from one predominant type of illness to another. This is true even if one limits his consideration to infectious diseases. Some of the acute infections have receded with respect to incidence and others with respect to severity. Certain diseases, especially viral infections, have appeared to increase in frequency or have become relatively more important because of recession of bacterial infections. These changes may have resulted from alteration in the biology of infecting agents, different host-parasite relationships, the development of immunizing agents, improvement or deterioration in social conditions or in the environment.

The pattern of diseases in which food and water have acted as vehicles of infection has also changed. The number of waterborne outbreaks of typhoid fever and dysentery, and of milkborne outbreaks of enteric infections, diphtheria, and streptococcal infections has been reduced from several score each year to an average of less than 10. Even though reporting is far from complete there is no reason to believe that this is not a real decrease in waterborne and milkborne illness.

As these types of disease have decreased, the number of outbreaks in which foods other than milk and milk products have been vehicles of infection has become proportionately greater

and possibly some types have increased in frequency. It is probable that changes in eating habits have been responsible in part for the relative increase in outbreaks of staphylococcal food poisoning and undifferentiated gastroenteritis. Mass preparation and dispensing of foods in a greater number of public eating places and schools have increased the chances of exposure to contaminated foods. It appears that the solution of human problems has not kept pace with improvements in processing and equipment and provisions for sanitation of equipment. The human problems most frequently mentioned are poor food-handling practices and failure to use adequate refrigeration of foods susceptible to contamination.

Waterborne Disease Outbreaks

During the last 3 years there has been a continuous reduction in the number of outbreaks attributed to water—from 14 in 1952 to 7 in 1954. In 1955, there were only two outbreaks in which water was definitely incriminated. Although the exact number of cases is unknown, it is by far the smallest in recent years. In 1954, the total, 452 cases, was less than that for previous years. During 1955 one outbreak occurred among fire fighters in the mountains. They had filled their canteens from a water tank previously used to pump cesspools. The number of cases is unknown because none was very ill, and all continued with their duties. The other outbreak was among school children whose water supply was from a well contaminated by a nearby septic tank. Twenty-two cases were reported, and the investigation revealed *Escherichia coli* in the well water. Al-

Dr. Dauer is medical adviser to the chief, and Mr. Sylvester is analytical statistician with the Morbidity Analysis Section of the National Office of Vital Statistics, Public Health Service.

Fly Species Collected in Privy Studies

BORBORIDAE: *Borborus* spp., *Leptocera* spp., *Leptocera ferruginata*, *L. fontinalis*, *L. venalicia*, *Sphaerocera* spp., *Sphaerocera equinus*, *S. varipes*.

CALLIPHORIDAE: *Calliphora livida*, *C. vicina*, *Callitroga macellaria*, *Cynomyia* *cadaverina*, *Phaenicia caeruleiviridis*, *P. cuprina*, *P. sericata*, *Phormia regina*.

CHLOROPIDAE: *Ceratobarys eulophus*, *Hippelates pusio*, *H. bishoppi*, *H. dissidens*, *H. flaviceps*, *Madisa cinerea*, *Monochaetoscinella nigricornis*, *Oscinella* spp.

CHRYOMYIDAE: *Chryomya flava*, *C. salmarius*.

CULICIDAE: *Aedes vexans*, *Anopheles quadrimaculatus*, *A. crucians*, *Culex quinquefasciatus*, *C. erraticus*, *Culiseta melanura*, *Mansonia perturbans*, *Orthopodomyia signifera*.

DOLICHOPODIDAE.

DORILAIIDAE.

DROSOPHILIDAE: *Drosophila busckii*, *D. affinis*, *D. guttifera*, *D. melanogaster* group, *D. repleta*, *D. robusta*, *Drosophila* spp., *Mycodrosophila dimidiata*.

EMPIDIDAE: *Drapetis divergens*, *Drapetis* spp.

EPHYDRIDAE: *Discocerina brunneonitens*, *Discocerina* spp., *Gymnopa* spp., *Paralimna decipiens*, *Scatella stagnalis*.

FUNGIVORIDAE.

HELEIDAE.

HELOMYZIDAE: *Amoebaleria defessa*, *Diastata ornata*, *Pseudeleria pectinata*, *Tephrochlamys reflexiventris*.

ITONIIDAE.

LAUXANIDAE.

MUSCIDAE: *Atherigona orientalis*, *Cocnosia* spp., *Dendrophana scabra*, *D. querceti*, *Fannia canicularis*, *F. femoralis*, *F. howardi*, *F. manicata*, *F. pusio*, *F. pusio* group, *F. scalaris*, *Fucellia maritima*, *F. americana*, *Graphomya maculata*, *Hebecnema halterata*, *Hydrotaca acuta*, *H. houghii*, *H. occulta*, *Hylemya cili-*

crura, *Limnophora arcuata*, *L. cilifera*, *Musca domestica*, *Muscina assimilis*, *M. aurantiaca*, *M. stabulans*, *Ophyra aeneascens*, *O. leucostoma*, *Schoenomyza* spp., *Scopeuma furcatum*, *Stomoxys calcitrans*, *Synthesiomyia nudiseta*.

OMPHRALIDAE: *Omphrale fenestralis*.

OTITIDAE: *Delphinia picta*, *Euxesta notata*, *Ricella* spp.

PHORIDAE.

PHYLLOMYZIDAE: *Desomometopa* spp., *D. m-nigrum*, *D. tarsalis*, *D. tibialis*, *Leptometa latipes*, *Milichiella arcuata*, *M. lucteipennis*, *Stomosis luteola*.

PIOPHILIDAE: *Piophilina* spp.

PSYCHODIDAE: *Brunettia nitida*, *Phlebotomus vexator*, *Psychoda alternata*, *P. severini*, *Telmatoctopus albipunctatus*.

SARCOPHAGIDAE: *Hypopelta scrofa*, *Sarcophaga* spp., *S. bullata*, *S. anandra*, *S. argyrostoma*, *S. assidue*, *S. derelicta*, *S. floridensis*, *S. galeata*, *S. haemorrhoidalis*, *S. importuna*, *S. laakei*, *S. latisetosa*, *S. morionella*, *S. ochracea*, *S. plinthopyga*, *S. pusiola*, *S. rapax*, *S. sarcacenioides*, *S. singularis*, *S. ventricosa*, *Sarcophaga* spp., *S. impar*, *S. salva*.

SCATOPSIDAE: *Scatopse fuscipes*, *S. notata*.

SCIARIDAE: *Bradysia* spp., *Sciara* spp.

SEPSIDAE: *Meroplus stercorarium*, *Sepsis punctum*.

STRATIOMYIDAE: *Hermetia illucens*.

SYLVICOLIDAE: *Sylvicola altanatus*, *S. marginatus*.

SYRPHIDAE: *Meromacrus acutus*, *Tubifera tenax*, *T. dimidiatus*.

TENDIPEIDAE.

TETHINIDAE: *Pelomyia coronata*.

TIPULIDAE: *Mumetopia occipitalis*.

TYLIDAE: *Taeniaptera lasciva*.

1,946 specimens for May through September, respectively. In contrast, average monthly indexes for the same period for DDT-treated and untreated privies were 15, 7, 103, 14, and 36, and 3, 13, 5, 16, and 10 specimens, respectively. Nine privies within a 3- to 4-block area, treated in groups of 3 with BHC, dieldrin, or chlordane, also showed increased housefly production with a low prevalence persisting in 3 adjacent untreated privies. Both aldrin-treated privies and dieldrin-treated privies with only the riser walls or the pit contents sprayed likewise produced increased housefly breeding. A total of 273,046 flies, representing 123 species, 76 genera, and 36 families, were trapped in all privies.

The low level of housefly production in un-

treated privies and the increased breeding of this species in privies treated with BHC, chlordane, aldrin, and dieldrin indicate that the use of these chlorinated hydrocarbon insecticides for housefly control in privies should be avoided.

¹ Includes outbreaks among military personnel, not listed in any State.

were reported, both of which resulted from a carrier. Of the outbreaks from salmonella infections, two were definitely associated with carriers, and it is believed that many more resulted from unknown carriers. In many instances, the source of outbreaks was not determined, but evidence of improper handling and

lack of adequate refrigeration was found to be a contributing factor in most of the outbreaks.

Typhoid Fever

The number (5) of typhoid fever outbreaks reported in 1955 was relatively small compared

though not proven, water was a possible vehicle of shigella infection in two children in a summer camp. It was also a possible source of nine cases of infectious hepatitis among school children at a camp.

Milkborne Disease Outbreaks

The number of outbreaks associated with milk and milk products has not been large (fewer than 10) in each of the last 5 years. In 1955, there were 302 cases in 3 outbreaks compared with 200 cases in 9 outbreaks in 1954. While there were only 6 outbreaks in 1952, the number of cases was about 800. Most of the cases (278) reported during 1955 resulted from 1 outbreak in which commercial milk was the vehicle. An investigation revealed a salmonella organism, group B.

The other 2 outbreaks reported in 1955 resulted from milk products contaminated with *Staphylococcus aureus* during the manufacturing process. In one, 15 cases developed after eating ice cream made in an old freezer which apparently had not been thoroughly cleaned. Contaminated cheddar cheese was associated with nine cases. Since staphylococci were found in the center of cheese from unopened samples, it was concluded that contamination occurred during the manufacturing process.

Other Foodborne Outbreaks

With only a few outbreaks in which milk and milk products were associated, naturally, a great majority have been from other foods. The total outbreaks associated with other foods reported in 1955 was 193 with 9,633 cases compared with 234 outbreaks and 11,704 cases in 1954. Reports for 1955 were received from 27 States, Hawaii, and military establishments compared with those from 35 jurisdictions in 1954.

As in 1954, foods most frequently incriminated were turkey and chicken (including eggs), custard filled pastries, ham, and beef. However, unlike previous years when potato salad was the vehicle in a number of outbreaks, there were only two associated with this food in 1955. Various other foods were associated with

¹ Includes outbreaks among military personnel not listed in any State. ² Not available.

the remainder. In one outbreak the vehicle appeared to have been contaminated by a food handler who had hepatitis. No foodborne hepatitis was reported in 1954.

During the year only two shigella outbreaks

coccal food poisoning. However, the 102 reported in 1955 indicate little change as compared with the 100 for 1954. A number of these outbreaks were confirmed by bacteriological examination, *S. aureus* being isolated in 15 instances. No reports of the isolation of *Staphylococcus albus* were received. In 1954, there were 23 isolations of *S. aureus* and 3 of *S. albus*.

Epidemiological investigation in most instances failed to determine the source, but inadequate refrigeration and improper food handling were usually found. An infected food handler was found in a large number of the outbreaks associated with poor handling procedures. Unsanitary conditions were found to be contributing factors in several outbreaks. About a fourth of the outbreaks were attributed to public eating places and another fourth to private households. A smaller number of outbreaks were associated with bakeries, schools, and field lunches. Hospitals, church gatherings, and picnics were sources of only a few outbreaks.

Streptococcal Infections

A total of 353 cases of streptococcal food poisoning was reported in 4 outbreaks. One outbreak was among employees and student nurses in a hospital. About 54 hours after egg salad was served in 2 dining rooms, 116 persons became ill with streptococcal sore throat. A streptococcus was isolated from the salad and from the kitchen helper who prepared it. The helper was ill prior to reporting to work on the day he prepared the egg salad.

Another outbreak involving 181 school children developed 3 days after they had eaten ham in the school cafeteria. Bacteriological examination of the ham revealed *Streptococcus faecalis*. The meat was found to have been improperly handled. One outbreak not associated with food occurred among employees of a restaurant. No secondary cases resulted from this source, indicating none of the food was contaminated by the employees.

Chemical and Other Noxious Agents

Five outbreaks involving 99 cases resulted from noxious agents. One was from *Nicotiana glauca* mistaken for polk weed, and the other

four were attributed to chemicals. One involving 50 children resulted from a dye (now prohibited) used to color popcorn. Another was from nicotine sulfate used as a spray on mustard greens. The third was from nitrite in wieners because of faulty processing. Cadmium was incriminated in the fourth and affected 25 persons.

Trichinosis

Ninety-two cases of trichinosis were reported in 5 outbreaks during 1955. Of these cases, 69 were in one outbreak among 111 members of two fraternities. Each maintained its own dining room and served "rare" pork to the members, who preferred this type of meat. No large outbreaks occurred in 1954, thus fewer cases were reported that year. However, in 1953, the case total was 134 including an outbreak affecting 73 persons in an institution. Two of the 1955 outbreaks were associated with bakeries, schools, fed hogs. Rats seen on the farms supplying the meat were a possible source of infection of the swine.

Gastroenteritis

Numerous outbreaks of gastroenteritis were reported in 1955. Epidemiological investigations of these failed to determine the etiology in all but a few. The majority were believed to have resulted from food; 2 were traced to water, and 1 to a beverage. The method of contamination was not found but improper handling of food was associated with many of the outbreaks. Inadequate refrigeration was a contributing factor in many instances. The accompanying table shows these and miscellaneous outbreaks, such as the 4 of streptococcal food poisonings with 353 cases. Also, included in the table are 2 outbreaks from paracolon organisms which affected 90 persons and 5 outbreaks probably of viral origin. A total of 922 cases was reported in these viral outbreaks.

For 16 outbreaks, although food was suspected to be the vehicle of infection, no specimens were available for bacteriological examination, and no specific item was incriminated. In other outbreaks there was sufficient evidence that a particular food was involved but in many instances none was available for laboratory

with the 16 in 1954, 12 in 1953, and higher numbers in previous years. One outbreak involved 21 cases in 5 related families that had contact with a carrier. Two other outbreaks were traced to carriers, one of whom was a domestic in a private home and may have contaminated food. The source of the other outbreak was not found. It occurred on an Indian reservation where a number of possible modes of spread were found, but sufficient evidence was lacking to incriminate any of these.

Salmonellosis

Thirteen outbreaks of salmonellosis were reported in seven States during 1955. This is half the number reported in 12 States and 1 Territory for 1954. Three additional outbreaks among military personnel were reported in 1955 compared with none in 1954. The total (971) cases was 17 percent less than the 1,164 cases for last year, but it is about 82 percent greater than the 533 reported in 1953.

All except one outbreak were associated with food. The exception was among persons who attended Pan American games in Mexico, and the source was not determined. In one outbreak at least 278 people supplied by one dairy were affected. Another large outbreak with 250 cases resulted from rice patties served in an institution. *Salmonella montevideo* was isolated from the rice patties, but the source of contamination was not found. In a second institution 6 persons became ill from the ingestion of frozen eggs. *Salmonella pullorum*, commonly associated with eggs, was isolated from the frozen product.

Of the remaining outbreaks, 6 were in private households, 1 in a restaurant, 1 in a club, and 1 in a hospital's newborn nursery. In only 3 of the outbreaks was a carrier found, 1 in the dairy, 1 in the hospital nursery, and 1 in a local store which sold fishcakes to the general public.

Other than those mentioned above, the *Salmonella* organisms isolated were *alachua*, *anatum*, *chester*, *enteriditis*, *newington*, *newport*, *thompson*, and *typhimurium*, and also group B. Three organisms were isolated in connection with one outbreak, and no specific etiology was assigned to it.

Shigellosis

During 1955 half (5) as many States reported outbreaks of shigellosis as in 1954. This is reflected in the number (10) of outbreaks compared with that (19) for last year. The number of cases (475) is considerably less than the 1,471 reported in 1954, probably because of the distribution of the outbreaks.

In 1955, only 2 outbreaks among children were in institutions, 1 among children in a hospital, and none among school children compared with 17 in these organizations during 1954. The majority of the outbreaks this year were in rural or substandard housing areas. Two cases developed in children in a camp and followed fecal contamination of soil or water, or both.

One outbreak involved 45 persons who attended a wedding reception. An investigation revealed that this was a catered reception, and all food items probably were contaminated by the caterer who was found to be a carrier. One other outbreak resulted from food and the remainder was considered person-to-person transmission.

Six of the outbreaks were from sonne types of organisms and 4 were flexner types. Only 3 outbreaks were traced to carriers, the source of the other 7 being unknown.

Botulism

Five outbreaks of botulism were reported in four States during 1955. Of these, 2 were of type A organisms and 2 were of type B. The other was based on clinical evidence and was not confirmed by laboratory tests. Home canned foods, olives, chili peppers, spinach wild mushrooms, and chayote were incriminated. In one outbreak 5 individuals became ill after eating chili peppers while at work. The person who prepared the food was accused of canning various foods and had canned chili peppers many times before without incident. All five of the victims recovered after receiving botulinus antitoxin. However, of the other 9 cases reported, 7 resulted in death.

Staphylococcal Food Poisoning

For the last several years increases have been noted in the number of outbreaks of staphylo-

in two outbreaks. One of these outbreaks was in Florida, but cold weather set in and no mosquitoes could be collected for laboratory tests. The other outbreak was in North Carolina where several hundred horses and mules died as a result of the disease. The virus was also found in mosquitoes.

Outbreaks of diarrhea among newborn infants were reported by three States. Thirty-seven infants in six hospital nurseries developed the disease from contact with a carrier or improper sterilization procedures or both. *E. coli* was found in specimens of patients in two outbreaks and other coliform organisms were found in specimens collected in another. No reports of laboratory examination were given for the other outbreaks.

Unusual occurrences of diphtheria were reported, particularly during the latter half of 1955. For the entire year, six outbreaks of the disease were reported. Most of the cases associated with these outbreaks were among people in the lower socioeconomic group. Immunization levels in the affected areas were found to be dangerously low.

Reports of 13 outbreaks of infectious hepatitis were received from five States and Alaska. The mode of spread in most of these was given as personal contact, but some spread probably resulted from fecal contamination. Poor personal habits were given as a possible mode of spread in a few instances.

Food was determined to be the vehicle of infection in 13 cases in one outbreak. Water was suspected in two outbreaks, but there was insufficient evidence to incriminate it. In one, use of unsanitary buckets by members of a football team was considered the source; in the other, polluted water from a stream in a picnic area, used in making a cold beverage, was a possible source.

Five of the outbreaks occurred in hospitals or institutions. Four were among students. The other four were among general populations in localized areas. Although not an outbreak, 201 cases were reported in one city. Of these, 45 were diagnosed as serum hepatitis, or there was a recent history of contaminated needles and instruments.

Auxiliary Publication

Public Health Reports frequently receives contributions which, though worth documenting, pose technical or financial difficulties which prevent their acceptance for publication. Thanks to the American Documentation Institute, it is possible now to provide a reference and a central source for such material by the following process.

The author of qualified material will be asked if he wishes to have the material deposited in the ADI auxiliary publication program file at the Library of Congress, for a nominal fee (\$2 for the present). If he is willing, *Public Health Reports* will publish a note to the effect that the material, briefly described, with a document number, is available from that source.

Such materials submitted by the editor will be accepted by the American Documentation Institute in the Library of Congress, entered in

the auxiliary publication program file and catalog, and held indefinitely, awaiting requests for copies. Copies will be furnished at the regular rates of the Library of Congress photo-duplication service.

Such material must satisfy the regular scientific and editorial criteria of this journal. The editor's decision against publication in this journal must be dictated by financial and technical considerations only. The material may consist of an entire paper or a portion of it, illustrative, supplementary, or appendical in nature. The program does not apply to books, doctoral dissertations, or other material published separately. Authors should not offer material directly to the Library of Congress. Material may be forwarded for deposit with the auxiliary publication program only by the editor of a scientific, learned, or professional journal.

tests, or, on testing, no pathogenic organisms were found. The average incubation period was found to be much longer than the 4 to 6 hours usually found in staphylococcal food poisoning. This suggests food infection, some of which may have been salmonella infections. As suspected vehicles, poultry meat was mentioned almost twice as often as any other food, followed by beef, and a few each of creamed filled pastries, fish, and creamed meat or salads.

Five outbreaks probably of viral origin were reported, 2 in schools, 2 in institutions, and 1 in a mountain camp. Viral studies were done in at least two but in none was the etiology definitely established. However, investigations did rule out food and water as vehicles of infection. One large outbreak not listed in the table occurred among the general population in Ohio and was spread by personal contact to approximately 3,000 persons.

Animals as Sources of Human Disease

Animals are important factors in diseases of man in several respects. They may be reservoirs of infection which may be transmitted to man by direct or indirect contact. Animal products in the form of food (meat, milk, and eggs) may also be sources or vehicles of infection. Some animal products (hides, hair, and wool) may harbor pathogenic organisms which can infect man.

The importance of animals as sources of infection for man is shown by the fact that 80 different diseases may be transmitted to man. Nearly one-half of the diseases listed for reporting by States to the Public Health Service are in this category. The wide distribution of some of these infections is shown by the following figures: 48 States reported human cases of brucellosis in 1954, 41 reported tularemia, 38 reported Rocky Mountain spotted fever, and 32 reported one or more cases of psittacosis.

Animal food products such as meat, milk, and eggs may not only serve as vehicles of infection from the animal to man but they also are excellent media for the growth of bacterial agents. Poultry meat and eggs are occasionally sources of infection, mostly salmonella infections, or are contaminated during the period of prepara-

tion by organisms causing food intoxication or food infection.

In 1955, there were 30 such outbreaks reported in which about 1,600 cases of illness occurred. Of these, 25 were associated with meat and 5 resulted from eggs. Seven outbreaks, 4 from poultry meat and 3 from eggs, involving 162 cases resulted from salmonella infections. Of those associated with meat, the sources were unknown but epidemiological investigations revealed lack of adequate refrigeration. In one the meat was probably contaminated by a carrier. However, this was not definitely established because three organisms were isolated, none being from the meat itself.

S. pullorum was isolated from frozen eggs associated with one outbreak. In another, the organism was not isolated from eggs but there was good evidence that they were contaminated with *S. thompson*. In the third outbreak, there was insufficient evidence of contamination in the eggs although they were eaten by all those affected.

Fourteen outbreaks were from staphylococcal enterotoxin, 1 from streptococcus, and 7 were of unknown etiology. As would be expected in the staphylococcal poisonings, improper food handling was a common finding. Many of those with unknown etiology probably were salmonella infections because the incubation periods were longer than is usually associated with staphylococcal poisoning.

Miscellaneous Outbreaks

Three outbreaks of meningitis were reported. One was among preschool and school children in western North Carolina. Another affected two children in a family in Utah. The other occurred among Indians on a reservation and involved eight persons during a 2-week period.

Although two outbreaks of encephalitis occurred among pheasants, no outbreaks of infectious encephalitis were reported in humans during 1955. The prevalence of the disease in California, where it is endemic during the summer months, was markedly lower in 1955 than in 1954. A few laboratory confirmed cases of arthropod-borne infections were received from various parts of the country. Eastern equine encephalitis virus was isolated from pheasants

Diphtheria Decline Slower in South

Reviewing diphtheria morbidity and mortality data prepared by the Communicable Disease Center of the Public Health Service, Atlanta, Helen A. Moore, M.D., chief of the Diphtheria Surveillance Unit, and Grace I. Larsen, nurse officer, said that diphtheria, despite its dramatic decline, is still a residual problem in the United States, particularly in the south.

Some 2,000 cases of diphtheria are reported every year in the United States, and the fatality rate remains about 6 to 9 percent, they said. Diphtheria cases still outnumber reported cases of brucellosis, encephalitis, psittacosis, typhoid fever, or, plus, as well as smallpox, malaria, human rabies, or anthrax, and its importance as a public health problem should not be minimized, they added.

Sample findings from the study,

which is being prepared for publication, follow.

Since 1930, diphtheria decreases have been greater in the north than in the south. Seventy percent of the Nation's diphtheria cases between 1950 and 1954 occurred in the South Atlantic, East South Central, and West South Central States.

Moore and Larsen presented maps (see sample) and charts to analyze the incidence.

In the past, both diphtheria case rates and death rates recorded for Negroes have been only a fraction of those recorded for the white population in the southern States. Now, case rates are as high for nonwhite and in some instances are even higher.

Moore and Larsen said: "Intensified immunization programs among Negro children in the south is still 'young diphtheria' despite a proportional increase in incidence among adults in other parts of the country. In Georgia, considered

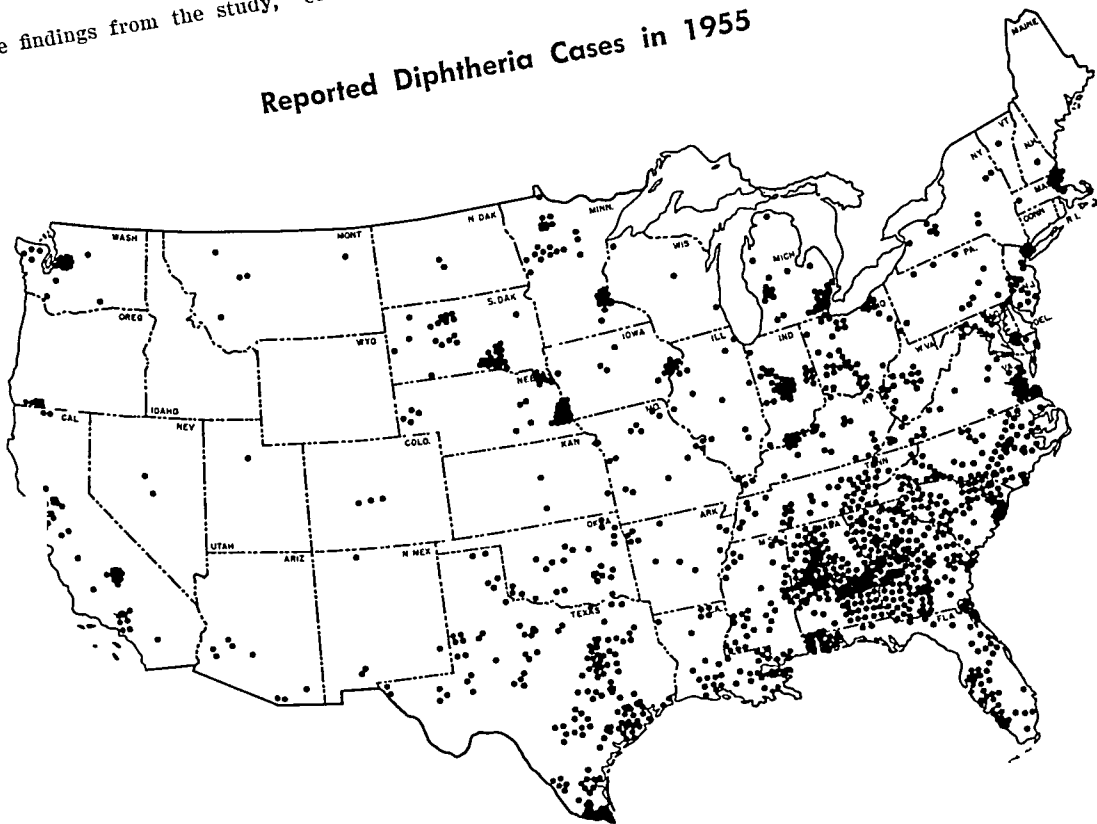

typical, the highest rate was in the age group 1 to 4 years until 1948. Since then the rate for children 5 to 9 years old has been nearly as high or higher.

Moore and Larsen said: "The Georgia experience, which has been paralleled by a similar experience in Kentucky, may hint that a shift in age distribution of cases might occur in the southern area, perhaps not a shift to adults but to older children . . . This would point to a need, not only for very early immunization but for continued immunization throughout school life."

The diphtheria season in the southern States occurs earlier than in other parts of the country. The season can be expected to begin in July or August and to reach a peak in October.

Moore and Larsen said: "This peculiarity of season makes it vital that late summer cases be recognized so that infection may be kept out of schools as far as possible. It is equally vital that children be pro-

APHA SOUTHERN BRANCH CONFERENCE REPORT

The Southern Branch of the American Public Health Association held its 24th annual meeting April 4-6, 1956, in Tulsa, Okla. Many of the papers read accented the theme of the meeting by demonstrating how some southern communities are benefiting from the advances in public health practice.

News summaries of 12 of the papers are presented here. The encouraging report that local health agencies are adopting a vector control program after successful demonstration projects in several States is the subject of one. In Missouri, another reports, educational activities in farm counties helped bring about enactment of an effective State brucellosis control law. A downward trend in dog rabies is noted in Kentucky, where public opinion brought about a State law for compulsory immunization of the canine population.

Success in a program for the care of the chronically ill was reported from Richmond, Va. In Tulsa, Okla., the health department has an active voice in controlling land improvement, and in Georgia studies show that local mosquito control programs ought to start in late winter.

Other papers discussed demographic changes in the south, a method for determining the costs of administering the poliomyelitis vaccine, psittacosis control, criteria for a local mental health program, and the problem that diphtheria still presents to the southern States.

Attending the meeting were public health workers from Alabama, Arkansas, District of Columbia, Florida, Georgia, Kentucky, Louisiana, Maryland, Mississippi, Missouri, North Carolina, Oklahoma, South Carolina, Tennessee, Texas, Virginia, and West Virginia.

limited to milk ordinance cities in which the local health department requested tests. The bureau was also instrumental in getting tests in the three larger metropolitan areas in the State.

The rate found in the cross-section survey compared favorably with the 37.7 percent rate of infection found in 67,000 dairy herds by the Missouri Department of Agriculture in 1953 in the first statewide ring tests, Price said.

Other phases of the statewide survey were voluntary blood testing at the owner's expense and intensified calfhood vaccination. In a second round of statewide milk ring testing in 1955, the infection rate had dropped to 18.5 percent in 148,177 herd tests. Blood tests of 776,087 cattle during the same period showed 22,141 reactors, or an infection rate of 2.8 percent for brucellosis.

In an epidemiological investigation in 1953-55, the Missouri Division of Health attempted to ascertain the frequency of human brucellosis in a rural area, the probable mode of transmission, and the most prevalent species of *Brucella*.

The study area was confined to 18 counties in district 3 in west central Missouri, a diversified farm area that produces some milk for the Kansas City market. However, most of the dairies are small and produce ungraded milk.

From blood specimens submitted to the bureau of laboratories for routine agglutination studies, all subjects with blood agglutination titers of 1:80 or higher were selected for this epidemiological study.

Of the 62 investigations completed, 35 of the patients were acutely ill and 20 had chronic cases, according to their physicians. (Four did not have brucellosis; 1 veterinarian and 2 veterinary students were not investigated.)

Twenty-eight (80 percent) of the 35 acute illnesses were found in persons having direct contact with infected animals or their discharges, and 7 (20 percent) were attributed to the consumption of infected raw milk or milk products.

Cultures were attempted on all

specimens, and 9 isolations were identified, all of them *Brucella abortus*. Seven of the isolations were from the 28 cases attributed to animal contact (2 of them might have been swine contact), and 2 were from 7 cases of probable milk origin.

The epidemiological findings, Price concluded, compare with those elsewhere in the midwest, with the exception that in this area of Missouri the primary causative agent thus far isolated is *Brucella abortus*.

Kentucky Reducing Rabies In Dog Population

Public opinion in Kentucky was so aroused after a Louisville boy died in 1953 from the untreated bite of a stray dog that rabies immunization for dogs became compulsory in 1954.

Ronald L. Hectorne, D.V.M., director, division of veterinary medicine, Kentucky State Department of Health, said that under Kentucky's 2-year-old rabies law the State department of health is responsible for vaccinating all dogs and the State department of agriculture for licensing dogs, collecting strays, and maintaining dog pounds. Local health departments were asked to set up vaccination clinics in cooperation with local veterinarians.

More than 4,000 clinics have been held since the act became effective on July 1, 1954, and more than 200,000 dogs have been vaccinated.

To serve eastern counties, in which there are few accredited veterinarians, a veterinarian has been employed to conduct clinics. In other counties lacking a resident veterinarian, veterinarians from neighboring counties have come in to conduct clinics. In this way, the State with the cooperation of the Kentucky Veterinary Medical Association has overcome a major obstacle in administering the law.

During the 2-year period ending December 31, 1955, 125,652 dogs had received the chick embryo (avianized) vaccine, and 81,193 the brain tissue vaccine. The chick embryo vaccine is used at all local clinics sponsored by the health department.

Dogs vaccinated in the clinics wear a standard tag containing the vaccine manufacturer's name, the serial number of vaccination, and the year of vaccination. The color of the tags is changed each year.

The success of the program is shown in the downward trend of rabies in the dog population. Laboratory-confirmed rabies has been reduced from an average of 398 positive cases during the 5 years before 1954 to 261 in 1954 and 120 in 1955. Rabies infection verified in dog heads submitted for examination has fallen from 44 percent in 1953 to 30 percent in 1955.

Rabies in wildlife, however, is on the increase in the State, Hectorne reported. The State health department and the Kentucky State Fish and Wildlife Department are trying to reduce the fox population.

Florida Sets Tentative Cost For Administering Vaccine

Preliminary calculations indicate that 64 cents is the cost of administering a single injection of poliomyelitis vaccine in Florida. Since 90 percent of all poliomyelitis vaccine distributed by the Florida State Health Department goes to county health departments, a time-cost study was run in 5 selected counties to estimate administration costs for the entire State.

Representing the county health department in Orange County, Wade N. Stephens, M.D., M.P.H., Orlando, explained how the estimated figure was derived. Time-cost records were kept in health departments in Franklin, Gulf, Leon, Orange, and Wakulla Counties for 7½ months, ending February 29, 1956.

The per dose cost of administration to the local health department is found by dividing local cost by number of doses given (table). The sum of individual employee costs plus cost of supplies, excluding vaccine, equals the monthly cost of the poliomyelitis program to each health department.

To obtain individual employee costs, multiply the total hours worked each month by an employee

tected by immunization before entering school. Ideally, of course, they should be immunized during infancy with only a recall immunization needed before school entry."

Setting Up Rabies Control In the Health Department

If canine rabies is to be prevented, restraint of the dog population, operation of the pound, and the anti-rabies vaccination program should all be centralized within the communicable disease program of the local health department, asserted Luther E. Fredrickson, D.V.M., M.P.H., public health veterinarian, Tennessee Department of Public Health.

"A most important element in public education is a well-managed pound, kept odor-free, with a system of accurate records," he added.

Fredrickson had concrete suggestions for organizing efficient dog control:

1. Legislation should provide that the dog shelter and the rabies control officers be under the supervision of the health officer; that all personnel have civil service protection; that owners be required to secure vaccination of their dogs; that a public health veterinarian direct the program. The ordinance should be supplemented with regulations.

2. Dog wardens and control officers must be skilled in meeting the public in addition to being adept at handling dogs.

3. A thorough record system, set up by an experienced auditor, is fundamental. It must incorporate a method of accounting, recording of cash, and auditing.

Forms for investigation of complaints on straying dogs should be filed for future reference after a complaint is closed. A daily summary should describe each dog received. A signed statement from the owner or harbinger of the dog involved in a biting incident will clear the dog surrendered for destruction or adoption.

Tags will facilitate identification of lost dogs. Owners should be notified. Proper forms for recording the location and condition of biting dogs

during the period of quarantine are necessary to physicians treating victims of dog bites.

4. Equipment should be designed to provide for easy cleaning, protection of personnel, and proper care of the dog.

A thorough daily cleaning schedule will keep the pound and vehicles free from obnoxious odors.

Equipment for the pound should include various types of brushes, facilities for the hot detergent as well as a sanitizing agent, and a well-designed sewer system. Water taps, hot and cold, should be at convenient locations.

The examination room should be equipped with tables for vaccinations, examinations, and autopsies, with refrigeration for vaccine and the preservation of dog carcasses pending laboratory examination, and with hot and cold running water.

Ventilation of collection vehicles should be designed so that children are not able to reach through the openings to pet a dog. The vehicle bed should provide drainage. Metal is the most suitable material for the truck compartments.

Secure, individual compartments for rabies suspects are necessary both in the truck and at the pound. A separate section of the shelter should be reserved for cages of rabies suspects.

5. The areas of the community in which rabies control officers can best prevent new cases of animal rabies can be determined by epidemiological studies.

Areas that have yielded rabid animals should be intensively patrolled. Strenuous efforts must be made to locate animals and persons bitten by a rabid dog. Exposed animals should be destroyed immediately, or, at the minimum, quarantined for 6 months.

Areas with low percentages of vaccinated dogs should be given particular attention. Sections where less than 80 percent of the dog population is protected by current vaccination are likely sources of rabies outbreaks.

6. The public ought to visit the pound, except where rabies suspects are quartered. Visitors can learn from employees how the community

is protected against rabies. The dog shelter may be included in the field trips planned for school children.

Missouri Gains Legislation For Brucellosis Control

Missouri's activities in brucellosis control, culminating in an effective State law in August 1955, were reported by Edmund R. Price, D.V.M., public health veterinarian and assistant director of the bureau of communicable diseases, Missouri Division of Health.

The high prevalence rate of brucellosis was indicated in a 1951 Federal report, stating that 6.7 percent of the cattle in the State were positive to the blood agglutination test.

The Missouri Division of Health had urged adequate legislation for years, but its efforts were accelerated in the past 5 years, Price indicated. The division conferred frequently with leaders of the several brucellosis committees that had been appointed since 1940 to advise on legislation. Projects included an education campaign, a milk ring test survey, and an epidemiological investigation of human brucellosis cases.

In 1951, four copies of the film "The Triple Threat of Brucellosis" were made available to all the schools, PTA's, and farm and civic organizations through the division's bureau of health education. Several hundred thousand persons, in urban as well as rural areas, saw this film. In many counties, health personnel used the film as a primary part of their school health education program. In other counties, the local health departments held area symposiums on brucellosis. Many radio scripts and newspaper releases were prepared for local use. Thousands of pieces of literature were sent out by the bureau of health education, and all of the State health agency's envelopes carried the postmark "Stamp Out Brucellosis."

The milk ring tests, conducted in 1952 by the division's bureau of laboratories, yielded a brucellosis infection rate of 38.2 percent in 708 herds supplying 6 cities. The survey was

pneumonias and ill-defined fevers, he asserted.

Interstate shipments of parakeets are so large and numerous that North Carolina's present program of investigating bird populations suspected as the sources of human psittacosis infections and destroying aviaries where infection is found seems grossly inadequate, he declared.

Vector Control Projects Found Successful

The key to the encouraging success of the community vector control demonstration program has been its acceptance by the public, according to Charles E. Gerhardt, M.S., vector control consultant to the Communicable Disease Center of the Public Health Service.

Local health agencies have adopted permanent programs of environmental sanitation for vector control on a par with such programs as food, milk, and water sanitation, he asserted.

Demonstration projects at Pueblo, Colo., and Kansas City, Kans., have been completed. Projects at Laredo, Tex., Boise, Idaho, Cedar Rapids, Iowa, and Gadsden, Ala., are current, he reported.

In one area, Gerhardt said, 500 cesspools were replaced with proper facilities; in another area, 1,800 outdoor privies were razed. Miles of sewer extensions have been laid, and several million dollars worth of bonds have been approved for future extensions.

At all projects, garbage and refuse storage, handling, and disposal practices have been notably improved, and, he added, the improved practices have been adopted by a number of nearby cities. In several communities the application of the recommended garbage and refuse handling methods resulted not only in an improved environment for the control of communicable diseases but in savings of more than the cost of the demonstration program. Also, he said, some property and land values increased, and some previously unusable land was reclaimed.

Industry has been cooperative, Gerhardt commented, in correcting major problems of industrial wastes disposal, and the keeping of large animals in cities has been eliminated or controlled through enforcement of legislation.

Participation in Projects

A city or county is selected for a demonstration project on the basis of vectorborne or related disease problems, location in relation to other cities, need for general improvement in environmental sanitation, the attitude of local government officials and citizens to change, and ability to finance the program. Direct requests from State and local health authorities also have a bearing on the decisions, Gerhardt said.

Federal participation consists primarily of providing a technical supervisor, assigning vehicles, and supplying spraying equipment, training, and educational aids. The technical supervisor is assigned to the local health agency for a period of 2 years. He conducts the program according to State and local health department policy.

Of primary importance is the assignment by the local health agency of a qualified person to assist the technical supervisor with surveys, evaluation, project details, and who will take over direction of the program when the technical supervisor leaves, Gerhardt asserted. The local health agency also provides office and shop space, manpower, chemicals, enactment and enforcement of necessary legislation, and obtains interdepartmental cooperation.

Endorsement of the project by the State is a primary requisite, he said. State participation in the project varies according to State policies. Some States supply travel funds for observers from other cities.

Development Procedures

Gerhardt mentioned procedures in the development of a typical community vector control demonstration project, including a community-wide survey to evaluate and delineate insect vector problems; legislative needs; garbage, refuse, and industrial waste handling and dis-

posal standards; animal maintenance; extension of sewerage systems; insect and rodent control; and educational activities.

Education is vital to the success of the program and is used in a "do-it-yourself" context. The community thus develops its own skills, abilities, and interest. Such interest is the best assurance that the program will be actively continued and supported after Federal participation is withdrawn, Gerhardt said.

Mental Health Action Criteria Outlined

The director of a local mental health program must deal with the interrelationships of all individuals in the community. His decisions affect the behavior of the public and bring about action to destroy adverse predisposing influences and to nurture favorable ones, said Guy V. Rice, M.D., director of health conservation services, Georgia Department of Public Health.

All action promoted by the health officer in developing a community mental health program, Rice said, occurs in the following places: the home (including the hospital), the church, the school, the "factory," and the playground. It will pertain to one or more of the following factors: understanding and acceptance, replacement and substitution, anticipatory guidance, "built-in reactor," and support.

Specific Programs

Rice listed eight specific programs which he said can bring about improvement of a community's mental health:

General education to bring about understanding of mental illness and to dispel fear and stigma.

Attack on maternal deprivation through relocation of children with their mothers or arrangement for care by a permanent mother substitute.

Preparation for physiological or other crises, such as childbirth, caring for an infant, adolescence, and old age, by providing educational material or holding special classes.

Cost of giving vaccine in 5 Florida counties

County	Total local cost ¹	Doses administered	Cost per dose
Orange	\$4,165 88	6,367	\$0 65
Leon	2,687 46	8,093	33
Gulf	1,149 64	1,033	1 11
Franklin	582 21	223	2 61
Wakulla	772 46	493	1 57
Total	\$9,357 65	16,209	\$0 58

¹ August 12, 1955, to February 29, 1956

by his hourly wage, calculated on the basis of a 40 hour week. To this amount, add the number of miles he travels, multiplied by 7½ cents.

To obtain an approximation of the total local cost throughout Florida, multiply the average cost per dose in the five counties by the total number of doses given throughout the State: \$0 58 (average cost per dose, from table) × 228,264 (total doses given in State) = \$132,393 12 (total local cost in State).

Add to this the State administration costs: \$132,393 12 (local cost) + \$14,779 03 (State cost) = \$147,172 15 (total cost).

To calculate the total cost per dose, divide the total cost figures by the number of injections given: \$147,172 15 (total cost) ÷ 228,264 (number of injections) = \$0 64.

Changes in Demography Challenge Public Health

Future population growth of the south will take place in urban areas, stated Matthew Tayback, Sc D, di-

rector of the statistical section, Baltimore City Health Department. He based this prediction on trends in population growth and movement since 1920.

Discussing the implications for public health of this and related demographic trends in the south, Tayback urged public health authorities to reconsider their responsibilities. Of particular importance, he said, are these characteristics of an urban culture: (a) families have limited contact with their relatives, (b) large numbers are crowded into small areas, and (c) the rigid discipline of hours and methods of labor creates mental and emotional stresses.

Tayback considers adequate coverage of the population with medical and nursing skills the first essential for a sound preventive medical program. To a large extent, he said, this coverage can be provided through existing services of personal physicians and hospital centers. But in many instances, facilities for diagnosis of cancer, detection of early emotional disorders in children,

home nursing care, and the like, are lacking.

"The public health department will demonstrate its maturity and usefulness to the modern urban community by the statesmanship it exhibits in the solution of such unmet needs," he declared.

The full text of Tayback's presentation is scheduled for publication in the *American Journal of Public Health*.

Says Psittacosis Control Should Start Now

Two approaches to the problem of controlling psittacosis were suggested by Martin P. Hines, DVM, MPH, chief, veterinary public health section, North Carolina State Board of Health.

The first is to accept the fact that direct control over birds carrying the virus is not possible or practical and to direct attention and efforts toward alerting the public and physicians to the dangers that exist, he declared.

The second is to consider reestablishment of a Federal ban on interstate and import shipments of psittacine birds except from certified aviaries. This would not be possible without funds, he asserted. If the cost of certified birds could be kept between \$15 and \$20 bird certification would be practical, he thought.

He described a number of psittacosis infections in humans that occurred in North Carolina and pointed out that the veterinary section is at present investigating 50 psittacosis cases. He claimed that the source of infection in North Carolina is parakeets, and, "with the exception of Texas and Oregon, it is the same elsewhere."

The incidence of psittacosis was low prior to 1951 when the Federal ban on interstate shipment of psittacine birds was lifted, Hines said, but during the past 4 years the incidence has increased almost 800 percent. The degree of increased psittacosis incidence will not be known until physicians are alerted to suspect psittacosis in atypical

Florida Refines Cost Figure

A final study, completed June 30, 1956, is expected to show more precisely the cost of administering a single injection of poliomyelitis vaccine in Florida. In developing the 64-cent figure reported on this page, Dr. Stephens had as his immediate purpose the demonstration of a method of estimating the cost. In April 1956 Dr. Joseph Bistowish of Tallahassee completed a similar study in which he found 36 cents to be the cost of administration per injection. There is reason to believe that the actual figure is still lower.

was one of the weaknesses of the old system, in which home care was provided by physicians employed part time and hospital care was provided on a contractual basis by the Medical College of Virginia Hospital. The only records were charge slips. Physicians on home care did not see their patients in the hospital or outpatient clinics and received no reports from these services.

Under the new program, comprehensive medical care is provided through agreements and contacts with hospitals, clinics, nursing homes, and institutions for the incurably ill. The use of the patient's home for medical care is extended through use of the housekeeper service of the Family Service Society and equipment from the Sickroom Loan Chest. The Instructive Visiting Nurse Association and the Richmond Department of Public Health's nursing service, functioning as a combined unit, provide bedside nursing and public health services for patients on a referral basis. (A detailed description of the program was published in *A Study of Selected Home Care Programs, Public Health Monograph No. 35, 1955.*)

Another feature of the medical care program for the indigent is the dental clinic organized in 1950. It is sponsored jointly by the Richmond Department of Health and the School of Dentistry of the Medical College of Virginia.

Nursing Services

Increasing demands for bedside nursing services led to the establishment of a combined nursing unit in which the Department of Public Health and the Instructive Visiting Nurse Association participate. Set up first as a demonstration project for South Richmond, the combined unit became citywide in January 1953.

Appraisal of the combined unit after 3 years' experience shows it to be economical and efficient, Holmes and his colleagues remarked. It provides better quality care and eliminates duplication of services. These advantages, they said, have made possible the provision of the bedside nursing care required by the new home care program.

Special Clinic

In 1954, a committee was designated by the community council to study the problem of facilities for the handicapped child. The committee recommended that a diagnostic and evaluation clinic be established, that it be operated cooperatively by at least the Department of Public Health and the Medical College of Virginia, and that all related voluntary health agencies participate in the planning and financing.

On the strength of these recommendations, a governing board was established early in 1955. Under the leadership of this board, the Richmond Council of Jewish Women, the Medical College of Virginia, and the Department of Public Health, supported by 13 voluntary agencies, undertook to set up the proposed clinic. In November 1955, the clinic held its first session in facilities provided by the Medical College of Virginia.

Tulsa's Health Department Helps Plan City's Future

In Tulsa, Okla., described as a "frontier village that had burst its seams," the health department has joined local city and county agencies in planning for the long-range expansion of the city and its environs beyond its present boundaries, according to Clyde B. Eller, director of the sanitation division of the Tulsa City-County Health Department.

The instrument through which unincorporated subdivisions in the counties surrounding Tulsa are achieving orderly growth is the Tulsa Metropolitan Area Planning Commission. Established in April 1953, the commission was created to cut across red tape hampering postwar efforts to control land improvement. A health department representative is a member of the technical review board of the commission.

Long-Range Studies

Long-range planning and comprehensive zoning by the commission are developing patterns for tomorrow's thoroughfares, freeways, parks, shopping centers, and other com-

munity facilities for neighborhoods as yet unborn, Eller stated. The health department is sharing in these projects by planning an air resources study to avoid the necessity of an air pollution control program 20 years hence, by conserving and rehabilitating housing in present transition neighborhoods, and by seeking to anticipate future garbage collection and disposal problems, he added.

Eller said that the commission passes on the basic design of proposed subdivisions: on size, arrangement, type of streets and intersections; on access, size, and shape of lots; on location of easements and building of setback lines; provision for offstreet parking; public open spaces and other requirements.

In addition, the health department, through its representative on the commission's technical review board, passes on the adequacy of present land improvements which might affect the planned network of future streets, water lines, and sewers, Eller said. Many of the regulations under which the commission operates were drafted with health department advice and with the department's open support in public hearings, he added.

Eller quoted portions of two regulations as illustrative of the requirement that proposed water supply and sewage disposal systems have health department approval.

Approval Procedure

Eller also explained the procedure by which subdivision developers obtain approval of sanitary installations:

The planning commission reviews the preliminary subdivision plat for obvious inconsistencies with design standards, then schedules it for discussion at the next weekly meeting of the technical review board. At that meeting, attended by the developer and his engineer, the plat receives detailed, constructive review by representatives of the city, county, and traffic engineer, the water and sewer department, the health department, and the planning staff. If warranted, representatives

Special education for leaders, beginning possibly with teachers since teachers train the future leaders of the country. (Studies by the Army and others have shown that units commanded by persons following sound principles of leadership, including a more permissive attitude toward their men, have fewer casualties resulting from emotional disturbances than units commanded by persons who do not recognize individual responsibility.)

Supportive services for families of the mentally ill, possibly as a part of a generalized public health nursing program.

Treatment in general hospitals for the mentally ill. The public health department could underwrite and supervise treatment for those unable to pay, as it does for patients with cancer, tuberculosis, or other diseases.

Custodial care with long-term treatment for those who do not respond to rapid, intensive treatment in the general hospital.

Special guidance for children exhibiting emotional disturbances not likely to be resolved by eliminating the adverse influence of maternal deprivation.

Research and Evaluation

In determining the action needed in the community and evaluating the program once it is under way, it is necessary to develop criteria to use in selecting priorities, Rice stated. He listed the following criteria developed by the local and State mental hygiene staffs of the Georgia Department of Public Health:

The degree to which there is—

1. Readiness for the services on the part of the community or the administrative unit.
2. Potential for reaction with or effect on persons in positions of authority.
3. Facilitation of communications and prevention of isolation among communities, administrative units, and individuals.
4. Enhancement of personality growth and development.
5. Active public interest.
6. Potential for raising the gen-

eral level of mental health services in the community.

7. Potential for the prevention of mental illness.

8. Potential for community self-appraisal.

9. Socioeconomic capacity of the administrative unit or community to support the service.

10. Potential for integration with other services or programs.

Not only have these criteria been of value in determining what action is needed, but the process of outlining them has given us a better understanding of our own program, Rice declared.

After the director has reviewed the possible programs which he might develop and has weighed them against the criteria to determine their priority and has decided which to include, he must then decide what type of staff will be necessary to accomplish the objectives. Rice urged that the utmost care be exercised in selecting staff. Not only must their professional qualifications fit them for the job, but their personal ones as well, he said.

Blends City's Services For Long-Term Patients

Joint planning of health programs by civic groups and voluntary and official health agencies, a method used in Richmond, Va., since 1906, has proved particularly effective in care of the chronically ill, according to a report by four members of the Richmond Department of Public Health.

The four members are: E. M. Holmes, Jr., M.D., M.P.H., director of public health for Richmond; P. W. Bowden, M.D., M.P.H., chief of the bureau of preventive medical services; W. R. Harton, Jr., B.S., chief of administrative services; and Alan N. Young, B.S., chief of health information. All are on the staff of the Medical College of Virginia.

Civic groups are brought into health planning through the Richmond Area Community Council. Through contracts and agreements with the official agencies, a large part of the voluntary agencies' funds is

expended for joint or cooperative projects.

The report by Holmes and his associates outlined the community council's work on chronic illness and related problems during the past 8 years. Council recommendations have been followed in reorganizing the medical care program for the indigent, forming a combined health department-visiting nurse association nursing service, and establishing various clinics.

The council initially assigned special subcommittees to study (a) existing hospital, nursing home, and convalescent facilities; (b) the community's rehabilitation facilities; and (c) facilities for medical and nursing care in the home.

The study of nursing home and convalescent care facilities, they said, revealed a great shortage of beds for Negro patients, a marked preponderance of beds for white women, and the problem of slow turnover of patients. It also showed that the cost in many homes was beyond the financial means of a large portion of the population. Another subcommittee offered the following recommendations:

1. That full use be made of private nursing home facilities on a contractual basis.

2. That the City Home, an institute for the care of the aged administered by the city's welfare department, be converted to a nursing home.

In 1953, the conversion of the City Home was accomplished. Admissions are coordinated through the health department's bureau of medical aid, which assures the use of the home as an integral part of the chronic disease medical care program.

Home Care Program

Richmond's present medical care program for the indigent is based on recommendations of the community council subcommittee assigned to study the health department's home medical care services. This program, according to the report, provides both quality of care and continuity of service from the home to the hospital and back to the home. Lack of continuity of service

technical publications

Civil Defense Information for Food and Drug Officials

Food and Drug Administration Publication. Unnumbered. 1955. Compiled and edited by Lowrie M. Beacham, Jr., and Harold V. Leininger, Homer J. McConnell, Joseph A. Mathews, and Alan T. Spiker, Jr. 188 pages; illustrated.

The basic information about nuclear, radiological, chemical, and biological warfare agents in this civil defense handbook is designed to give food and drug officials, confronted with the aftermath of an attack, knowledge that will permit them "to decide what must be done and how it can be accomplished."

Part 1 covers postattack problems and operations and summarizes the probable duties of a food and drug official should an attack occur. Part 2 presents the scientific aspects of radioactivity, fusion, fission, and fission products, biological effects of ionizing radiation, chemical warfare agents, and the fundamentals of biological warfare. Part 3 reviews the basic scientific tools for a better understanding of radiology.

A limited number of copies of the handbook are available to those with civil defense responsibilities, without charge, from the Food and Drug Administration, Washington 25, D.C.

Guide to Making a Survey of Patients Receiving Nursing and Personal Care

Public Health Service Publication No. 454. 1955. By Jerry Solon, Dean W. Roberts, and Dean E. Krueger. 55 pages; exhibits. 75 cents.

This guide, an outgrowth of a specific study by the Commission on Chronic Illness and the Public

Health Service, presents a tested method for States and local communities to use in discovering what types of patients and care are found in establishments or programs that provide nursing or personal care. Thirteen States participated in the study. Interest of other States has led to the issuance of the survey methodology for general use.

The types of information studied include personal and social characteristics of the patients, their medical condition, nursing care and attendance by physicians, activities engaged in, charges incurred, and sources of funds for care.

Interest in such a study may stem from health and welfare planning groups, standard-setting and licensing authorities, public welfare agencies financing care of clients, and from owners, governing bodies, and administrators of the facilities. To them the manual offers a method of conducting a survey, providing for their use a survey schedule, classification of facilities, techniques for collecting data, editing and coding instructions, and tabulating procedures.

Nursing at the Clinical Center

Public Health Service Publication No. 468. 1956. 12 pages; illustrated.

A two-color, illustrated booklet just published describes the opportunities available to nurses in the Clinical Center of the National Institutes of Health.

The brochure explains how nurses serve as important members of the medical research teams, the clinical services to which they may be assigned, and what the typical nursing unit is like. By means of questions and answers, detailed information is given about the kind of training re-

quired, the salaries to be expected, and the opportunities for advancement.

The pamphlet is available to nursing schools, State nursing registers, hospitals, State and local health departments, and other agencies concerned with nursing activities.

Patients in Mental Institutions, 1952

Part I. Institutions for Mental Defectives and Epileptics

Public Health Service Publication No. 483. 1956. 56 pages. 35 cents.

Based on the 27th annual census of patients in mental institutions, this report is the first part of the sixth such census to be conducted by the National Institute of Mental Health.

For the first time since its inception in 1923, the annual report will be published in four parts, permitting a more expeditious and flexible medium of presentation. The other parts, *Public Hospitals for the Mentally Ill*, *Private Hospitals for the Mentally Ill*, and *General Hospitals With Psychiatric Facilities*, and *Private Institutions for Mental Defectives and Epileptics*, will follow. Pending the publication of these parts, information on subjects treated therein may be obtained from Dr. Hyman Goldstein in the Biometrics Branch of the institute.

This section carries announcements of all new Public Health Service publications and of selected new publications on health topics prepared by other Federal Government agencies.

Publications for which prices are quoted are for sale by the Superintendent of Documents, U. S. Government Printing Office, Washington 25, D. C. Orders should be accompanied by cash, check, or money order and should fully identify the publication. Public Health Service publications which do not carry price quotations, as well as single sample copies of those for which prices are shown, can be obtained without charge from the Public Inquiries Branch, Public Health Service, Washington 25, D. C.

The Public Health Service does not supply publications issued by other agencies.

of public utilities and of other local, county, and State groups also are present.

Their comments are used by the developer to revise his preliminary plat for presentation at the next convenient weekly meeting. The plat then passes to an official citizens' commission for approval, and the developer can proceed to prepare the final plat for filing.

If sanitary sewers are not available at the time the preliminary plat is submitted, the results of at least one soil percolation test and one 48-inch core test per acre are required. The plat must also be accompanied with an accurate topographic map. This material, together with aerial photographs and information obtained from field trips and actual experiences in nearby areas, permits careful analysis of all conditions. In the event that semipublic or private water supplies are planned, the availability of adequate, potable water must be substantiated in the form of information from test wells

or affidavits from competent geologists or nearby residents with wells.

These regulations apply both to formally platted subdivisions and to small tracts or lots, Eller stated, adding that all applications for proposed sanitary installations within the jurisdiction of the commission must be submitted to the health department.

House Mosquitoes Breed During Georgia Winter

In Georgia from the fall line southward, *Culex quinquefasciatus*, the tropical house mosquito, breeds and survives throughout the winter, according to studies in Columbus and other cities of the State in 1955-56. These studies were reported by Orlin K. Fletcher, Jr., M.P.H., biologist, Georgia Department of Public Health, and Leon Flanagan, insect control officer, Muscogee County (Ga.) Health Department.

This evidence suggests the need for

starting mosquito control operations in late winter, Fletcher and Flanagan indicated. They reasoned that reproduction and survival of the mosquitoes during the winter results in a buildup of the mosquito population early in the spring and summer.

In Columbus, the studies demonstrated the presence of egg rafts, larvae, and both male and female adult mosquitoes in the street catch basins during most of the fall and winter months. Similar conditions were observed in other cities of the State.

Even in abnormally cold weather, they said, the mosquitoes are occasionally so numerous as to create control problems. In Columbus, complaints of biting activities became so vociferous in December that it was necessary to larvicide the street catch basins in one section of the city. In Baxley, complaints were received with such frequency during the winter months that routine larviciding operations were continued throughout the winter.

Course in Laboratory Diagnosis of Tuberculosis

A course in laboratory methods in the diagnosis of tuberculosis will be offered by the Public Health Service under the joint sponsorship of its Division of Special Health Services and its Bacteriology Laboratories of the Communicable Disease Center, Chamblee, Ga., from January 21 through February 1, 1957.

All grades of employed laboratory personnel, including laboratory directors and senior laboratory staff members, who are approved by their State health officers are eligible for the course.

Practical laboratory training in all phases of tuberculosis bacteriology, including preparation of culture media, microscopy, cultural procedures, diagnostic use of animals, and testing of drug sensitivity will be included in the course.

No tuition or laboratory fees are charged. Reservations for this course should be made well in advance.

Information and application forms may be obtained from Laboratory Training Services, Communicable Disease Center, Public Health Service, P. O. Box 185, Chamblee, Ga.

Flood waters carried animal carcasses, garbage, and rubbish through Winsted, Conn., in onrushing tide. Heaps of rubble had to be sprayed with insecticides. The Public Health Service shipped stores of these plus chemicals for rat control to New England from its Communicable Disease Center in Atlanta.

Sunday, August 21, saw the arrival in the Pennsylvania flood area of 55 sanitation personnel from all sections of the State. Health workers in other States responded with similar alacrity.

Public Health Service Assistance

Traditionally, the Public Health Service role in supporting State public health services is entirely supplementary, filling in where other health services are lacking or in need of reinforcement.

The first Public Health Service personnel

were dispatched from Region II in New York City on Saturday, August 20. By Friday, August 26, the maximum complement had been assigned to disaster-aid duty. In some instances, selected personnel completed special assignments and withdrew. Other specialists were assigned later. All told, 45 Public Health Service officers were assigned for flood disaster duty to the State departments of health, the Federal Civil Defense Administration, and the National Red Cross.

Public Health Service sanitary engineers assigned to State health departments in the affected areas assisted in evaluating incoming

The Sanitary Engineer in Hurricane Floods

By FRANK TETZLAFF, C.E., M.C.E., K. C. LAUSTER, B.S.M.E., M.S.P.H.E.,
and RICHARD S. MARK, B.S.S.E.

WARNED by radio and newspaper stories on the morning of Friday, August 19, 1955, Public Health Service engineers in the New York regional office curtailed normal activities in readiness for Hurricane Diane.

The anticipated calls for assistance failed to come in during the day. By Saturday morning, August 20, the reasons became clear: Communications had failed, and few people were aware of the immensity of the disaster. In some States, authorities had to wait for the floodwaters to recede before they could determine what assistance would be required. Nevertheless, 10 inches of rain in a 24-hour period over an area extending from the Poconos in eastern Pennsylvania, across the Catskills and Berkshires, and into Connecticut and Massachusetts portended a national emergency.

Not until the following week did the extent

of damage become known. Experience could lend no clue. There was no previous record of so great a rainfall. In northwestern Connecticut, the maximum rainfall was estimated at 20 inches.

The newspapers quoted a general in the Army Corps of Engineers as saying, "Floodwaters have caused more damage in Connecticut in 2 days than all of the strategic bombing in the Ruhr Valley during the entire World War II."

In Winsted, Conn., floodwater from the Mad River reached 9 feet above any known previous record.

Easton, Pa., reported the Delaware River 5 feet above the previous maximum record.

A 300-year-old house in Connecticut, never before flooded, was swept away.

A 100-year-old dam in the Peekskill, N. Y., area had 7½ feet of water over its spillway. The previous record was 4 feet.

Three miles of a 36-inch water supply main was washed away at Scranton, Pa.

Diane came with such destructive force, augmented by bursting dams, that everything in her path was wrecked or damaged. Pavements were torn up. Watermains were ripped out. Highway and railroad bridges were destroyed. Houses and factories were obliterated. Automobiles were tossed around like toys. Worst of all, nearly 200 people were killed.

State health agencies mobilized their personnel immediately and deployed them into the stricken areas. The first arrivals were to make a quick reconnaissance and report on the need for additional assistance, equipment, and supplies.

Mr. Tetzlaff is chief, Headquarters Engineering Activities, Air Pollution Control Staff, Division of Sanitary Engineering Services, Public Health Service, Washington, D. C. At the time of the hurricane floods, he was regional engineer, Public Health Service Region II, New York City, and Mr. Lauster was assistant regional engineer. Mr. Lauster is now sanitary engineer consultant, Health Office, Federal Civil Defense Administration, Battle Creek, Mich. Formerly chief engineer and then deputy director of the Public Health Division, Economic Cooperation Administration Mission to Greece, 1948 to 1952, Mr. Mark is assistant regional engineer in the New York office.

Shattered, splintered avalanches of debris settled on city streets as flood waters roared through Waterbury, Conn. Food stores and other sources of necessities became inaccessible islands in a sea of wreckage like this.

The State health departments issued "boil water" notices in communities where contamination was suspected or known to exist. Heavy chlorination of the water was practiced. Breaks in the water systems were repaired. The "boil water" notices were in effect until water samples were bacteriologically satisfactory. In many communities the usual gas and electricity were not available for heat, and millions of chlorine (halazone) disinfecting tablets had to be distributed along with emergency supplies

of safe drinking water when piped water was not available. For drinking water many communities had to rely on emergency filtration equipment or on water brought in by milk-tank trucks, obtained from individual and school wells located on high ground or from other temporary supplies.

Milk supplies, in general, were not disrupted. The total milk supply was adequate. Raw milk supplies from dairies or pasteurization plants affected by floodwaters or power fail-

reports or in coordinating with the department staff and with the Federal Civil Defense Administration and the Army Corps of Engineers. Some were reassigned to county or local health departments or were deployed in the field as representatives of the State sanitary engineer. These groups functioned as personnel of the State or local health department to which they were assigned, and their authority stemmed from State or local authority.

Several sanitary engineers were detailed to the Federal Civil Defense Administration to appraise damage to sanitary facilities and to determine priority of the cleanup operations. Project applications submitted by local officials to the Army Corps of Engineers for restoration of damaged community facilities were first certified as to public health need by Public Health Service officers under Public Law 875 (81st Cong., 2d sess.). Public Law 875 authorizes the expenditure of Federal emergency funds by the Federal Civil Defense Administration. Accustomed as they were to working with State health departments, it was only natural for public health experts to follow similar procedures in this special assignment and to coordinate disaster activities among the various State, Federal, and volunteer agencies.

Officers assigned to the American National Red Cross appraised damage to individual homes and to other forms of housing. Cash allowances by the Red Cross for restoration of private property were based in large part on the appraisals they made.

To meet the Public Health Service's various responsibilities, the New York office drew on other branches of the Service for temporary duty personnel. The Chicago, Kansas City, Dallas, and Atlanta regions, the Washington, D. C., headquarters, the Robert A. Taft Sanitary Engineering Center in Cincinnati, and the Communicable Disease Center in Atlanta assigned Public Health Service officers to disaster-aid duty in the northeastern States.

Twelve Commissioned Reserve Corps officers on inactive status were called to active duty from the city health departments of Cambridge, Mass., Hartford, Conn., Pittsburgh, and Philadelphia; from the housing rehabilitation project in St. Louis; from Vanderbilt University in Nashville, Tenn.; from the State health de-

partments of New Mexico, Oklahoma, Tennessee, and Virginia, and from the health departments of Caroline County, Md., and Mecklenburg County, N. C.

In New York, the regional engineer and his two assistant regional engineers directed Public Health Service activities in the cleanup. The other engineers on the staff were assigned to emergency field duty.

Interstate Carrier Sanitation

The only direct responsibility of the Public Health Service was for interstate carrier sanitation in the flooded area—the sanitation of water, milk, and food supplies which were used by interstate carriers and which might be affected in any way by the floods. Two sanitation specialists checked the condition of railroad watering points in the flooded areas. Their assignment was to find out from State and local waterworks officials whether supply sources for the watering points were affected by the floods and to notify carriers, by telephone or telegram, about the supplies which were unsafe.

Ten watering points were put on prohibited status until the water was safe for use and the sanitation satisfactory. One watering point was still on prohibited status as late as November 15, 1955. One company supplying ice cream to interstate carriers was placed on prohibited status. That action was necessary because floodwaters had temporarily disrupted the city water supply.

Field assignments for Public Health Service sanitary engineers ran the gamut from liaison with State and Federal groups to the organization and direction of spray crews, garbage disposal operations, and other "feet-wetting" tasks at the local level.

The rehabilitation of the 55 municipal water supplies which were either totally or partially interrupted was handled primarily by State health department personnel and by municipal water departments or by private water companies and their consulting engineers. In this connection, the mutual-aid system of neighboring communities assisting each other, which was set up during World War II, and which has been maintained continuously ever since, was highly valuable.

About 35 Federal food and drug inspectors were sent out to look for contaminated food and to supervise its destruction. The inspectors investigated the chance that prescription drugs might have been swept into the open where they could be picked up.

Much of the equipment and materials for conducting sanitation operations were available generally because the stricken areas were near sources of needed supplies. Thus, fortunately, chlorinated lime, insecticides, chlorinating equipment, pumping equipment, bulldozers, and draglines were available. In addition, the Public Health Service contributed power sprayers, hand-pressure sprayers, warfarin rat-bait concentrate, malathion fly-control concentrate, DDT concentrate, red squill rat-bait pellets, halazone tablets, typhoid vaccine, tetanus antitoxin, and penicillin.

Housing sanitation criteria developed by Public Health Service officers in cooperation with the local health officers determined when homes could be reoccupied. Local personnel

were trained in consistent interpretation of the criteria.

Before residents were permitted to return to their homes, building inspectors checked the structural safety of each damaged building. Emergency sanitarians inspected each home to see that there was no water in the cellar and that the mud and silt had been removed; that there was no excessive dampness; that a water supply was available; that at least one sink and one water closet were in operation; that sewer lines were open; that walls, floors, and ceilings were clean and did not present any hazards; that electric wiring and fixtures were safe and satisfactory; that stoves and furnaces were clean and ready for use; and that fire hazards had been removed.

ures were diverted and handled through other plants.

Interruptions to sewage treatment and sewer service were not serious. Removal of debris that prevented sewage from flowing in the lines and that caused ponding in some residential areas was the main problem. Floodwaters backing up in a drainage pipe in one sewage treatment plant—the pipe did not have a shut-off valve—caused an estimated \$70,000 damage to motors, sludge-heating equipment, and electrical control equipment. The plant itself was not affected by floodwaters overtopping the entrance, but the structures of two activated-sludge tanks, empty at the time of the flood, were damaged. High groundwater caused the tanks to rise.

Water and Sewer Systems

Sanitary engineers detailed to the Federal Civil Defense Administration were assigned to survey and report on the damage and the cost of temporary repairs to water and sewer systems, on the need for removal of debris, and on other sanitation needs of significance.

The following report of a Public Health Service sanitary engineer describes a typical situation encountered.

"Since none of the small towns I visited had either a water commissioner or a sewer superintendent, and only one had a city engineer (who had nothing to do with streets or utilities), the mayors or councilmen, usually laymen, needed engineering assistance and guidance. One seriously damaged small community which I visited 2 weeks after the flood had seen no public officials from the outside. They were trying to help themselves by renting heavy machinery for cleanup at a cost of \$600 per day, with no assurance as to how the rental fee was to be paid."

Public Health Service survey reports were used by FCDA in processing the applications submitted by communities for reimbursement under Public Law 875. About August 28 word was received that Army engineers had been instructed to move into the flooded areas and to award contracts for rehabilitation work.

Survey work continued as before, with the Public Health Service turning over its reports

to the Army Corps of Engineers. Consultation with the corps, relative to the protection of public health, produced gratifying results. One Army coordinator observed that a Service representative should advise every Army area on public health measures.

Much of the work involved supervision of the proper disposal of garbage and refuse, spoiled meats and foods, and other putrescible matter. Prolific fly breeding was found in many places. It was feared that the rat populations would increase in dump areas if some control were not exercised. Some of the dumps were visited by as many as 1,000 trucks a day, hauling spoiled foodstuffs and other debris. Arrangements were made to have bulldozers cover the debris, and, when this was impossible, to have the material sprayed with DDT. Malathion was used on flies reported to be resistant to DDT. Rat control measures were taken in some areas.

Approximately 1 square mile in downtown Woonsocket, R. I., was badly damaged by floodwaters of the Mill and Blackstone Rivers. Debris and mud settled heavily in the section, an area occupied by about one-tenth of the population of Woonsocket, or approximately 4,000 to 5,000 people. The tenement-type structures in the heavily populated section often had stores on the first floor.

A Service engineer detailed to the Rhode Island State Health Department was assigned to direct the disposal of all wastes in the damaged area of Woonsocket. Because the space for disposal was limited, combustible material was separated from organic material and then burned—flame throwers were used to start the burning of wet combustible material. Organic material was dumped in landfills. In all, 45,000 cubic yards of refuse was burned, and 2,300 cubic yards was covered with earth.

In Waterbury, Conn., Service personnel assisted in the cleaning and decontamination of flooded restaurants and bars. Their work soon extended to barber shops, soft-drink bottling companies, meat-packing plants, and railroad freight-cars. Washing and chlorine rinse were considered adequate in most cases. Disinfection by gas was recommended where necessary and practicable. Laundering or dry cleaning was suggested for linens and upholstery.

Health Activities to Combat Flood Damage

—Bucks County, Pa., Experience—

By MELVINA F. PALMER, R.N., M.P.H.

DURING and for several weeks after the flood caused by Hurricane Diane on August 19, 1955, the Bucks County (Pa.) Department of Health served in four general ways: coordination and direction, sanitation services, antityphoid inoculations, and other medical and nursing services including health education.

The county health director, as medical coordinator of the Bucks County Civil Defense Organization, acted as the medical adviser during the declared state of emergency. He directed and coordinated the health activities of the county, working with many local groups and agencies as well as with several national disaster relief groups. He also cooperated with the regional flood headquarters of the Pennsylvania State Health Department, temporarily established at Easton.

It is difficult to convey the meaning of "directed and coordinated" health activities during such an emergency, which affected the full length of the county bordering the Delaware River and the extensive lowlands along the snakelike path of Neshaminy Creek. It meant working around the clock for days, with the barest minimum of sleep and personally reviewing the flooded areas with civil defense and United States Army engineering groups. It meant keeping constant contact with local officials and being at the receiving and calling end of the telephone and short wave radio for

information upon which to base decisions, to answer multitudinous questions, and to give directions.

It included hauling typhoid vaccine and providing tetanus antitoxin and other biologicals requested for the protection of hundreds of flood relief workers exposed to injury and negotiating for school buses to transport child evacuees from the Delaware Island camps to their homes instead of to an evacuation center as first proposed. (This same evacuation center was commandeered only a few hours later for an entire flooded town.) It meant coordinating health activities in the face of hysteria and establishing and maintaining an intramural communications system so that the staff could be quickly mobilized for work in areas of acute need. For example, there was the setting up of nursing services in the evacuation center in the high school at New Hope and the setting up and running of 2 typhoid vaccine clinics on Sunday night in 2 firehouses because of the demands of frightened people.

Demands upon the energy, tact, and technical skill exercised by the entire staff did not cease when the water subsided. Instead, the demands increased in diversity and magnitude. It was well into October before the normal activities of some phases of the health department program could be resumed.

Sanitation

The debris laden waters of the Delaware and the Neshaminy caused widespread health hazards in the affected areas. Chief among these

Miss Palmer is director of public health nursing, Bucks County Department of Health, Pennsylvania.

In general, officers returning from flood duty felt that local, part-time health departments lack the facilities, personnel, and funds to cope with emergencies. Their reports revealed that full-time health departments are far better equipped and have the trained personnel needed for these situations; that lessons learned over the years relative to the germ theory of disease may result in the condemnation and waste of large quantities of slightly soiled but salvageable articles; that trained public health personnel, properly organized and deployed, will produce manifold dividends in a crisis; that there is need for carefully developed plans for disaster-aid operations in which administrative lines and duties are well defined; and that close organization is needed at the top of any emergency service.

Nothing can substitute for training and experience in an emergency of this proportion.

Close and friendly cooperation between the Public Health Service, the State departments of health, the Army Corps of Engineers, the Federal Civil Defense Administration, and the American National Red Cross emphasized methods for producing results by the teamwork that was shown. Public Health Service personnel were highly complimentary of the manner in which these organizations carried out their responsibilities. There were, naturally, many misunderstandings, particularly during the initial phases of the operation, but these were ironed out as time went on and as understanding increased. These "growing pains" should serve as lessons, and the knowledge gained therefrom should be used to guide operations in future emergencies of this kind.

Insured Group Medical Care

A detailed picture of the 174 plans using group practice in providing their membership with benefits is described in a report entitled "Group Practice Prepayment Plans: 1954 Survey," by Agnes Brewster, Division of Research and Statistics, Social Security Administration, appearing in the June issue of the *Social Security Bulletin* (vol. 19, pp. 3-11). A general account of all independent medical care and hospitalization plans made by the Social Security Administration in 1954 appeared in the April 1955 *Bulletin*.

Sponsored by consumer groups, unions, fraternal organizations, employer and employee associations, and physicians, these benefit plans give coverage to 3 million members located in 34 States and the District of Columbia. Differences in the plans range from diagnostic services only to the full range of physicians' and specialists' services and hospitalization.

The article delineates the benefits of the plans, together with the methods of financing them. Included are widely or infrequently used physicians' services, obstetricians' and surgeons' services, routine laboratory and X-ray examinations and treatment by X-ray, basal metabolism tests, electrocardiograms, physiotherapy, appliances, extent of provision of ambulance services, and inclusion of pharmacies.

Some plans are fully prepaid; others made extra charges at the time of receipt of services, and still others are at cost.

The various methods used by the group practice plans in providing hospital care include ownership of hospital, contracting with hospitals in the community, cash indemnity benefits, and arrangements with Blue Cross or insurance companies completely separate from the plan. Days of hospital benefit range from 30 to 365.

Flood destruction leaves in its wake silt, seepage, and possible contamination of all water supplies. The Public Health Service supplied 2,000 membrane filter packets containing equipment for testing and sterilizing well water in a New England area.

with the typhoid inoculations. They had already established a pattern of teamwork in mass inoculations through their experience in the spring and summer with the Salk vaccine program.

Associated with the inoculation program was the unromantic task of preparing registration cards and the seemingly endless job of alphabetizing and sorting. Many volunteers and employees worked day and night to keep this important aspect of the inoculation program flowing smoothly at the 45 clinic sessions. In the county office there is a register which lists most persons who received inoculations.

Health Education

A fourth area of service provided by the county health department was the provision of public health information for residents and physicians. Four telephones, two in addition to those regularly provided, were in constant use for days. In addition, short wave radio from the civil defense office was used for sending important messages. Telephone queries related to water, sewage disposal, typhoid inoculations, as well as a multitude of health and sanitation problems. A physician, an epidemiologist from the Public Health Service, came in for a few days to help relieve profes-

was the contamination of basic food and water supplies. The Bucks County Department of Health prepared and distributed information on practical ways of re-establishing safe water and food supplies and of disposing of spoiled and contaminated items. The three sanitarians devoted much of their time for many weeks to testing samples from private and community wells in the flooded areas and to giving detailed

¹ The Bucks County Department of Health procured vaccine, provided registration cards, and assisted between and after clinics with registration and organizing of data. ² The first inoculations were started by such groups as the Lady Garment Workers mobile unit, the Burholme and Trevoise rescue squads, and at Yardley, the Byberry medical staff.

instructions on decontamination. Approximately 800 samples were taken and tested by the 3 men. Technical advice was also given on the proper disposal of waste, the care of food, the disinfection of water-soaked buildings, the disposal of spoiled foods and dead animals, and insect and rodent control. An emergency courier service for daily transportation of water samples was provided by the

American Red Cross Motors Corps so that results of tests could be more quickly obtained.

Typhoid Inoculations

To prevent typhoid and to alleviate fear of the disease among large numbers of persons, the county health department participated in the administration and coordination of typhoid inoculations in 15 locations. A total of 44,025 inoculations were given. Only 40 percent of those receiving their first inoculations completed the series of three (see table).

The first clinics started on Sunday, August 21. Lights and sterilizers were run by emergency generators. The director, working quickly and closely with the several sources of supply, including the armed services, obtained the necessary vaccine. The syringes and needles, fortunately, were in adequate supply in the health department, having been obtained for the Bucks County cooperative Salk vaccine program. But equally important were teams of school and community nurses who assisted

Potable water is drawn from trucks located in key areas of Winsted, Conn. The Public Health Service assigned 45 technicians to stricken areas. Emergency field testing (bacteriological and chlorine residual) determined whether natural sources of water were safe or polluted.

Histoplasmosis Conference

By MICHAEL L. FURCOLOW, M.D.

DURING the 20th century, histoplasmosis has emerged from obscurity more rapidly, perhaps, than any other disease. Formerly known as a rare and fatal malady, it is now seen with great frequency, and estimates are that in the United States alone 30 million people have been or are now infected. More remarkable than late recognition of the disease, however, was the discovery that it is caused by a fungus, since the fungi were described and connected with disease half a century before the role of the smaller bacterial agents was discovered.

With the realization that this disease occurs frequently, its study has advanced on many fronts. Mycologists, serologists, epidemiologists, clinicians, pathologists, and even general biologists have contributed to this relatively recent accumulation of knowledge.

With knowledge advancing, it is obvious that some fields develop faster than others, and that knowledge and achievements in certain areas may not be generally available to all interested persons. With this thought in mind, the Communicable Disease Center of the Public Health Service in 1952 sponsored a histoplasmosis conference which was attended by 48 persons interested in the study of this disease. The purpose of the conference was "to take stock of our accomplishments and consider the possibilities of the future." Sixty papers were presented in five sessions. Fourteen papers dealt with clinical, epidemiological, and pathological aspects

Dr. Furcolow is chief, Kansas City Field Station, Communicable Disease Center, Public Health Service, Kansas City, Kans.

of histoplasmosis; 13 dealt with mycological aspects; 12, with serologic diagnosis; 9, with the skin test as an epidemiological tool; and 12, with natural reservoirs of the fungus.

Public Health

MONOGRAPH

No. 39

The accompanying discussion covers some of the findings presented in Public Health Monograph No. 39, published concurrently with this issue of Public Health Reports. The conference was sponsored by the Communicable Disease Center, Public Health Service, Atlanta, Ga.

Readers wishing the data in full may purchase copies of the monograph from the Superintendent of Documents, Government Printing Office, Washington 25, D. C. A limited number of free copies are available to official agencies and others directly concerned on specific request to the Public Inquiries Branch of the Public Health Service. Copies will be found also in the libraries of professional schools and of the major universities and in selected public libraries.

Proceedings of the Conference on Histoplasmosis held at Excelsior Springs, Mo., November 18-20, 1952. Public Health Monograph No. 39 (Public Health Service Publication No. 465). 319 pages. Illustrated. U. S. Government Printing Office, Washington, D. C., 1956. Price \$2.00.

sional persons in answering technical questions.

The county newspapers and commercial radio stations cooperated in the dissemination of information on the above subjects. This information (see below) was also mimeographed

and 30,000 copies were circulated in the flooded areas by Red Cross couriers, the health department staff, and civil defense workers, since few of the flood victims had regular channels of communication available to them.

HEALTH PRECAUTIONS FOR FLOODED AREAS

issued by

BUCKS COUNTY DEPARTMENT OF HEALTH

72 N. Main Street, Doylestown, Pa.

August 1955

Private water supplies—Boil all water 20 minutes before using. If you have no facilities for boiling water add $\frac{1}{4}$ teaspoon of household Clorox (10 drops) per gallon of water. Stir vigorously, let stand for 15 minutes. Fill glass half full of this water, cover with hand, shake, and smell palm of hand. If you can smell chlorine, water is all right. If no odor, add 10 more drops and repeat process. Zonite, H.T.H., Diver-sol, B.K., Pittchlor, or any other common household bleach can be used. Follow directions on container. Continue to use these instructions until you know your water supply has been made safe.

Wells—Open-top dug wells should not be disinfected because they are always dangerous and easily subject to reinfection.

Shallow driven wells should not be disinfected since they are dangerous and subject to pollution (shallow meaning up to 30 feet in depth). If the well was tested and found unsafe prior to the flood, disinfection will be of no value. If the well was tested and found safe prior to the flood the well can be disinfected and restored to its original good condition.

Method of disinfecting well—Wells of ordinary size may be disinfected by the following means: Empty one-third of the contents of a 1-pound can of chloride of lime into a metal or stoneware bucket. Add a small amount of water to this and stir, thoroughly breaking up all lumps until a smooth thin paste is obtained. Add from 1 to 2 gallons

of water to this paste and stir well. Allow to settle for a couple of minutes and empty contents into the well. It is not necessary to put all of the lime settling in the bottom of the bucket into the well. Add 2 more gallons of water to the remaining lime in the bucket; stir, allow to settle, and pour into the well. It is important that the disinfecting solution mix with the water in the bottom of the well.

Disinfecting homes, cellars—If chloride of lime is available, it is well to wash down all walls which have been flooded with a solution of chloride of lime. Wherever possible it is also well to whitewash all walls which have been subjected to flood waters. Cellars which remain damp and any other places which might indicate need may be sprinkled with hydrated lime.

Disinfecting home furnishings—All clothing, bedding, and other similar materials may be disinfected with chloride of lime solution or by boiling. The chloride of lime solution will act as a bleach on colored materials. Other materials which cannot be treated without injury with chloride of lime solution should be washed with soap and water and exposed to sun and air for several hours. In disinfecting by boiling, the actual boiling time should not be less than 20 minutes. In disinfecting with the chloride of lime solution, the article should be immersed or covered with the solution of strength so that the chloride odor is noticeable and kept immersed or covered for a period of 30 minutes before washing, rinsing, and drying.

Food for private consumption—All foods touched by flood waters, except canned goods, and all frozen foods which have lost refrigeration should be destroyed. Canned foods which have not been damaged are usually safe for consumption, but it is important that the outside of containers be sterilized before opening by dipping or washing container in chloride of lime solution, (not too strong) and then used only after having been thoroughly cooked.

Food for sale—The sale of foods damaged by flood waters is regulated by the bureau of foods and chemistry of the Pennsylvania Department of Agriculture.

To dispose of human waste—All washed-out privies and cesspools should be filled in. To make a temporary disposal unit, dig a trench 6 feet long and 1 foot wide. Place a blind around it. After each use cover the deposit with some earth. At the end of the day sprinkle it with chloride of lime.

Cover with earth. When the trench is nearly filled, stop using it; fill with dirt, mounded, and stamp firmly.

To dispose of garbage, spoiled food, or dead animals—Excavate a shallow pit about 2 feet deep. Use a bulldozer, if you have one. Dump in the material to be disposed of, almost to the ground surface. Compact it as best you can. Dig another pit beside it, and use this excavation to cover the first pit. Use at least 1 foot of dirt as cover. Burying refuse is better than trying to burn it, since it will be wet and will not burn.

Sampling Plan for a Small Household Survey

Whether older persons would enter the labor force, if they could, is a question with many complications. In a study conducted in Hagerstown, Md., the Division of Public Health Methods of the Public Health Service attempted to develop an interview to determine the degree of interest in working among older people and the extent to which poor health might be an obstacle to their employment.

This monograph deals with the sampling aspects of the study and presents in more than the usual detail the decisions that had to be made and the procedures finally followed in sampling for a household survey. The methods used in estimating sampling error from the survey results are also set forth. Subsequent papers will cover the evaluation of the interview schedule, analysis of scales of availability for work in the Hagerstown trial, and the illness among older persons in the city as revealed by the interview.

The requirements of the study which chiefly determined the sample design were: (a) the need for a probability sample of all persons 45 years of age and over, exclusive of those in resident institutions, living within the city limits of Hagerstown; (b) the need for a sample of sufficient size to permit the analysis that was contemplated; and (c) the undesirability of conducting more than one interview in any one household.

When we employ probability sampling we can say in advance how much sampling error we are willing to tolerate and then select the sample so that statistical conclusions about the characteristics of the whole population will not have a sampling error greater than the tolerable limits, except very rarely. Probability sampling requires that the probability of including any individual in the sample be known. In order to

accomplish this, it is necessary to have some sort of list of all the individuals, or of units including all of the individuals, in the population that is to be sampled. In Hagerstown, this list was supplied by the city directory and a city map.

Public Health

MONOGRAPH

No. 40

The accompanying summary covers the principal characteristics of the sampling plan for a small household survey described in Public Health Monograph No. 40, published concurrently with this issue of Public Health Reports. The author is a biostatistician with the Division of Public Health Methods, Public Health Service.

Readers wishing the data in full may purchase copies of the monograph from the Superintendent of Documents, Government Printing Office, Washington 25, D. C. A limited number of free copies are available to official agencies and others directly concerned on specific request to the Public Inquiries Branch of the Public Health Service. Copies will be found also in the libraries of professional schools and of the major universities and in selected public libraries.

Woolsey, Theodore D.: Sampling methods for a small household survey. Public Health Monograph No. 40 (Public Health Service Publication No. 480). 16 pages. Illustrated. U. S. Government Printing Office, Washington, D. C., 1956. Price 20 cents.

To preserve these papers in a single volume for future investigators, the proceedings of this conference are being published as Public Health Monograph No. 39, with a complete, up-to-date bibliography of nearly 800 references.

Here for the first time is summarized for the student most of the current knowledge of this intricate and interesting fungus disease. Here also are presented the baffling problems of the geographic localization of the disease and its apparent relationship to natural reservoirs of the fungus.

The clinical picture, with its variability from asymptomatic infection to bilateral chronic cavitory disease resembling tuberculosis, is also illustrated. The occurrence of epidemics is stressed. The usefulness of the skin test and serologic tests in diagnosis and epidemiological studies is reported. In addition to the difficulties of diagnosis, there are presented such public health problems as the prevention of a disease transmissible from nature rather than from other human or animal hosts, and the lack of adequate therapeutic measures. All of these things serve to point up one of the purposes of the conference, namely, to furnish guidelines for future research.

For the student of histoplasmosis, it is inter-

esting that the most important advances since the conference have dealt with the increasing awareness among clinicians of the prevalence of this disease. Especially is this true of chronic cavitory histoplasmosis as a problem in tuberculosis sanatoriums. In addition, advances have been made in pathological diagnosis by the use of special stains. An example is the Gridley stain, which has enabled pathologists to evaluate the frequency of histoplasmosis among patients undergoing surgery for suspected cancer of the lung. These refinements in pathological technique have supported the specificity of the skin tests reported during the conference.

Since the recognition of the prevalence of this fungus disease, there has been growing interest among clinicians and laboratory personnel in systemic fungus infections in human beings. This interest has resulted in increasing numbers of reports of infections with fungi previously considered rare or nonpathogenic.

In summary, it appears that this accumulation of knowledge of histoplasmosis may have many applications by public health workers, physicians, laboratory workers, and many others.

Advisory Committee on Indian Health

An Advisory Committee on Indian Health to assist in the improvement and expansion of medical care and health services to American Indians was appointed by the Public Health Service in May 1956.

The nine-member council will evaluate the Service's new Indian health program and assist in developing operating policies. They are N. B. Johnson, chief justice of the Supreme Court of Oklahoma; Anna Wauneka, chairman of the Navajo Tribal Council's Health Committee, Window Rock, Ariz.; Frank Ducheneaux, chairman of the Cheyenne River Sioux Tribal Council, S. Dak.; and Robert B. Atwood, editor and publisher of the *Anchorage Daily Times*, Anchorage, Alaska.

Also on the committee are Dr. Robert Neff Barr, secretary and executive officer of the Minnesota State Board of Health, Minneapolis; Dr. Fred T. Foard, director of the division of epidemiology, North Carolina State Board of Health, Raleigh; Dr. Alexander H. Leighton, professor of psychology, School of Industrial and Labor Relations, Cornell University, N. Y.; Dr. James Perkins, director of the National Tuberculosis Association, New York, N. Y.; and Dr. Raymond F. Peterson of Butte, Mont.

obtained as well as certain information about the demographic characteristics and labor force status of each person.

When the household contained only one member 45 years of age or older, all the questions on health and availability for work were addressed to this person. When there was more than one such member, the interviewer was provided with a sampling table which specified which member was to be interviewed in that household. Thus, in households with two persons in the 45-years-or-over class one of the two was selected at random, in households with three such persons one of the three was selected, and so on. In analyzing the results, it was necessary to restore the balance in this sampling by weighting each interview by the number of persons in the household who were in the age group of interest. This was done by reproducing the punchcard that was prepared from the interview, as many times as necessary.

The monograph also presents statistics showing the degree of success which the interviewers

had in reaching the sample. Of the total of 1,114 households in which an initial interview was desired, the interviewers completed 1,093 (98 percent). Six hundred fifteen of the households in which an initial interview was completed were determined to have one or more persons 45 years of age or over. The main interview was sufficiently complete to be included in the study in 600 (98 percent) of these. The 600 households contained 1,030 persons 45 years of age or older, but, as has been stated earlier, only one such person in each household was interviewed.

The monograph completes the exposition of the sampling methods employed with an illustration of the method of estimating the sampling errors from the survey results. A table of standard errors for percentages is also presented.

The sampling methods used in the Hagerstown survey are believed to have a wide range of application where the investigative technique is the interview-survey of a population sample.

Institutes in the Care of Premature Infants

A series of institutes for physicians and nurses in the care of premature infants is scheduled for the 1956-57 year at the New York Hospital-Cornell Medical Center. These institutes, which have been held each year since 1949-50, are sponsored by the New York State Department of Health and the United States Children's Bureau. They are designed for physicians and nurses in charge of hospital premature nurseries and special premature centers and for medical nursing directors and consultants in State and local premature programs.

Institutes are scheduled to begin September 17, 1956, November 5, 1956, and January 14, 1957. If the number of applicants is sufficient to warrant them, fourth and fifth institutes will be held beginning March 11, 1957, and early in May 1957.

Attendance at each institute is limited to 6 physician-nurse teams. The program for physicians lasts 2 weeks, and that for nurses, 4 weeks. Participants pay no tuition, and stipends are provided to help cover expenses during attendance. Early application is essential since plans are contingent on the number of applicants.

Additional information may be obtained by writing Box 143, Institute in the Care of Premature Infants, The New York Hospital, 525 East 68th Street, New York 21, N. Y.

The bulk of the sample was obtained by selecting what is known as a systematic sample of addresses from the directory.

Since directories are out of date as soon as they are issued, it was known that the sampling from the directory would have to be supplemented to allow a chance for households living at addresses not listed in the directory to come into the sample. This was managed by selecting a sample of blocks from a listing of all city blocks made up from a map of the city. Each block falling into the sample was canvassed, and all addresses were carefully checked against the directory. Any address in one of these sample blocks that was not listed in the directory was included in the sample. Finally, one area of the city where there had been a substantial amount of new construction was treated separately. All addresses in this area were listed and a sample was drawn.

Thus, the probability sample was carried out by dividing the addresses in the city into three strata: directory addresses, unlisted addresses scattered throughout the city, and unlisted addresses concentrated in new construction areas. An account is given in the monograph of the sampling in each of these three strata. Some unexpected obstacles were encountered, and the method of overcoming these is described.

The objective of obtaining a sample of sufficient size to support the desired analysis was achieved partly by guesswork and partly by providing a safeguard in case the guesswork was poor.

It had been decided, for reasons that will be presented later, that only one person 45 years of age or over could be interviewed in each household. The question was: In what proportion of the Hagerstown households would one or more persons who were past the 45th birthday be found? There were no available statistics on this point, but a guess was made that this proportion would be 50 percent. Since 500 completed interviews were thought to be a minimum number necessary for the analysis, it appeared that a sample of 1,000 households would be required to produce 500 households containing one or more persons 45 years of age or older. As a safeguard, however, it was decided that three separate samples of 500 households each should be selected. After the interviewing in

each sample had been completed, it would be possible by hand tally methods to determine not only how many completed interviews were available but also how large some of the frequencies that were important for the analysis would be. If a larger sample appeared to be needed, it was merely necessary to proceed with the interviewing of an additional sample of 500 households.

The population of Hagerstown in the 1950 census was 36,260; the number of households, approximately 11,400. To make allowance for inability to interview some persons, a sampling ratio of 1 in 21 for each of the three samples was decided upon. This ratio could be expected to provide 540 or more households in each sample. As it turned out, 56 percent of the households contained one or more persons 45 years of age or older. Consequently, it was found possible to stop the interviewing after the completion of the second sample.

Many of the questions in the interview were of a type that could be answered properly only by the person whom the question concerned. In other words, a proxy respondent could not be accepted. It was believed, however, that, if more than one person 45 years of age or older were to be interviewed in any one household, the replies of the later respondents would be influenced by overhearing the earlier interviews. It was, therefore, a requirement of the study design that a single respondent 45 years of age or over be selected from among those in this age group in the household. Furthermore, in order to meet the probability sample requirement mentioned earlier, the single respondent must be selected in such a way that the probability of any given individual coming into the sample could be known. In other words, the interviewer must be allowed no freedom in the selection of a respondent from among those 45 years of age or over who were found in the household.

This was accomplished by providing for opening questions to be addressed to any adult who could answer for the household as a whole. The first of these questions (which followed a brief introduction) was designed to find out whether there was anyone in the household who had passed the 45th birthday. If there was not, the interview was terminated. If there was, a complete roster of the members of the household was

supervised use of rauwolfia preparations in persons with essential hypertension.

Effect on Mental Hospital Populations

Because of the magnitude of the problem of the hospitalized mentally ill, hospital administrators and public health, welfare, and other governmental officials are interested in finding some way either to reduce first admission rates to these hospitals, to effect a higher turnover of patients, or to keep readmission rates low and thus eventually to decrease the size of the resident populations. The tranquilizing drugs possess some of the necessary properties of an agent that could achieve such results. However, much more information is needed about the processes in society that lead to hospitalization and about the factors in the hospital and in the community that lead to release before any major portion of observed differences can be attributed to the tranquilizing drugs.

Effect on First Admission Rates

Data show that between 1940 and 1950 there had already been striking variations—and, in several instances, reductions—in age-specific first admission rates to State mental hospital systems. It is emphasized that there is a need for much careful epidemiological and social science research to illuminate the facts about “paths to the mental hospital” as well as “the barriers” hospital administrators place between the hospital and the community before one can determine what part the tranquilizing drugs may be playing in the reduction of admissions to mental hospitals.

Effect on Release Rates

Data are presented to emphasize the complexities in interpreting release rates from mental hospitals and also to demonstrate that even prior to the advent of the tranquilizing drugs there had been striking changes in these rates. Questions are raised as to whether increases in release rates that have been occurring over the years are due to (a) more intensive use of various psychiatric therapies, (b) differences in the kind of risk being admitted now as compared to years ago, (c) changes in attitude of staff toward level of improvement expected in

patients prior to release, (d) administrative factors and staff and patient organization within the hospital, or (e) changes in the community's attitude and that of the patient's family toward the mental hospital and the mentally ill.

Because of the large number of variables, well-designed experimental studies are necessary to evaluate therapies singly and in combination with each other and with various ancillary programs. In such studies there must be carefully defined diagnostic groups of patients, appropriate control groups, carefully specified therapeutic plans and staffing patterns, and specific objective criteria for evaluating results of treatment and for determining condition at time of release. The questions about the importance of the tranquilizing drugs on the outcome of treatment emphasize quite sharply the need for clarification of what constitutes psychiatric treatment, and as to what are the objectives of treatment within the hospital setting. If hypotheses with respect to the effectiveness of the tranquilizing drugs in accomplishing the goals of hospital treatment are to be tested, then it is essential that experiments and studies be devised that permit comparison of the effectiveness of a treatment method without use of the drugs with its effectiveness when the drugs are used.

Implications for Staffing Patterns

Not only have the numbers of personnel in mental hospitals been inadequate in relation to the number of patients but the turnover of personnel has also been relatively high. The milieu now made possible in the wards of mental hospitals following the introduction of the tranquilizing agents, namely, a marked reduction in or elimination of motor excitement in patients and in the reduction or elimination of the use of seclusion and restraint, raises serious questions about how existing staffs will have to be retrained and how staffing patterns should be changed, as well as how many additional or fewer personnel will be required.

Followup Studies

The need for carefully designed followup studies is urgent to determine the relationship of

Problems in the Use of Tranquilizing Drugs

The tranquilizing drugs, such as chlorpromazine and reserpine, have been heralded as opening a new era in psychiatry.

Although these drugs may have such a potential, many facts are needed to assess the public health and social consequences that may arise from their widespread use. This monograph points to and discusses some major problems posed by availability of these drugs to the psychiatric profession and other branches of medical practice and the types of research needed to assess the effects of these drugs, particularly on mental hospital and outpatient psychiatric practice.

The tranquilizing drugs are being used on persons of all ages to treat not only a wide spectrum of psychiatric disorders but also hypertensive vascular disease and many other conditions. Their significant action is their ability to reduce motor activity, disturbed behavior, tension, and anxiety without producing sleep. The tranquilizing effect has been reported to be of value in the treatment of hospitalized psychotics by diminishing disturbed behavior without preventing patients from continuing to take part in psychotherapy, occupational, recreational and other forms of therapy. However, much research is needed to determine the immediate and long-range effect of the drugs both in psychiatric and nonpsychiatric patients. It is also necessary to establish appropriate dosages in relation to the various characteristics of the patient, such as age, sex, diagnosis, duration of illness, or general physical state.

Because of the tranquilizing properties of the drugs, information is needed on their psychological effects and the characteristics of the individuals in whom these effects are likely to occur. In this connection, the results of several recent studies show a significant incidence of severe depression, with suicidal tendencies in some in-

stances, in persons being treated for hypertensive vascular disease with reserpine and other rauwolfia products. This constitutes a major contraindication to the indiscriminate and un-

Problems in the Use of

MONOGRAPH

No. 41

The accompanying note summarizes the principal points discussed in Public Health Monograph No. 41, published concurrently with this issue of Public Health Reports. The author is chief of the Biometrics Branch of the National Institute of Mental Health, National Institutes of Health, Public Health Service.

Readers wishing the data in full may purchase copies of the monograph from the Superintendent of Documents, Government Printing Office, Washington 25, D. C. A limited number of free copies are available to official agencies and others directly concerned on specific request to the Public Inquiries Branch of the Public Health Service. Copies will be found also in the libraries of professional schools and of the major universities and in selected public libraries.

Kramer, Morton: Public health and social problems in the use of the tranquilizing drugs. Public Health Monograph No. 41 (Public Health Service Publication No. 486). 32 pages. Illustrated. U. S. Government Printing Office, Washington, D. C., 1956.

Cooperation Between Departments of Health and Welfare

By JONAS N. MULLER, M.D., M.P.H, and PEARL BIERMAN, M.A.

IN 1952 the Joint Committee on Medical Care of the American Public Health and Public Welfare Associations posed the thesis that the interests and practices of public health and public welfare were bringing the agencies concerned closer together(1). This was not a new thesis but a restatement that was especially timely in the light of the Social Security Act amendments of 1950(2, 3). These amendments made possible federally matched direct payments to the providers of medical care for certain needy persons and established the Federal-State program of aid to the permanently and totally disabled.

During the past few years, through a field

survey in 8 States and 10 local areas, the APWA and the APHA have sought to determine what cooperative activities are conducted in some official health and welfare departments.

Method of the Study

The States and localities selected for study were among those in which we might expect to find an optimum potential for close working relationships between the departments. These were:

California: Alameda County, city and county of San Francisco, San Mateo County; Maryland: Carroll County; Massachusetts: city of Quincy; New Jersey: city of Newark and Essex County; New York: Ulster County; Oregon: city of Portland and Multnomah County; Washington: city of Seattle and King County; Wisconsin: Rock County and the cities of Janesville and Beloit.

In each State, we arranged meetings with personnel in the State health and welfare departments, and in at least one local area. Occasionally some State personnel accompanied us on local visits. The meetings were informal and frequently led into topics which heretofore had not been considered jointly by the health and welfare staffs.

The typical meeting found top representation from administration, medical social work staff from both departments, medical directors or consultants of the welfare departments, supervisors of public health nursing, and, espe-

Dr. Muller is professor and chairman, department of public health, preventive medicine, and industrial hygiene, New York Medical College, New York, N. Y. At the time of the study he was staff director, Subcommittee on Medical Care, Committee on Administrative Practice, American Public Health Association, New Haven, Conn. Miss Bierman is medical care consultant, American Public Welfare Association, Chicago, Ill.

This report is an adaptation of a paper presented by the authors at the 83d annual meeting of the American Public Health Association, November 17, 1955, and of a paper prepared and presented by Dr. Muller at the Biennial Round Table Conference, American Public Welfare Association, December 2, 1955.

diagnosis, sex, age, length of hospitalization, therapy, and the socioenvironmental factors encountered by patients in the extrahospital world to relapse or successful readjustment. The tranquilizing drugs add further complications. For example: How should dosage levels used in the hospital be modified up to time of release? When the patient is released, on what dosage should he be maintained, if any? What problems does the use of these drugs pose for the family? What information should the family be given? What resources in the community are needed to follow up these patients adequately so as to prevent serious complications from developing in the patient, to detect complications when they have developed, and to take appropriate steps to safeguard the patient, his family, and the community as well as to facilitate readjustment of the patient to the extrahospital world?

Effect on Outpatient Medical Practice

Uses of the tranquilizing drugs have suggested the possibility that relatively inexpensive

agents are available that will make it possible to treat many types of psychiatric disorders on an outpatient basis. It has also been suggested that these drugs may reduce the need for psychiatrists in isolated communities where the general practitioner can now treat some of the milder forms of mental disorders. However, the widespread use of these drugs in our current state of knowledge concerning their immediate and long-range effects might also produce conditions that could tax seriously the limited psychiatric resources of the Nation. Some of the possible problems that these drugs may create are considered in relation to the psychiatric manpower of the Nation and the availability of outpatient and other community psychiatric services. It is suggested that administrators of community mental health programs scrutinize carefully the current organization of psychiatric outpatient and inpatient services to determine how they must be modified and reorganized to meet the new demands that may be placed on them by the advent of the age of pharmacotherapy in the psychiatric disorders.

Advisory Council on Vocational Rehabilitation

Mrs. Spencer Tracy, Russel W. Brothers, and Chester W. Haddan were appointed in May 1956 to 4-year terms on the National Advisory Council on Vocational Rehabilitation.

The 12-member council reviews applications submitted by private, nonprofit, or public organizations seeking Federal funds for partial support of research and demonstration projects or of special facilities concerned with vocational rehabilitation problems of nationwide significance.

Mrs. Tracy, president and director of the John Tracy Clinic of Los Angeles, has had long experience with problems of the deaf and hard of hearing. She has been associated with many organizations working on behalf of the handicapped and is the author

of numerous articles dealing with hearing impairments.

Mr. Brothers, secretary and treasurer of the M. P. Brothers Co., of Nashville, Tenn., is chairman of the Tennessee Governor's Committee on Employment of the Physically Handicapped and has long taken an active interest in the Tennessee vocational rehabilitation program.

Mr. Haddan, a specialist in the artificial limb field, is president of the Gaines Orthopedic Appliances Co. of Denver, Colo. He is also a member of the prosthetics research board of the National Research Council, the committee on artificial limbs of the American Medical Association's council on physical medicine, and the Colorado Governor's Committee on Employment of the Physically Handicapped.

and may soon be as acute in other welfare programs, such as services for the aged.

Welfare departments are acquiring medical administrative machinery, knowledge, and skill. They have long been concerned with long-term illness and disability and with the aged. Services for unmarried mothers, for dependent and foster children, for the aged, and for the prevention of delinquency all involve extended health responsibilities. The alert health officer is interested in all these areas and will help the welfare department find efficient methods of providing the required services. The cooperative efforts of health and welfare agencies will improve the health of the entire community.

Public Health Nursing

Public health nursing services are the most widely used of the health department services available to clients of public welfare agencies. Extensive field relationships between caseworkers and public health nurses, for the most part, appear to revolve around episodes or cases. These relationships are generally informal and unplanned, often the result of an accidental joint visit to a household. In only 1 of 8 States was there evidence of State policy directed at promoting such relationships except in the limited field of institutional inspection. This lack of definition of responsibility generally applies to local agencies as well.

In a number of communities, however, the services of public health nurses have been made available systematically to people served also by the public welfare agency. In Ulster County, N. Y., nurses from the county health department provide bedside care, including injection of medications, as an extension of the teaching program, for welfare clients who are homebound. Staff nurses obtain information concerning the family and home from the welfare caseworker. Case conferences are organized by field workers of the two departments on the initiative of either staff. Informal conferences, apparently more common, also are reported in the regular work sheets.

Some nursing services also are available at local nursing stations and at health department headquarters. The increasing caseload among the aged has increased the bedside care func-

tions of the nurse although the number of patients is not great. Staff representatives of the health and welfare departments have met to consider methods of meeting the need for home nursing service without disrupting the public health nursing program.

The Ulster County public health nurses bring advice on nutrition to welfare families. Nutrition consultation from the State health department thus serves the local welfare agency indirectly. Public health nurses also survey health care of children in foster homes.

This county has a well-developed orientation and inservice training program for staff nurses which draws upon the welfare staff. Much of the teaching is carried out in case conferences which involve all of the community agencies related to the particular case. At the time of our visit, there was no such use of health department personnel in the public welfare agency.

Services for Children

State public health personnel participate actively in both administrative and clinical services for child welfare. Standards for child care facilities and programs of all types are often developed jointly. In several States, the maternal and child health division of the health department provides medical administrative and clinical consultation to the division responsible for child welfare in the welfare agency. In Maryland, a good deal of time has been spent on how, and by whom, health supervision should be provided in foster care and adoption programs. In Wisconsin, requests for consultation have been limited to problem cases, but the board of health participated in establishing the standards for medical care in the foster home program, as well as the standards used by the division for children and youth of the department of public welfare in licensing children's institutions and day care centers.

Locally, the health department is likely to be engaged only in direct clinical services—child health conferences, crippled children's services, and, to a lesser extent, child guidance clinics. Occasionally these services are operated jointly, and the crippled children's services may be under the local welfare department. Relation-

cially from the welfare department, staff responsible for development of policy and standards. In one area, only two administrators appeared. At the other end of the scale, the chiefs of practically all operating units in both departments met with us.

Open-ended, but directed, questioning was used. Each agency was first asked to describe its overall program, with particular attention to the provision of health services to needy persons. Questions were then directed at relationships in regard to referral of patients, exchange of information, followups, and continuity of service. An attempt was made to call for illustrations of specific problems such as services to tuberculosis patients and to their families; preventive services to mothers and children; the determination of incapacity in aid to dependent children and aid to the permanently and totally disabled and the application of preventive and rehabilitative services once such a determination was made. Case histories often were used to illustrate relationships or the lack thereof, particularly by the local agencies.

This more or less clinical approach was followed by questions designed to bring out interdepartmental relationships arising out of service responsibilities. Since this was generally the most successful method of achieving information, the present report is organized under service titles.

In the preparation of this report, we have drawn upon the meager literature on health and welfare department relationships and also upon the knowledge of agency operations gained in work with such departments.

Patterns of Cooperation

There are many patterns of cooperation between health and welfare agencies which differ in form and degree. Most of them relate to activities somewhat remote from the recipient of service, and few are vigorously directed at the prime goals of health. Moreover, cooperation is practiced relatively seldom and is rarely explicitly defined as policy.

This is not to say that there is noncooperation between health and welfare staffs. There is often simply no relationship on the adminis-

trative level. In this connection, Dr. Palmer Dearing, Deputy Surgeon General, Public Health Service, said before the Conference of State Public Welfare Directors in 1950:

"It is conceivable that an effective program might be developed without any formal provisions for cooperation." However, he went on hopefully to say that, "if health and welfare staffs work closely and congenially together and consult spontaneously whenever they deal with interrelated problems, they will inevitably make plans together and define areas of responsibility . . ." (2).

Unfortunately, we have found that many health officers specifically avoid the responsibilities arising out of the fact that disease is most prevalent among persons known to welfare agencies. We were told frequently that the health department feared being labeled as an agency for the indigent if it made any special provisions for health services to the needy.

Public welfare departments—dedicated to the prevention of abnormal dependency and to the achievement and maintenance of normal, secure, and productive social living—have the same objectives as public health agencies.

To help clients realize these goals, the welfare department will require professional help in the administration of a medical care program. The definition of medical care is a broad one and includes many of the personal health services which may be provided by or through the health department (1).

"Medical care is essential for individual well-being. Its objectives include the promotion of health, the prevention of disease and disability, the cure or mitigation of disease, and the rehabilitation of the patient. Medical care for needy as well as other persons must be geared not only to treatment of disease but also to preventing its occurrence or progress. For those needy persons who are already disabled, all possible use should be made of rehabilitation services so that individuals may be restored to productive living, may cease to require the continued services of other members of the family, and may be enabled to live as useful and happy lives as possible within the limitations of their disabilities."

If preventive services are not known to the welfare program, if they are difficult to obtain, or even refused, then the welfare department will have to establish them. This need has been acute for some time in regard to child welfare

control programs for fiscal years 1954 and 1955 (7) notes as one of the continuing administrative problems "lack of coordination of program activities among all interested State and local agencies."

Cooperation in disease control by State agencies was not evident during our visits. One agency head feared that any notification to welfare clients of the availability of preventive services could be considered coercion and therefore was not an appropriate public assistance activity. A welfare client, he thought, should have the normal opportunity to find out that a chest X-ray survey was due in his neighborhood and any action by the public assistance agency concerning the survey might make the client feel that he had to have an X-ray.

In Wisconsin, however, where the State anti-tuberculosis association and the State board of health cooperate in sending mobile X-ray units around the State, each county welfare department is informed, through the State welfare department, when the unit is coming. All possible channels are used to encourage county agency clients to use the service. The latest tuberculosis control report of the Wisconsin State Board of Health notes that nursing homes are receiving special attention. Oregon also

reported special efforts in regard to nursing homes with indigent residents. In this State, representatives of both State boards confer to arrange care for tuberculosis patients.

We found that few local health departments have encouraged the welfare departments to give new clients a chest X-ray. A somewhat larger number of departments, State and local, notify local welfare agencies of chest survey schedules and help them achieve a high level of client participation. A few health departments have conducted campaigns to find tuberculosis among residents of nursing homes, homes for the aged, and lodging houses for single men. Health departments not infrequently provide X-ray facilities, as well as tests for syphilis, for screening possible foster parents or operators of child care facilities. Routine health examinations for personnel of other care facilities, or for health or welfare department staffs are relatively rare.

After diagnosis, coordinated services are needed to help a patient to recover. The patient and his family need to understand the disease and the treatment program. The patient requires knowledge of his family's status and assurance that they will not be neglected. With the patient under hospital care, there

Facilities for Research in Health Related Sciences

The Health Research Facilities Act of 1956, signed by President Eisenhower on July 30, 1956, authorizes the appropriation of funds not to exceed \$30 million for each of 3 years to assist in financing the construction of facilities for research in the sciences related to health. The act defines these sciences as including medicine, osteopathy, dentistry, and public health and the fundamental and applied sciences when related thereto.

Assistance will be in the form of grants-in-aid to public and nonprofit institutions. The Federal Government's share is limited to not more than 50 percent. Costs for the acquisition of land or off-site improvements and obligations made prior to the award of the research grant are not creditable for matching purposes.

The Congress has appropriated the first \$30 million to the Public Health Service. The funds are to be used, as the act specifies, in providing either or both (1) additional research facilities through the construction and equipping of new buildings or (2) the expansion, remodeling, alteration, and equipping of existing buildings.

A National Advisory Council on Health Research Facilities will establish policies and approve regulations for the administration of the new program. A grant-in-aid must have approval of the council before it can be awarded by the Surgeon General.

The Division of Research Grants, National Institutes of Health, Bethesda 14, Md., will supply application forms and any information requested.

ships are probably developed most extensively in the crippled children's program.

In many States, services for handicapped children engage both State health and welfare agencies, and sometimes, other State and local agencies as well. Primary State responsibility for the State-Federal program is in the health department in 32 States and Territories, in the welfare department in 8 States, and in a combined health and welfare agency in 1 State. In the remaining 11 of the 52 States and Territories reporting in 1954, the program is administered by special commissions (4 States), by departments of education (3 States), and in 4 States by the State medical schools (4). Where cooperation is practiced, relationships may extend to case finding, organized referral systems, case conferences, foster home placement, acceptance of responsibility for payment for care, the determination of eligibility, and clinical services.

In California, the State program of crippled children's services is administered by the health department, but in about half of the counties the welfare department has been assigned responsibility by the local board of supervisors. On request, consultation may be provided by either State agency whose field workers maintain an active relationship to determine the best ways of providing consultation.

In Massachusetts, the public assistance and child guardianship divisions of the department of public welfare have agreed to pay the costs of care for their clients when crippled children's service funds are lacking in the department of public health.

In New York State, case finding for the crippled children's program is an accepted responsibility of welfare workers, as well as of health department staff. As long-term custodial care for children who cannot be rehabilitated is difficult to locate, problem cases are discussed by staff members of both agencies. In practice, most of the relationships in New York's program are between the State health department and the local welfare departments. The active support of this relationship by State welfare department policy is important. The welfare departments aid in finding foster homes for handicapped children. For children who are not found eligible for the Medical Rehabilita-

tion Program (the crippled children's service in this State), welfare resources are occasionally called upon to provide services such as certain forms of orthodontic care.

In North Carolina, financial eligibility for care under the crippled children's program of the State board of health is determined by the State board of public welfare. This service, based upon a written agreement, is part of the State's policy of applying a uniform standard of eligibility for health services at State expense. In addition to investigation and certification of eligibility, the State board of public welfare agrees to assist with case finding, to provide transportation for patients to and from clinics and hospitals, to help in locating special equipment and services when crippled children's funds are limited, and to provide casework service to the patient and family in the adjustment to long-term treatment. These services are provided through the county welfare departments under instructions prepared by the State board of public welfare and reviewed by the crippled children's department of the State board of health (5). Similar agreements define the responsibilities of the board of public welfare in relation to the cancer program of the State board of health; tuberculosis sanatorium care provided by the North Carolina sanatoriums; correction of defects under the school health program of the board of public instruction.

Tuberculosis Control

The association between tuberculosis and economic deprivation calls for vigorous measures to prevent infection and to treat patients served by welfare agencies. In this area of communicable disease control, interdepartmental cooperation is highest, particularly between local agencies.

In their 1950 reports to the Public Health Service, 11 State welfare departments reported some type of tuberculosis control or hospitalization responsibility (6) although major responsibility rested with the State health department. It would be reasonable to expect some kind of relationship between these two State agencies concerning their responsibilities for certain tuberculosis control activities. Nevertheless, the annual report on State tuberculosis

cient knowledge to be an effective case-finding instrument for the noncommunicable chronic diseases.

Determination of Disability

Health department clinics in orthopedics, venereal disease, rheumatic fever, chest diseases, and cerebral palsy often help welfare departments determine a client's disability. The general medical services, including clinics, of about 70 local health departments across the country are the major or sole source of medical care for welfare patients in these areas. A few of these departments, such as the Baltimore City Health Department, have attempted to work toward the prevention of disease, especially chronic disease, by offering physical examinations. A few, such as the health department in Newark, N. J., have disability evaluation units. And here and there, a local health officer serves as medical member of the welfare department's review team for eligibility for aid to the disabled.

Rehabilitation

Aggressive concern with rehabilitation is a relatively recent development in welfare work (8), encouraged undoubtedly by the newest category of public assistance, aid to the permanently and totally disabled. Accompanying this new interest, however, is a certain feeling of frustration due, no doubt, to many long years of failure to obtain rehabilitation services for public welfare clients. Hence, a few welfare departments have developed their own rehabilitation programs (9).

For most departments, this choice is neither wise nor possible. It ignores the resources of the local health department for the development, application, and coordination of rehabilitation services. Certainly the public health staff can help welfare workers concerned with rehabilitation problems by interpreting the social meaning of medical findings and acquainting them with the medical aspects of rehabilitation.

There are a few places, however, where health departments have put their long experience with habilitation and rehabilitation of crippled children to effective use for all age groups. We know of only one State where this is policy:

Washington, where every local health officer serves as medical consultant to the district vocational rehabilitation counselor. Weekly meetings serve the day-to-day administrative needs of the vocational rehabilitation program. In addition, monthly conferences include any other local agency with an interest in a case on the agenda. The State health officer feels that this arrangement has been successful.

The California State Department of Public Health has been of help in the development of policies and procedures for improving opportunities for rehabilitation among the disabled parents of recipients of aid to needy children. The detailed story of the several interrelated projects involving the State department of social welfare, the bureau of vocational rehabilitation, and the department of public health is told in a series of publications (10-14).

Institutional Standards and Licensure

Probably the best developed cooperative relationships at State level revolve around institutions, particularly their licensing. Information obtained from 44 States in 1953 indicated that in 30 States the health department had legal responsibility for the program for all institutions serving older people (15). Six States assigned to the welfare department the accrediting program for all such institutions. And in eight States, responsibility was assigned to the health or welfare department according to the nature of the institution. The 1950 State health department reports to the Public Health Service indicate that, while health departments have major responsibility for licensing medical institutions in most of the States, welfare departments are responsible for most child care facilities in the States where there are licensing provisions; and in a few States, the welfare agency is responsible for the general or special hospital facilities (16).

Expert guidance, consultation, and field service from personnel skilled in health and social services are required if programs of licensure or other forms of accreditation are to be more than perfunctory. Both health and welfare agencies know that licensing can be a "tool" to achieve a higher level of care and service. General health care, rehabilitation, the prevention of

should be periodic reports to and from the community agencies concerned with the patient and his family. Case conferences to set rehabilitation goals and make appropriate pre-discharge plans smooth the path back to active life. When care on an ambulatory basis becomes possible from a clinical point of view, social, economic, and public health problems which stand in the way of such therapy must be solved by coordinated efforts.

The integrated service of a combined local department of health and welfare, as in San Mateo County, Calif., has pioneered in meeting the needs of patients with tuberculosis. This department is responsible for the county institutions as well as for the full range of public health and public welfare services.

The entire tuberculosis control program is under the medical director of the sanatorium, to assure continuity of service from case finding and diagnosis through followup. A full-time public health nurse at the sanatorium keeps liaison with the field staff. Problems relating to the treatment plan for a patient are usually worked out in the district by frequent and informal meetings between the public health nurses and caseworkers.

If difficulties require administrative consideration, the family is brought to the attention of the supervisors. Medical consultation is immediately at hand. The staff confers on patients under care twice each month. A representative of the social service division participates whether or not the patient receives public assistance.

Planning 2 to 3 months ahead in anticipation of discharge from the sanatorium applies to every public patient in San Mateo County. The sanatorium itself has a rehabilitation program in which a representative of the district office of the State bureau of vocational rehabilitation shares. Psychiatric services also are provided. Thanks in large part to the relationship established by the department in this program, an unusually low proportion of patients leave the sanatorium against medical advice.

Services for Chronically Ill and Disabled

In most communities, unfortunately, relationships in regard to chronic diseases and adult

rehabilitation are not strikingly different from relationships in regard to disease control, with a few possible exceptions.

Basic Studies for Program Development

In two States noted for their chronic disease programs, California and New York, departments share actively in basic studies for program development. New York State studies have been concerned with the extent of chronic illness and disability. In California, the director of the State department of social welfare served on the advisory committee for the chronic disease investigation conducted for the legislature in 1949 by the State department of public health. Welfare directors of 38 counties contributed their experience as well. Welfare officials contributed also to the 1954 health survey conducted by the chronic disease service of the State department of public health.

Mutual Support of Legislation

Cooperation on legislation, though somewhat rare, was noted in several States. Development of the Lemuel Shattuck Hospital in Boston, operated by the Massachusetts Department of Public Health, may be credited to the joint planning of the health and welfare departments and to their mutual assistance in preparing and supporting legislation required for its construction. This hospital for persons with chronic diseases is a base for both service and research.

Case Finding

Case finding is not widely practiced in welfare departments except in relation to communicable disease. For example, no State welfare department in 1950 reported to the Public Health Service responsibility for diabetes control (6); only 7 State welfare departments reported contributing to heart disease control; only 8 to cancer control. This listing, however, does not cover "unofficial" responsibilities. Massachusetts, for example, is not included although the State health department's 26 tumor clinics regularly refer to the welfare department cancer patients who require and are unable to afford long-term care.

While welfare departments do play a part in case finding for certain communicable diseases, most welfare staffs do not yet have suffi-

sultation to relate payments to services needed and received.

Day care centers for children, a responsibility of the Oregon Public Welfare Commission, must have standards certified by the board of health to be eligible for monthly State aid. Group care homes for mentally and physically handicapped youngsters, licensed by the board of health, must meet standards set in part by the public welfare commission.

In Maryland, an interdepartmental committee sets criteria for rates of payment by the welfare department for nursing home care. A similar joint committee, with representation from health, welfare, and education develops standards for the licensure of day care centers in Maryland.

In Massachusetts, day care facilities for chil-

dren, licensed by local health departments, use standards developed by a joint committee of the State departments of public health, public welfare, mental health, and education. Consultants of these departments are available to the local areas on request through the district offices of the State department of public health.

Illinois provides another "example of the way in which the health and welfare departments can work together to improve the service provided." The State department of public health, the licensing agency, sends to the public assistance agency copies of all letters to individuals operating or planning to establish nursing homes. This enables the State public assistance agency to exchange information with county welfare departments concerning nursing homes which have been or are about to be licensed.

Nine Grants for Hospital Research

Nine grants totaling \$367,182 for new research and demonstrations in hospital service and administration were announced in July by the Public Health Service of the Department of Health, Education, and Welfare.

The research is aimed toward improving the care of patients in hospitals and health facilities, reducing costs, and helping to make the benefits of hospital and health services more widely available.

The University of North Carolina School of Medicine, Chapel Hill, will study the referral of patients from rural areas to the outpatient clinic of the university hospital.

The University of Tennessee College of Medicine, Memphis, will demonstrate how a coordinated hospital plan for the entire State can be developed.

The University of Michigan, Ann Arbor, will initiate two projects: (1) A study of how the organization, staffing, and procedures in 20 Michigan hospitals are related to the type of care the patients need and receive, and (2) a study of the relationship of administrative and supervisory practices in hospitals, motivations and job satisfaction of the employees, and effectiveness of job performance and organization.

St. Louis University, St. Louis, Mo., will develop a program of graduate study in hospital administration at the doctorate level for advanced students to carry on research.

Columbia University School of Public Health and Administrative Medicine, New York City, will study the influence of different patterns of organizational and community relationships and of new hospital construction on the quality of medical, hospital, and related health services.

The Council of Jewish Federations and Welfare Funds, New York City, will study the coordination of the facilities of the general hospital with the resources of other medical and related community services.

The Minnesota Department of Health, Minneapolis, will initiate a project to demonstrate how the quality of service given patients in State hospitals can be improved through the development of methods for inservice training.

The American College of Physicians, Philadelphia, will study methods for minimum standards of quality and efficiency for evaluating the practice of internal medicine in hospitals.

secondary disability, accident prevention, the use of nursing, nutrition, and social services, all call for their joint attention.

Cooperative efforts range from contractual agreements to informal but regular visits by field personnel of the licensing agency to the local health or welfare office for exchange of information. Joint action may include:

- Definition and approval of standards.
- Assignment of responsibility for various aspects of the inspection and licensing program.
- Development of an educational program for the participating agencies, their local opposite numbers, and for the operators of facilities.
- Exchange of information relating to the licensed facilities.
- Coordinated efforts, when necessary, for enforcement of the licensing law and regulations.

These activities may be based on law or they may grow out of contractual agreements. In some places, the policy of each agency specifies working with other agencies to meet the responsibilities assigned by law or custom to one or the other agency. Most commonly, however, these joint activities, as do so many others, rest on the authority of custom.

One of the successful statutory requirements for sharing responsibility in an institutional licensing program is found in Kansas. "Adult boarding homes," which include proprietary skilled nursing, personal care, and simple shelter facilities, are licensed by the State department of social welfare. The law calls for the participation of the State board of health and the State fire marshal as well as county health and welfare departments and the local fire and safety authorities. Child care facilities are licensed by the State board of health in conjunction with State and local agencies indicated above. In each area, teams jointly inspect the homes. Their visits are supplemented by calls by individual team members to help the home administrator.

In Sedgwick County, interdepartmental meetings have grown out of the licensing program. At these meetings, boarding home management and care of their residents, and child welfare and child care facilities are discussed.

Even in this apparently well-planned development, however, a recent study of the attitudes of public health nurses in the adult boarding home program reveals complaints of overlapping responsibilities, difficulties with representatives of other agencies, slights to professional prestige, and administrative failure to heed their professional judgments. Nevertheless, this joint program has improved and increased agency services to recipients of public assistance and has certainly increased the quantity of preventive health services made directly available to these recipients (17, 18).

In California, a tripartite agreement on standards and licensure responsibilities is observed by the State departments of public health, social welfare, and mental hygiene in regard to sheltered care for older people. The agreement results from a policy of working together to define the tasks that arise from responsibilities assigned by law to one or another department; to outline the knowledge, technical skills, and contacts of each department which could help the assigned agency to meet its obligation; and to agree on the use of all of the appropriate resources. Actually, joint conferences in this State preceded the writing of the law, to assist the legislature in preparing the requisite legislation. Such conferences are a regular feature of interagency relations in the California State Government. Mutual support of legislative programs and budget requests, based on understanding and an appreciation of common interests, is a natural outgrowth of this policy.

Oregon also offers interesting examples of interdepartmental institutional services. The State board of health licenses nursing homes and periodically circulates a list of licensed homes to the State and local welfare departments, a service that is by no means common, however elementary. The field staff of the licensing division visits the county welfare offices to learn what the staff knows about care in local nursing homes. This productive relationship, although found in a number of States, is often overlooked even in States with well-developed relationships in other areas.

The criteria for rates of payment to nursing homes were developed by the Oregon Public Welfare Commission with board of health con-

There are several examples of cooperative action relating to the rates of payment to hospitals and related facilities, such as the joint committees for nursing homes in Oregon and Maryland mentioned above. Rates paid by the New Hampshire Department of Public Welfare also are based on a classification of nursing homes by the State board of health.

In two States, interdepartmental committees representing the major purchasers of general hospital care have agreed upon methods of establishing hospital payment rates. In Illinois, such a committee has operated successfully for the past 11 years (196). There the State department of public health, the public aid commission, the division of services for crippled children of the University of Illinois, and the State division of vocational rehabilitation use the same Technical Advisory Committee on the Purchase of Hospital Care. Members are hospital administrators representing the Illinois Hospital Association who meet periodically with representatives of the four participating agencies to advise on a cost formula and payment agreements. The State department of public health provides staff, collects and analyzes the cost reports, certifies the cost figures, and classifies the hospitals. Each agency then agrees to pay hospitals on the basis of the certified costs.

In New York State, a similar plan is coordinated by a Hospital Rate Advisory Committee with representatives from health, welfare, education, mental hygiene, and the executive departments. The bureau of research and statistics of the department of social welfare makes the necessary statistical computations and certifies rates to each agency.

Rates paid to hospitals in Massachusetts by the department of public welfare are based on a formula and procedures for cost analysis worked out by the department of health and the State hospital association. In Virginia, the State department of health reviews and certifies hospital cost analysis for the department of welfare and institutions and the division of vocational rehabilitation and advises on hospital administration and licensure.

Interdepartmental services related to institutions appear to demonstrate the only clear-cut and consistent collaborative use of the skills

of State health and welfare departments. But their potential for improvement of institutional services to people has barely been tested. Nor have they been used sufficiently to bring the resources of the two agencies together to consider other areas of mutual concern.

Consultation Outside Institutions

Consultation services are by no means restricted to the institutional setting. In the APHA study already mentioned, 123 local health departments (of 187 respondents) said that they provide consultation to the local welfare department. And 125 departments indicated that they receive consultative services from the welfare department. Only 34 health departments of 187 with some kind of active chronic disease program employ their own social workers. But another 123 departments use social work services obtained through some other agencies.

Asked whether the health department had knowledge of the welfare department policy on food expenditures, four health departments said that the information was not available from the local welfare department. Forty-one of the 187 health departments did not have the information.

In Quincy, Mass., on the other hand, the health department nutritionist has been an active participant in public welfare programs, assisting in training caseworkers and consulting on special diets. She has visited with caseworkers at homes where large families with small budgets need advice on food selection.

The bureau of nutrition of the New York State Department of Health, in addition to providing consultation to the State department of social welfare, has helped to bring together local public health nurses and caseworkers for education on food budgeting and nutrition. State nutritionists have also served as consultants to local interagency conferences of public health nurses, caseworkers, and casework supervisors concerned with specific families and their diet.

General Administrative Services

The California rehabilitation project mentioned earlier (14) was designed not only to

Observations of the public assistance visitor and of physicians who treat public assistance clients are transmitted to the health department. The two State agencies have cooperated, when indicated, in revoking or refusing a license. This close cooperative arrangement has helped to improve the quality of care in the commercial and other nursing homes in the State (19a).

Local departments of health usually have limited relationships with State institutional licensing programs whether they be administered by the State health, welfare, or other agency. The local department may serve as a source for a sanitarian. On the other hand, county welfare departments are often prime sources of information on nursing homes and similar facilities, even when the State licensing program is administered by the health department. Unfortunately, there is rarely a two-way flow of information to enable the local agencies to know what recommendations have been made to institutions, what disciplinary action is pending, or which facilities are currently approved.

New York provides a notable exception to this generalization. Here the State department of social welfare administers the "approval" program for nursing homes and in addition some county health departments license these institutions. To help maintain the positive direction of these parallel accrediting programs, a working agreement has been developed between the respective authorities.

The report of a recent APHA study of the chronic disease activities of selected local health departments states that 72 departments (of 187 selected for study) license institutions caring for persons with long-term illness or disability. Seventy-one said that they participated with other community agencies in establishing standards of care in these institutions. Few indicated a solitary role in standard-setting. The report will be presented at the annual meeting of the American Public Health Association in November 1956.

Nutrition Consultation

Nutrition consultation is a popular and useful institutional service which crosses depart-

mental lines (20). The APHA study reported that, of the departments selected, 70 offer such consultation to institutions caring for the chronically ill and disabled. Forty of these departments employ a professional nutritionist; the others presumably draw upon a State consultant or upon their public health nursing staff.

The Nassau County (New York) Health Department has a unique feature of teaching nutrition in a program directed generally at improvement of service in nursing homes. A local licensure provision assigns to the department responsibility for setting standards and licensing nursing homes. The consultant services of a nutritionist from the State department of public health are available to the local department and there has been some direct service to nursing homes from the State health department personnel. Medical consultation relating to diet is available within the county department. Results of the Nassau County program with respect to food practices, safety, and nursing care confirm the usefulness of this educational approach (21).

The Illinois Department of Public Health also maintains a nutrition consultation service in its licensing program (22). In Maryland and Wisconsin, nutrition consultation is offered not to institutions but to the welfare department staff concerned with standards and licensure for children's institutions.

Payment for Institutional Services

Although public agencies have a growing responsibility for payment for institutional services, no one of the agencies is likely to have a staff adequate to ascertain that the public monies are well spent for institutional care. In many States, each agency purchases such services separately, with resulting annoyances and inequities to the institutions, and duplication of effort. It is an unfortunately common practice to pay higher rates for the care of bed patients than for patients who get out of bed with or without aid. (We do not recommend decreases in such payments. Rather, in view of the generally low and unrealistic rates of payment to nursing homes, we would call for the eventual application of the principle of payments based on the costs of care.)

joint planning. Joint committees on nutrition, aging, adoptions, mental health, rehabilitation, and nursing homes are among the usual ones. Council committees on housing, on determination of medical indigency, and on medical care for the needy are not uncommon in communities engaged in evaluation of health and welfare services.

In addition to their technical consultation services, health department representatives may serve on the advisory committees of the public welfare program and on the board itself to encourage a preventive approach in both health and welfare programs.

Comparison of State and Local Relationships

Relationships between State health and welfare departments, whether established by law, contract, or verbal agreement, are more likely to be in the administrative area than in the area of direct service.

In local departments, direct service produces the greatest evidence of joint effort although, for the most part, cooperation is personal rather than official. This relationship could be broadened and made more effective by formal State and local policy.

Conclusion

Five years ago, former Surgeon General Leonard Scheele (3), speaking to the American Public Welfare Association, said:

At any gathering of health or welfare people, the need for a cooperative attack upon interrelated problems is likely to be discussed. Public health people talked about it extensively at the recent American Public Health Association meetings in St. Louis. There is an equal eagerness among social workers. Yet, after the meetings are over, a cold, analytical look at actual operations in local communities and throughout the Nation shows that the "trend" toward cooperation is painfully slow. From the standpoint of structure for cooperative action, these organizations seem to be almost as far apart as they were in the days when welfare meant an occasional coal or grocery order and when public health meant a red placard on the home of a scarlet fever patient.

Although our current report describes patterns of cooperation among our State health and welfare agencies, Dr. Scheele's statement

of 5 years ago still applies. It is our impression that we have yet to reach the following four goals of joint activity:

1. **Application of the normal program of the health department to the welfare population through active cooperation with welfare departments.**

It may be necessary to modify or extend services within the range of knowledge, skills, and budget of the health department in order to meet the health needs of the welfare population. Meeting these needs may, of course, result in establishing an effective program of disease prevention.

Since ill health and disability rank so high among the causes of dependency, there is a moral responsibility and, in many instances, a legal responsibility to make health services available to the population in need.

The role of the welfare department in achieving the full application of the program of the health department to the welfare population requires active encouragement of welfare clients to use health services, especially preventive services. Welfare agencies do not hesitate to offer advice on a family budget or the food content of the diet possible within that budget. The relationship between client and agency offers an equally good opportunity for advice on when and how to use health services.

2. **The development of appropriate health promotion and disease prevention activities in the welfare program itself.**

A major responsibility of the health officer and his staff is to aid the welfare staff in identifying and developing areas in the welfare program which can serve to promote, protect, and restore the health and social usefulness of the people who come to the department for help.

First and probably most important is intake. Intake offers the ideal opportunity to determine the health status and needs of the potential client. This is the chance, usually neglected, to make preventive health services available as well as to establish a medical plan for the person and family in need.

Once the welfare department has accepted the client for service, the avenues toward health services are many and the guide is usually the caseworker. The achievement of health by the

extend the use of rehabilitation services but also to demonstrate the advantages of regular medical consultation to the public welfare program, and to call the attention of local departments to one of the ways of obtaining consultant services. A contractual agreement between the State departments of public health and social welfare calls for the full-time assignment of a medical officer to the welfare department.

New York State also offers examples of effective sharing of professional personnel. A health department nutrition consultant prepared a special diet manual for the department of social welfare and is available for other services. A dental consultant is detailed from the health department to provide services on a part-time basis. And, in an instance that is still unique, a deputy commissioner of health has been assigned to the department of social welfare full time as director of medical care. He has ready access to the resources of both departments, attends staff meetings of both organizations, and acts as interpreter of the programs of both agencies. The background of public health administration has made itself manifest in the medical care program for the needy, notably in rehabilitation services, in nursing home care, and in physicians' services.

The State department of social welfare has vigorously supported requests of the health department for social work staff. It has helped to draw up standards for such staff and has invited health department medical social workers to participate in semiannual meetings of its own medical social workers. The medical social service chief has provided orientation sessions on the welfare program to the public health nurses of the department of public health.

Many State agencies fail to provide staff orientation in programs of related agencies, not to mention their own. Everyone appears to agree on the need for such orientation and most ruefully admit there has not been time to carry out adequate orientation in their own program.

Among devices for achieving knowledge of programs of other agencies is the joint committee, such as the New York State Interdepartmental Health Resources Board with representatives from the departments of education, health, mental hygiene, correction, labor, and

social welfare; the Workmen's Compensation Board; and the Joint Hospital Survey and Planning Commission. Committees of the board provide a machinery for joint planning, coordination, and consultation. Other interdepartmental bodies, not part of the State interdepartmental health council but with health and welfare participation, include advisory committees to the department of mental hygiene and to the State Youth Commission.

None of these bodies is simply a paper representation. All have been concerned with planning and consultation and with joint studies and legislation. The State plan for chronic disease and rehabilitation facilities was thus jointly developed, as was also the rehabilitation program for adult public assistance recipients at the rehabilitation hospital operated by the State health department.

Local services and activities affecting administration of both health and welfare departments have been mentioned above under program titles, such as the use of joint staff conferences concerning patients with tuberculosis, child care, or for the definition of rehabilitation objectives for a patient. Such conferences for the solution of clinical problems play an important part in administration per se. They are, in themselves, manifestations of administrative policy. Case conferences serve also to bring people and agencies together, to understand one another and to exchange ideas and information. Often, the conference results in the definition or clarification of broad policy.

A meeting of the Suffolk County (New York) Health and Welfare Department staffs, about 2 years ago, showed how multiple demonstration case conferences in a workshop setting help achieve "more efficient interagency referral and communication systems" (23) and more direct contact among staff members. As a result, a joint committee was formed to interpret each agency's progress "and to develop further techniques for a better understanding of each agency's program," with consequent increase and improvement in referrals to both agencies.

Joint committees and active membership in community councils of social agencies are familiar methods of approaching common problems. They may be used also as the setting for

4. The development of the necessary policy and procedures to achieve improved health and welfare services without duplication when several agencies are involved.

Many functions of welfare departments touch those of the health department. And "touch" is often about as far as the relationship goes. This is true particularly when institutional inspection and licensure are assigned the welfare department and the health department is assigned responsibility for the sanitation inspection. This latter function rarely extends beyond the determination of technical compliance with the law and its regulations. The standards of nursing home care appear to have been markedly improved, however, in those States and counties where health and welfare department cooperation has been consciously organized. Crippled children's services, the tuberculosis control program, and rehabilitation services for adults likewise are improved where there are mutual responsibilities.

Examples of cooperative activities directed toward this goal range from organized referral procedures and a policy of using interagency case conferences to written contracts for the provision of specified services under stated conditions and to mutual study of long-range needs and support of legislation.

When these objectives of joint activity are reached, efficient operation will be assured, and the potential for better service, where responsibility overlaps, will be recognized. Each agency will be sensitive to the needs, and aware of the resources, lying outside of its own area of service.

To date, in the words of former Surgeon General Parran (24): "... In the tremendous problem of providing [health services] for the indigent, the social welfare agencies have taken the lead, largely because health departments have been unwilling or unable to accept this as a direct responsibility. The situation, however, is somewhat analogous to the relation of the health officer to the public water supply. He must know the needs for an adequate supply of potable water. He champions the provision of such a supply. He sees to it that the water plant is properly operated, even though this may be done by another branch of the city govern-

ment. This is the minimum responsibility which the health department should assume, both for the public water supply and for the public medical service needed by those unable otherwise to provide it. In fact, the health department should be instigator of and friend to all useful activities for the conservation of life and health. For if health officers do not recognize their responsibility, using all the methods given us by science, to organize community attacks upon the causes of ill health, the public health profession will revert to the ancient status of sanitary police, and other public medical agencies will be established to deal with the major health problems of today and tomorrow. We may be sure such problems will be dealt with."

client, therefore, depends in large part upon the caseworker's alertness to the client's health needs and the worker's knowledge of the community's health resources. The welfare department needs the help of the health department in providing the orientation and knowledge necessary to create a high level of health interest among its staff. In our experience, welfare departments rarely call upon their health colleagues for such help.

Surely it is important for the caseworker who enters the client's home to be alert to the health status of the entire household; to try to ascertain what hazards to health arise out of the physical environment of the home and out of the social dynamics of the life within it. The translation of this knowledge into constructive family action implies health education, for which trained personnel of the health department should be able to offer knowledge, skills, and materials, as well as assistance through staff development programs in the welfare department.

In each of the categories of public assistance administered through the local welfare agency, there are opportunities for health department participation in identification of needs, in planning, in consultation, in the provision or coordination of services. Identifying and planning to meet rehabilitation needs of parents of recipients of aid to dependent children, tuberculosis screening for recipients of old age assistance, and consultation on problems among recipients of aid to the permanently and totally disabled are examples of services now provided in a few places by State and local public health departments.

As to general medical care, every welfare agency has one or more opportunities to tell its clients about services available and to encourage their intelligent use. There should also be opportunities to define the objectives of the medical care program to the providers of service and to assure that the program can function so as to achieve its objectives.

A positive approach to medical care, as distinguished from preoccupation with disease treatment, will emphasize prevention, early diagnosis, prompt treatment, and active rehabilitation. Such an approach will encourage appropriate use of the physician's services

rather than impress upon the client that "he must not seek the doctor's help unless he absolutely needs it." Health department representatives, serving among other members of a medical advisory committee, can help to develop and foster a positive approach to the medical care program.

In some instances, the health department's personnel and services may be all, or part, of the medical care program. Unfortunately, we have found that even when the health department is responsible for the general medical care program, a positive approach does not automatically ensue.

The current emphasis on extension of welfare department services beyond cash assistance implies a continuing increase in the health responsibilities of welfare agencies: services for unmarried mothers, for dependent and foster children, for the aged, and, in some communities, for families at large; and services directed at prevention of juvenile delinquency, control of alcoholism, or at the maintenance and improvement of standards of institutional care. In defining the objectives of these programs and in developing ways to attain their goals, welfare and health departments need to pool their knowledge. This is reason enough for getting together.

3. An increased awareness of the social and economic needs of persons coming to the attention of the health department and a clear understanding of the responsibilities, the potential activities, and the limitations of both agencies in support of people with such needs.

The welfare department has a right to expect that the health department is prepared to make referrals appropriate in content and time. Conversely, the health department has the right to expect appropriate referral for the services it offers. But this right is not fulfilled automatically. Public health nurses may have a hard time relinquishing part of their responsibility for patients, as caseworkers may for their clients. Successful referral programs provide administrative support and assurance through knowledge of personnel and operations, that the best interests of their patients or clients will be served by referral. Regular contact between the agencies concerned is needed to make this possible.

Apparently real geographic variations in mortality from coronary heart disease occur in the United States. Further study of the populations with high death rates and those with low death rates may provide new clues concerning the factors responsible for this disease.

Geographic Patterns in Deaths From Coronary Heart Disease

By PHILIP E. ENTERLINE, M.A., and WILLIAM H. STEWART, M.D.

CONDITIONS for 1950 are more favorable to a study of deaths from coronary heart disease in the United States than for any prior period.

A complete population enumeration, which is important for the computation of death rates, is available for that year. Moreover, the sixth revision of the International Lists of Diseases and Causes of Death, which became effective in 1949, provided a single category (420) under which deaths from coronary arteriosclerosis were to be counted. Also, under the sixth revision of the International Lists, the Manual of Joint Causes of Death was abandoned, and the physician signing the medical certificate of death was given the responsibility for designating the underlying cause of death, the cause used in primary statistical tabulations. (There are a few exceptions to this general rule, but they are favorable to the counting of coronary

heart disease in primary tabulations.) According to the joint cause manual, if a death certificate carried the diagnoses of nephritis and acute coronary thrombosis, for example, it was counted as a death from nephritis. Under the sixth revision, if the attending physician states that the underlying cause of death is acute coronary thrombosis (coronary heart disease), the death is counted as a coronary heart disease death. (The term "coronary heart disease" as used here is synonymous with the International List term "arteriosclerotic heart disease.")

Geographic Differences

The 1950 death rates for coronary heart disease in the United States present an interesting and thought-provoking geographic pattern, as shown in figure 1 for white males and in figure 2 for white females. The rates for each State and geographic division are given in table 1. These have been age adjusted by the direct method to the age distribution of the total population as enumerated in 1950. Also shown in table 1 are average death rates for the 3-year period 1949-51 for the age group 45-64. The geographic pattern of these rates is essentially the same as the pattern of age-adjusted rates for 1950. Deaths are those coded 420 in ac-

Mr. Enterline is chief statistician of the Heart Disease Control Program, Public Health Service, and Dr. Stewart is assistant director of the National Heart Institute, Public Health Service. This study was initiated while Dr. Stewart was chief of the Heart Disease Control Program.

Auxiliary Publication

Public Health Reports frequently receives contributions which, though worth documenting, pose technical or financial difficulties which prevent their acceptance for publication. Thanks to the American Documentation Institute, it is possible now to publish a reference and provide a central source for such material by the following process.

The author of qualified material will be asked if he wishes to have the material deposited in the ADI auxiliary publication program file at the Library of Congress, for a nominal fee (\$2 for the present). If he is willing, *Public Health Reports* will publish a note to the effect that the material, briefly de-

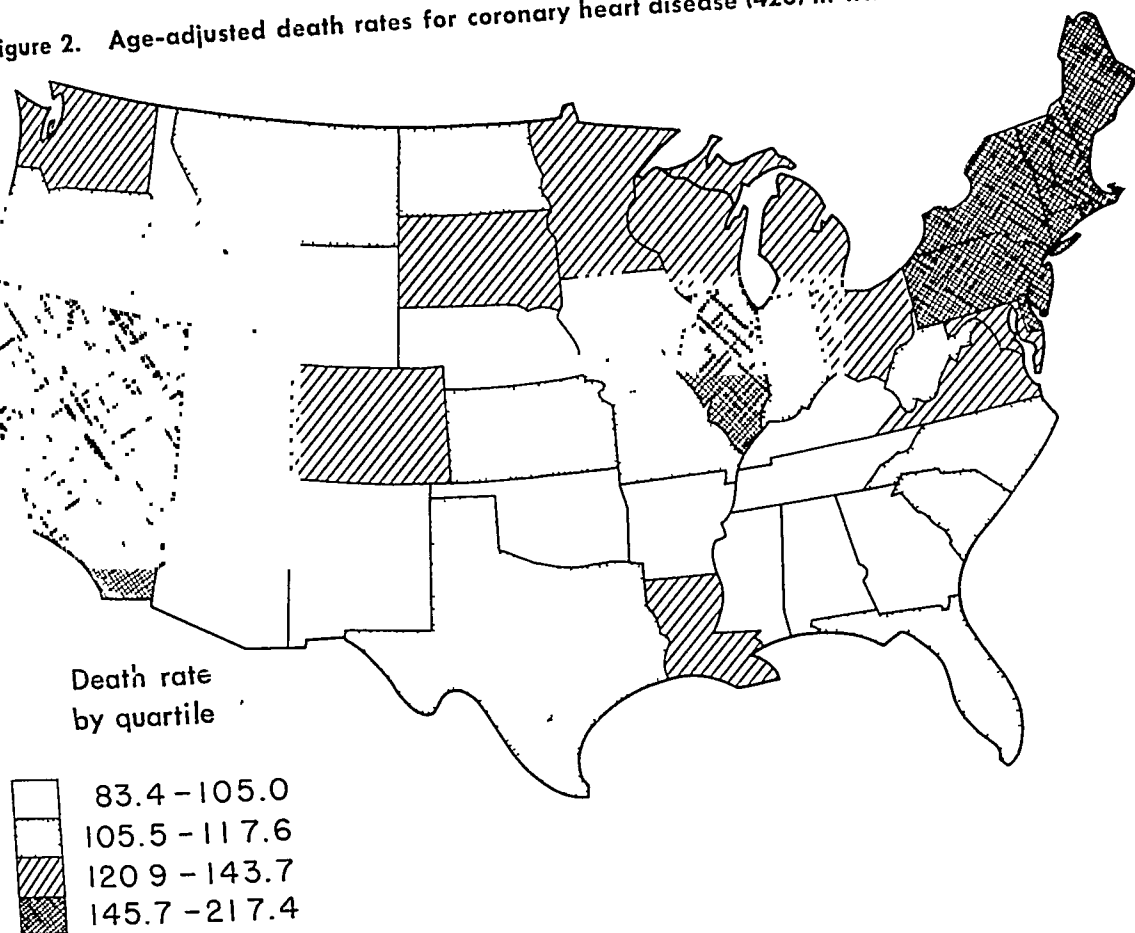

scribed, with a document number, is available from that source.

Contributions accepted by the American Documentation Institute are entered in the auxiliary publications project file and catalog, and held indefinitely, awaiting requests for copies. Copies will be furnished at the regular rates of the Library of Congress photoduplication service.

When these documents are described in *Public Health Reports* and announced to be on file, they are eligible for listing in the various medical indexes.

Such documents may consist of an entire paper or a portion of it, illustrative, supplementary, or appendical in nature.

Figure 2. Age-adjusted death rates for coronary heart disease (420) in white females, 1950.

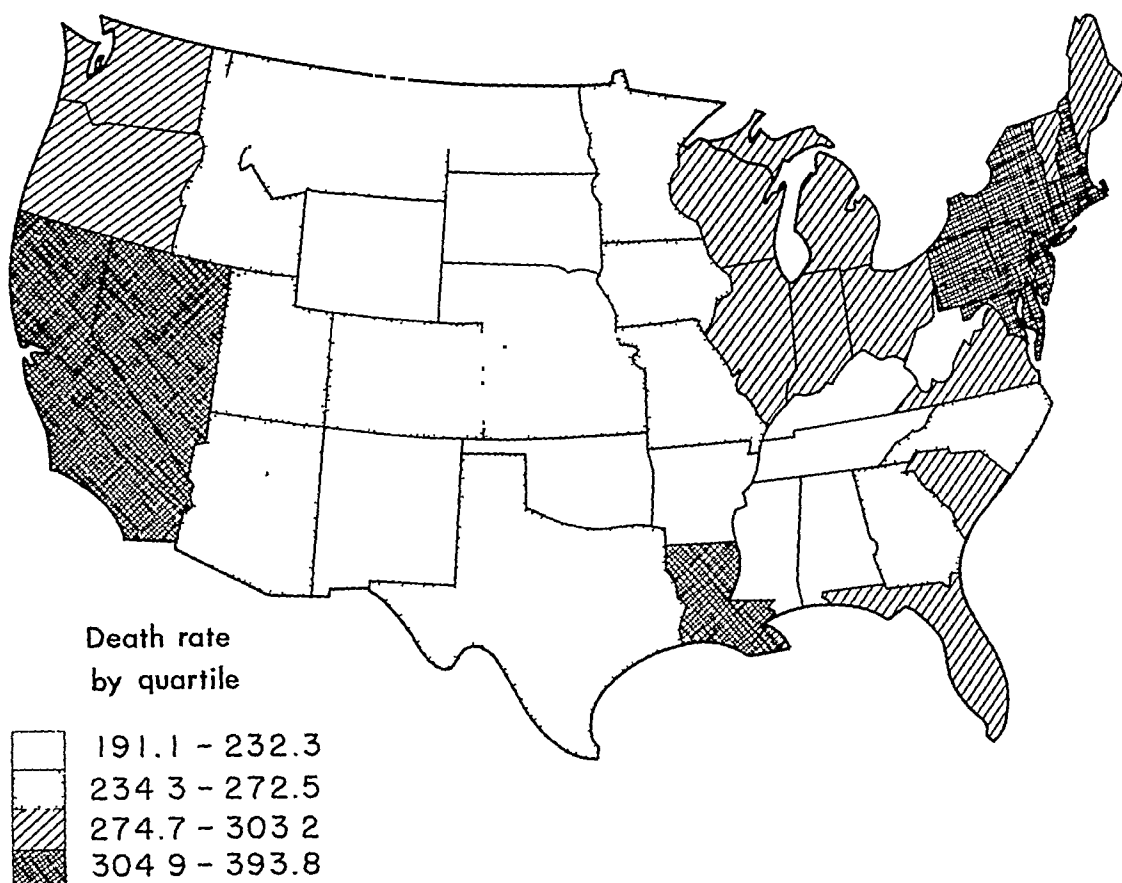

heart disease. It would be expected, therefore, that if real geographic differences in the death rates from coronary heart disease exist they would be reflected in differences in the death rates for all causes.

Data shown in table 3 for white males indicate that the coronary heart disease death rate does affect the death rate for all causes. Generally, in geographic divisions where the death rate for coronary heart disease is high, the death rate for all causes is high. This relationship is most striking in the age groups 55-64 and 65-74. In the age group 65-74 much of the variation in the death rates for all causes among geographic divisions is, in fact, eliminated when coronary heart disease deaths are excluded.

In the age group 75-84, there appear to be important differences in the diagnostic criteria used in the various geographic regions. This is suggested both by less association between the death rates for coronary heart disease and

the death rates for all causes in this age group as compared with other age groups and by a tendency for death rates for coronary heart disease to be negatively associated with death rates for all causes excluding coronary heart disease. It is probable that some deaths in the age group 75-84 called coronary heart disease in the Middle Atlantic States, for example, are called something else in the East South Central States. Diagnostic differences in the older age groups are to be expected in view of the increasing multiplicity of diseases present at time of death with increasing age, which makes identification of the underlying cause difficult. The numbers of deaths in the older age groups and the probable magnitude of the differences in diagnostic criteria are not sufficiently large, however, to account for an appreciable proportion of the geographic variation in the death rates shown in table 1.

Figure 1. Age-adjusted death rates for coronary heart disease (420) in white males, 1950.

cordance with the sixth revision of the International Lists, and they have been allocated to place of residence (1).

The death rate for coronary heart disease is roughly twice as high in some States as in others. In New Mexico, Arkansas, and Kentucky, the age-adjusted death rates among white males were 191.1, 201.2, and 211.2, respectively, as compared with death rates in New York, Rhode Island, and the District of Columbia of 393.8, 364.3, and 344.3. For white females the contrast is even greater, with death rates of 83.4, 87.8, and 89.0 in New Mexico, Arizona, and Nebraska, as compared with death rates of 217.4, 176.6, and 175.6 in New York, New Jersey, and Rhode Island. There is a definite tendency for States with similar death rates to cluster.

Because coronary heart disease has been recognized as an important clinical entity only since about 1920, it seems possible that dif-

ferences in the observed death rates among States might be due to differences in diagnostic criteria. There are, for example, differences in the amount of medical care available in various sections of the country which may in some way be associated with the likelihood of coronary disease being diagnosed at the time of death. Although the possibility that the observed differences are artificial can be tested only indirectly, the available evidence suggests that the differences in death rates in various parts of the country shown in figures 1 and 2 are real.

Effect on Deaths From All Causes

In the middle and older age groups, coronary heart disease deaths make up a large proportion of the deaths from all causes. As shown in table 2, about a third of all deaths among white males in the age group 45-74 are due to coronary

Table 2. Number of deaths from all causes and from coronary heart disease and percentage due to coronary heart disease, white males and females, by age group, 1950

Age group (years)	Deaths from all causes	Deaths from coronary heart disease	Percentage due to coronary heart disease

45-54.....	42,994	5,244	12.2
55-64.....	79,803	16,497	20.7
65-74.....	130,712	33,813	25.9
75-84.....	141,519	35,066	24.8
85 and over.....	61,785	13,448	21.8

For white females the association between death rates for coronary heart disease and death rates for all causes is similar to that for white males; that is, in geographic divisions where the death rate for coronary heart disease is high, the death rate for all causes is high.

Table 4 shows a refinement of the data in table 3 for white males in the age group 55-64. Excluding deaths due to violence from deaths for all causes does not alter the association shown in table 3. The death rates for two disease categories (list Nos. 421-422 and 330-334) that might be confused with coronary heart disease either tend to be positively associated with the death rate for coronary heart disease or show no association at all. These data strongly support those shown in table 3 in favor of real and fairly large geographic differences in the death rate for coronary heart disease. Similar data for the other age groups likewise support this conclusion. Nevertheless, it is recognized that the differences may, to some extent, be influenced by differences in diagnostic criteria.

Table 3. Death rates per 1,000 population for coronary heart disease, all causes, and all causes excluding coronary heart disease, white males in selected age groups by geographic division, 1950

sponsible for differences in mortality from coronary heart disease. These theories might be investigated very profitably by studying intensively populations in those areas of the United States experiencing high death rates from coronary heart disease and populations in those areas experiencing low death rates from coronary heart disease.

Summary

For 1950, the age-adjusted death rates for coronary heart disease for white males and white females were roughly twice as high in some States as in others.

The geographic differences are probably not due to differences in standards of diagnosis. However, studies to verify this would be desirable. In those age groups in which coronary heart disease is an important cause of death, the geographic differences in the coronary heart disease death rates are reflected in the death rates for all causes. Moreover, the death rates for two disease categories that might be used in lieu of coronary heart disease show no tendency to be negatively associated with the death rates for coronary heart disease.

The geographic differences do not seem to be due, to any large extent, to differences in urbanization in various parts of the country since they persist if rural areas are examined separately.

Whatever the factors responsible, they appear to affect males and females in about the same manner.

Some of the current theories as to the importance of various factors in the etiology of coronary heart disease might be investigated profitably by studying the populations in the areas of the United States with low and high death rates for this disease.

Possible Causes

It is productive to speculate as to possible causes for the apparently real geographic differences in mortality from coronary heart disease. One point of particular interest is the fact that whatever the causes are they appear to affect males and females in about the same manner. (There are, however, possibly meaningful differences in the ratio of white male to white female death rates; the ratio ranges from 1.8 in New York and 1.9 in New Jersey and South Dakota to 2.9 in South Carolina and Arizona.)

The most patent explanation for the geographic pattern seems to lie in an association between urbanization and mortality from coronary heart disease. It will be noted that areas of relatively high mortality in figures 1 and 2 tend to be highly urbanized. In support of this theory, Gover and Pennell reported that for 1940 the age-adjusted white death rates for diseases of the coronary arteries and of the myocardium were only about two-thirds as high in rural areas as in urban areas (3).

At this time, mortality tabulations which would permit an adjustment of the 1950 mortality rates for coronary heart disease for urbanization are not available. However, a comparison of the 1940 rates for diseases of the coro-

nary arteries and of the myocardium for urban and rural areas and for rural areas alone with the 1950 rates for coronary heart disease for each of the nine geographic divisions throws some light on the question. This comparison, shown in table 5, indicates that the same geographic pattern persists in rural areas as in the United States as a whole. (The same conclusion is reached if only diseases of the coronary arteries, list Nos. 94a and 94b, are used.) Although there were defects in the identification of coronary heart disease under the fifth revision of the International Lists, which was in effect in 1940, they probably do not invalidate the comparison. It would seem unlikely, therefore, that an adjustment of the 1950 data for urbanization would change greatly the geographic pattern shown in figures 1 and 2.

Most of the current theories which might explain geographic differences in coronary disease fall into two categories—genetic and cultural. With regard to the latter, many possibilities have been suggested, including such things as diet, exercise, and stress. All of these may play a part. There may also be hereditary factors which are manifested by differences in the physical characteristics of populations in various parts of the country (as well as in various parts of the world) and which are in some way re-

tories and rectal swabs for culture were obtained from them. Rectal swabs from the two food handlers in the school cafeteria and samples of the foods served during the preceding 2 days were also obtained for culture. The only food on the menu that could not be obtained was the potato salad served on September 21.

The parents of the school children were questioned on September 24, and data were obtained concerning the occurrence of illness, the time of onset, the clinical manifestations, and the history of foods consumed in the school cafeteria on September 21 and 22.

On September 25, *S. sonnei*, type 1, was isolated from 12 of the 18 original rectal swabs. Antibiotic sensitivity tests showed the organisms to be sensitive to aureomycin, terramycin, and chloramphenicol, but resistant to sulfadiazine and dihydrostreptomycin.

When the school reopened on September 27, all the children were questioned as to the occurrence of illness, the symptoms experienced, and the foods consumed. Rectal swabs were obtained from all the students and the staff.

Six weeks later, rectal swabs were again obtained from the students and staff, and families

were questioned concerning the occurrence of subsequent illness among other members of the household. No fecal specimens were obtained from the household contacts.

Laboratory Procedures

The fecal specimens were obtained by swabbing the walls of the anal canal with a sterile cotton swab. The soiled swab was placed in a tube containing a broth designed to act as a selective medium. Culture plates were streaked with the inoculated medium on the swab within 6 hours. The broth, which was prepared according to the formula of Hajna from the Bacto dehydrated product, is a medium in which gram-negative organisms are enriched and gram-positive organisms are inhibited (4). It has been shown by Croft and Miller to be particularly effective for the isolation of shigellae if the inoculated medium is kept no longer than 8 hours before streaking culture plates (5).

Colonies of non-lactose-fermenting bacteria from Endo and SS agar plates were transferred to triple sugar iron (TSI) agar slants. Those giving shigella reactions on TSI (alkaline slant,

Figure 1. Onset of clinical cases of gastroenteritis during the acute outbreak, September 22 through September 24, 1954.

An Outbreak of *Shigella* Gastroenteritis

By MARTIN D. KELLER, M.D., Ph.D., and MALCOLM L. ROBBINS, M.D.

IN September 1954, an explosive outbreak of gastroenteritis occurred in a rural elementary school in central Ohio. Investigation by the division of communicable diseases of the Ohio Department of Health determined that the outbreak was related to food served in the school cafeteria. The etiological agent was found to be *Shigella sonnei*, type 1.

The American literature contains few well-documented reports of foodborne shigellosis. In 1950, Feig reviewed reports of outbreaks of diarrheal disease received by the Public Health Service from 1945 through 1947 (1). During this period there were 476 outbreaks characterized bacteriologically. Of these, only 14 were associated with *Shigella* organisms (only 3 with *S. sonnei*).

In surveys of normal population groups in the late 1930's and early 1940's, Watt and Hardy found the prevalence of shigellosis by culture to be 11 percent in New Mexico, 4 percent in Puerto Rico, 3 percent in Georgia, and 0.1 percent in New York City (2). In general, the infection rate was greatest in the 1- to 9-year

age group. In a study of clinical cases of diarrheal diseases, Hardy and Watt found that *S. sonnei* accounted for 20 to 25 percent of the shigella infections in New Mexico and in Georgia and for 57 percent in New York City (3).

Investigation of the Outbreak

The first illness in the Ohio outbreak occurred at 3 a. m. on September 22, 1954, and the majority of the cases began during the afternoon and night of the same day. Through inquiry among local physicians and at nearby schools, it was determined that the illness was limited to the children and teachers of one elementary school.

The illness was characterized by fever, chills, headache, abdominal pain, nausea, vomiting, diarrhea, and prostration. In most cases, the temperature (oral) ranged from 100° to 105° F. Several cases began with convulsions. The illness usually lasted from 24 to 72 hours, and severe symptoms rarely persisted longer than 24 hours. None of the patients were hospitalized. About one-third of them were seen by physicians. The drugs most frequently used were neomycin, sulfadiazine, kapectate, and paregoric.

The school was closed before noon on September 23 because of marked absenteeism, and it remained closed until September 27. The school population consisted of 268 children and a staff of 12. On September 23, visits were made to some of the homes in the community to locate sick children. Eighteen acutely ill children were discovered in this manner, and his-

Dr. Keller and Dr. Robbins, at the time of this study, were officers of the Epidemic Intelligence Service, Communicable Disease Center, Public Health Service, on assignment to the division of communicable diseases, Ohio Department of Health. Dr. Keller is now assistant resident in medicine at the Bronx Veterans Administration Hospital, New York City, and Dr. Robbins was scheduled to become senior resident in pediatrics at the Bronx Municipal Hospital Center on July 1, 1956.

evidence of infection (clinical illness or positive culture, or both) for the same two categories. These rates offered statistically significant evidence that infection was related to consumption of the suspected meal.

Table 3 shows that for both those who ate the suspected meal and those who did not eat it the rate of clinical illness was nearly as high as the attack rate based on evidence of infection. These findings differ from the expected ratio of clinical cases to carriers.

From table 4, it can be seen that the positive culture rates were substantially lower than the infection rates. However, on the basis of one culture, the rate for those who ate the suspected meal represents a rather high percentage of isolation of *S. sonnei* from an exposed population.

Table 5. Positive culture rate related to clinical illness

Illness status	Positive culture	Negative culture	Total	Positive culture rate (percent)
Ill.....	92	59	151	61.0
Not ill.....	15	75	90	16.6
Total.....	107	134	241	44.4

Table 5 shows that positive cultures were found in 61.0 percent of the persons who were ill, but in only 16.6 percent of those who were not ill.

Table 6, which gives data for 237 of the school children, reveals that there were no statistically significant differences in infection rate for the various ages.

Detailed descriptions of symptoms were obtained for 122 of the persons who were ill. The following symptoms were reported most frequently: diarrhea, for 103 persons (84 percent); fever, for 83 (68 percent); and vomiting, for 49 (40 percent).

Information concerning the specific foods eaten for lunch on September 21 and 22 was considered to be unreliable because of the age of the patients and the general imperfections of memory. Nearly all the students ate some of all of the foods served, as is the custom in school cafeterias.

Table 6. Infection rate according to age

15.....	1	1	2	
16.....	1	0	1	

¹ Clinical illness or positive culture, or both.

Six weeks after the onset of the first illness, rectal swabs were obtained from 234 of the students and staff members of the school. Only 5 cultures positive for *S. sonnei*, type 1, were found, and of these, only 3 were for persons who 6 weeks earlier had a positive culture. For all 5, 2 consecutive negative cultures were obtained during the following 2 weeks.

Information concerning subsequent cases of gastroenteritis in household contacts was obtained from 81 families 6 weeks after the outbreak. In these families there were 109 children infected during the initial outbreak and 293 household contacts. Twenty-eight of the household contacts were infected, a secondary attack rate of 9.5 percent. The dates of onset of illness and the distribution among preschool children, school children, and adults are shown in figure 2. Illness in household members with no exposure to the source of the infection was considered a secondary infection even though it occurred on the last day of the outbreak.

Discussion

The school lunch of September 21 was considered the common, single source of infection in this outbreak of shigellosis because of its relation to the time of onset of the cases. If the lunch of September 20 were the source, the first case would have had an incubation period of 39 hours and the median of the incubation periods would have been 56 hours. The lunch of September 23 is eliminated because at least seven

acid butt, and negative H_2S) were tested with shigella group serums. After the causative organism was identified as *S. sonnei*, type 1, only the specific antiserum was used in the slide test for identifying suspected cultures.

The isolated organisms were tested for antibiotic sensitivity by the Difco disk method.

Table 1. Illness and culture data related to consumption of suspected meal

Consumption of suspected meal	Ill		Not ill		Total
	Positive culture	Negative culture	Positive culture	Negative culture	
Ate-----	92	56	13	46	207
Did not eat--	0	3	2	29	34
Total----	92	59	15	75	241

Table 2. Infection rate related to consumption of suspected meal

Consumption of suspected meal	Infected ¹	No evidence of infection	Total	Infection rate (percent)
Ate-----	161	46	207	77.8
Did not eat--	5	29	34	14.7
Total-----	166	75	241	68.9

¹ Clinical illness or positive culture, or both.

The food samples were homogenized or diluted and streaked on culture plates. Staphylococcus 110 medium was employed for the isolation of staphylococci, and Endo agar, for the isolation of salmonellae and shigellae. No pathogenic organisms were found.

Bacteriological examination of water samples taken from the school gave negative results for coliform organisms.

Results

The time of onset of illness was learned for 104 of the 151 persons who were ill. The epidemic curve is given in figure 1. After the first case, the curve showed a rapid rise, reaching a peak in approximately 12 to 13 hours. The occurrence of cases then fell off gradually, the final

case appearing 55 hours after the first. The epidemic curve indicates a single source, single exposure epidemic, and it appears that the incriminated meal was the lunch of September 21. This lunch would give an incubation period ranging from 15 to 70 hours, with a mean of 35.6 hours and a median of 32 hours. Feig reported a median of 42 hours in 6 outbreaks of shigellosis (1).

Information on the following was obtained for 241 of the 280 students and staff members: consumption of the suspected meal, occurrence of illness, and results of rectal culture. Illness was defined as the presence of two or more of the following: fever, abdominal pain, nausea, vomiting, and diarrhea.

Only the data for these 241 persons are given in tables 1 through 5. However, partial data were obtained for an additional 32 persons, 20 of whom showed evidence of infection either by illness or by positive fecal culture. No information was obtained for seven of the school population.

The number of persons ill and the number of positive fecal cultures among persons who ate the suspected meal and those who did not eat it are shown in table 1.

Table 2 compares the attack rates based on

Table 3. Clinical illness rate related to consumption of suspected meal

Consumption of suspected meal	Ill	Not ill	Total	Illness rate (percent)
Ate-----	148	59	207	71.5

Total-----	107	134	241	44.4

sided, but the duration of infection after recovery was only 32 days for *S. flexneri* and only 22 days for *S. sonnei*. These investigators felt that the chronic carrier was exceptional in bacillary dysentery and that the organism is more frequently perpetuated in the community by a constantly changing group of hosts.

Cruickshank and Swyer studied an outbreak of 32 cases of shigellosis in a residential school (8). Twenty-nine gave positive cultures initially, and the number of positive cultures decreased slowly until only one was found in the 10th week. However, 10 patients, 31.4 percent of the group, had 2 or more consecutive negative cultures followed by 1 or more positive cultures, and 5 patients had 3 or more consecutive negative specimens over a period of 3 weeks, only to yield positive cultures again. These findings indicate that the data obtained in the present study from one initial culture and one followup culture after a period of 6 weeks can give only a rough estimate of the extent of the original infection and the persistence of the infection in the group. However, the figures obtained by this method are in keeping with those found by other workers.

The Ohio outbreak appears to have been quite different from an outbreak of shigellosis in Oxford, England, reported by Davies (9). In the Oxford outbreak, the first case occurred in a school for infants, but the spread of infection seemed to be mainly in the homes. Of 74 primary cases, 47 occurred in the original school and 27 in 10 other schools. Among the 293 home contacts of these 74 cases, 234 of whom had at least one stool examination, 16.3 percent had clinical illness and 33.3 percent had positive cultures but no clinical illness. In the Ohio epidemic, the school was the immediate source of infection for 81 families. In these families, 109 children were infected during the initial outbreak, and only 28 cases of gastroenteritis were reported among their 293 household contacts. Since no fecal specimens were obtained from the household contacts, the subsequent cases can only be presumed to be related to the initial outbreak. However, it is probable that considerably more persons in these families became infected but did not have clinical illness.

The clinical manifestations observed in the

Ohio outbreak were similar to those described by Blatt and Shaw (10) and Cruickshank and Swyer (8).

Zimmerman, Cooper, and Graber studied an epidemic of shigella infection in Korea in 1952 (11). They found sulfadiazine therapy unsatisfactory. Chloramphenicol, terramycin, and aureomycin were found to be highly effective, and streptomycin was intermediate. All 13 types of shigellae that they isolated were found to be highly sensitive to chloramphenicol, terramycin, and aureomycin, but not sensitive to sulfadiazine and dihydrostreptomycin. In recent years, few sulfadiazine-sensitive shigellae have been isolated by the Ohio Department of Health laboratories.

Thus, the expense of treating shigella infections poses a special problem. In massive outbreaks in rural areas, where income may be low, it is often not possible to treat all patients with the most effective antibiotics. However, in the outbreaks described in this paper, all those who were ill recovered without apparent complications within a period of a few days, despite the fact that very few were given antibiotic therapy.

Summary

An outbreak of gastroenteritis in a rural elementary school in central Ohio in September 1954 is described. From data collected concerning occurrence of illness, time of onset, consumption of a suspected meal, and results of fecal cultures, it appeared that the outbreak followed a mass exposure to *Shigella sonnei* at a school lunch.

The first illness occurred 15 hours after the suspected meal. After this, the number of cases increased rapidly, and the peak of the outbreak occurred 27 to 28 hours after the meal. The median of the incubation periods was 32 hours, and the range was from 15 to 70 hours.

For 241 of the 280 students and staff members of the school, the following findings were obtained: Of those who ate the suspected meal, 71.5 percent became ill; of those who did not eat this meal, only 8.8 percent. From one fecal specimen taken within 8 days of the beginning of the outbreak, *S. sonnei*, type 1, was isolated

Figure 2. Occurrence of secondary cases in household contacts of persons infected during the acute outbreak.

cases had their onset before the lunch was served.

Neither of the two food handlers was ill, but both had cultures positive for *S. sonnei*, type 1. It is possible that they became infected in the same manner as did the rest of the school population. However, it is conceivable that one of them carried the organisms before the outbreak occurred and contaminated the foodstuffs served at the lunch on September 21.

The last contact the children had with one another in school during the outbreak was on the morning of September 23, approximately 46 hours after the lunch on September 21. There is a possibility that some of the late cases were secondarily infected from the early ones. However, it is reasonable to explain the epidemic curve on the basis of a single source and a single exposure.

The attack rate of 77.8 percent, based on the occurrence of illness or the finding of *S. sonnei*, type 1, or both, points to massive exposure of the population of the school. However, 39 percent of those who were ill had negative cultures, and 16.6 percent of those who had no clinical illness were shown to be asymptomatic carriers. It is reasonable to suppose that a considerable

number of asymptomatic carriers were missed since only one culture was obtained during the outbreak for each person.

Watt and Hardy found that infection without clinical disease was rare in infants, but that it progressively increased up to the age of 5 years (2). Thereafter, it occurred at a fairly uniform rate. For all age groups, the ratio of convalescent or passive carriers to each current case was 9.1. They also found that the ratios were fairly uniform for different types of shigellae. They concluded that manifest sources of infection are rare in comparison to hidden sources. In a study of shigella infection in a closed institutional population, Hardy, Shapiro, Chant, and Siegel found that the ratio of carriers to clinical cases was greater for *S. sonnei*, 24:1, than for *Shigella flexneri*, 7:1, (6).

In the present study, only 5 persons had positive cultures 6 weeks after the initial outbreak, and these became negative on at least 2 subsequent samples within the next 2 weeks. These findings are in keeping with the findings of Watt, Hardy, and DeCapito (7). Of 103 patients with proved shigellosis, 80 percent had positive cultures after the acute symptoms sub-

Survey of General Hospitals Accepting Mental Patients

By BERNARD H. KROLL, B.A., and HYMAN GOLDSTEIN, Ph.D.

DURING the period from December 1951 to May 1953, the National Institute of Mental Health of the Public Health Service conducted a survey of the general hospitals in the United States. The original purpose of the survey was to ascertain which general hospitals accepted as inpatients persons with a primary diagnosis of suspected or actual mental illness in order to bring up to date the number of general hospitals to be included in the census of mental patients. As a result of the survey, the number of hospitals included in the census of mental patients rose to 546 compared with 157 prior to the survey.

Data were also collected on type of patient accepted, hospital size, and the types of therapy available for each hospital offering therapy. It is believed that presentation of data on the types of therapy available at the time of the survey would be useful since such data would serve as a baseline for future studies of the types of therapies available in general hospitals. This is particularly so in the light of the more recent developments in drug therapy, such as the use of reserpine, chlorpromazine, and other tranquilizing drugs, the growth of

general hospital facilities for the mentally ill, and the increasing development of nonhospital treatment for the mentally ill.

Some background on the distribution in the States of the hospitals reporting and those indicating acceptance of mental patients is presented in table 1. Additional tabulations showing in greater detail the distribution of these hospitals are available (see documentation note). Of the 4,716 hospitals surveyed, 4,702, or 99.7 percent, of the hospitals queried reported. Reporting was 100 percent complete for 40 States and the District of Columbia. About 40 percent of the reporting hospitals had average daily resident populations of 50 or more. About 21 percent of the hospitals with average daily resident patient populations of 50 or more accepted mental patients as contrasted to about 6 percent of the hospitals with average daily resident patient populations under 50. It is clear that there is a significant difference in the acceptance of mental patients between hospitals with average censuses of 50 or more and those under 50.

The types of patients accepted by the 546 hospitals reporting the acceptance of mentally ill patients and the type of service offered are shown in table 2. Of these 546 general hospitals, 176, or 32.2 percent, routinely offer only diagnostic workup for patients admitted. This does not imply that occasional treatment may not be given for a selected patient, but it does mean that the hospital acts as a diagnostic and screening center, and patients who are in need

Mr. Kroll is an analytical statistician, Hospital Reports and Records Unit, and Dr. Goldstein is chief, Current Reports Section of the Biometrics Branch, National Institute of Mental Health, National Institutes of Health, Public Health Service.

from 50.7 percent of those who ate the suspected meal but from only 5.9 percent of those who did not eat it. Considering those persons who were ill or who had a positive fecal culture, the attack rate for all was 77.8 percent. Of the persons who were ill, 61 percent had positive fecal cultures; of those who were not ill, only 16.6 percent were positive.

Two food handlers gave positive fecal cultures, but they had no clinical illness. No specific food was implicated.

Six weeks after the occurrence of the first case, when 234 fecal specimens were taken, only 5 contained *S. sonnei*, type 1.

Among 293 household contacts of 109 infected children, in 81 families, only 28 (9.5 percent) became ill with gastroenteritis within 6 weeks after the outbreak. Of these, 20 were children under 15 years of age.

Other reports of shigella infection are discussed briefly and compared with the Ohio outbreak.

Traineeships for Public Health Personnel

Authorized by the Health Amendments Act of 1956 (P. L. 911), the Public Health Service has appropriated \$1 million to establish a program of traineeships for graduate or specialized public health training of professional public health personnel for the fiscal year ending June 30, 1957.

The funds will include necessary costs, such as living expenses, tuition, and travel, as determined by the Surgeon General. All professional public health personnel are eligible.

Information and application forms may be obtained from any of the regional offices of the Public Health Service, or from the Chief, Division of General Health Services, Bureau of State Services, Public Health Service, Washington 25, D. C.

Survey of General Hospitals Accepting Mental Patients

By BERNARD H. KROLL, B.A., and HYMAN GOLDSTEIN, Ph.D.

DURING the period from December 1951 to May 1953, the National Institute of Mental Health of the Public Health Service conducted a survey of the general hospitals in the United States. The original purpose of the survey was to ascertain which general hospitals accepted as inpatients persons with a primary diagnosis of suspected or actual mental illness in order to bring up to date the number of general hospitals to be included in the census of mental patients. As a result of the survey, the number of hospitals included in the census of mental patients rose to 546 compared with 157 prior to the survey.

Data were also collected on type of patient accepted, hospital size, and the types of therapy available for each hospital offering therapy. It is believed that presentation of data on the types of therapy available at the time of the survey would be useful since such data would serve as a baseline for future studies of the types of therapies available in general hospitals. This is particularly so in the light of the more recent developments in drug therapy, such as the use of reserpine, chlorpromazine, and other tranquilizing drugs, the growth of

general hospital facilities for the mentally ill, and the increasing development of nonhospital treatment for the mentally ill.

Some background on the distribution in the States of the hospitals reporting and those indicating acceptance of mental patients is presented in table 1. Additional tabulations showing in greater detail the distribution of these hospitals are available (see documentation note). Of the 4,716 hospitals surveyed, 4,702, or 99.7 percent, of the hospitals queried reported. Reporting was 100 percent complete for 40 States and the District of Columbia. About 40 percent of the reporting hospitals had average daily resident populations of 50 or more. About 21 percent of the hospitals with average daily resident patient populations of 50 or more accepted mental patients as contrasted to about 6 percent of the hospitals with average daily resident patient populations under 50. It is clear that there is a significant difference in the acceptance of mental patients between hospitals with average censuses of 50 or more and those under 50.

The types of patients accepted by the 546 hospitals reporting the acceptance of mentally ill patients and the type of service offered are shown in table 2. Of these 546 general hospitals, 176, or 32.2 percent, routinely offer only diagnostic workup for patients admitted. This does not imply that occasional treatment may not be given for a selected patient, but it does mean that the hospital acts as a diagnostic and screening center, and patients who are in need

Mr. Kroll is an analytical statistician, Hospital Reports and Records Unit, and Dr. Goldstein is chief, Current Reports Section of the Biometrics Branch, National Institute of Mental Health, National Institutes of Health, Public Health Service.

¹ Individual data will not add to the "All hospitals" totals since hospitals offer more than one type of therapy.

of treatment are usually referred to other hospitals after diagnosis. The remaining 67.8 percent of the hospitals indicate that treatment as well as diagnostic services are offered. Again this does not imply that every patient admitted would be offered treatment, but treatment would be available if it were deemed advisable. A total of 445 hospitals, or 81.5 percent of all hospitals accepting mental patients, accept psychotic patients as well as other types. Of those, 69.5 percent offer treatment and the remaining 30.6 percent offer diagnosis only. The remaining 101 hospitals do not accept psychotic patients but will accept other types; 62.4 percent of these hospitals offer treatment, and 37.6 percent do not.

However, hospitals offer varied treatment programs. Of the nine major therapy groups on which data were collected, very few hospitals offered all types. Even if all types were available, the use of these therapies would be selective and would vary depending upon the patient and the alternative therapies available.

Psychotherapy is the most widely used type of therapy (table 3); 305 or 82.0 percent of the 372 hospitals reporting treatment facilities offered psychotherapy, individual or group (57 hospitals offered group psychotherapy but 301 hospitals offered individual psychotherapy).

The next two highest groups are electrotherapy and drug therapy with 73.7 and 71.0 percent of all hospitals offering these therapies among others. The remaining therapies in decreasing order of availability percentagewise were as follows: insulin 63.7; physiotherapy 54.6; occupational therapy 38.4; fever therapy 34.9; psychosurgery 33.3; metrazol and other shock therapy 18.3; all other therapies 12.6.

Summary

A survey was made of the 4,716 general hospitals known to be in operation in the United States during the period of 1952-1953. More

than 99 percent of the hospitals queried replied. Forty percent of these hospitals had average daily resident patient populations of 50 or more. A significantly greater proportion of hospitals with average daily resident patient populations of 50 or more accept mental patients than those with populations under 50.

Of the 4,702 hospitals, 546, or 11.6 percent, accept patients with a suspected or actual primary diagnosis of mental illness. Of these hospitals, 67.8 percent offer treatment as well as diagnosis; the remaining 32.2 percent offer diagnosis only.

Psychotherapy is reported the most widely used therapy, with electrotherapy and drug therapy following closely.

DOCUMENTATION NOTE

Additional tabulations of data from this survey have been deposited as document No. 4960, American Documentation Institute, Auxiliary Publications Project, Photoduplication Service, Library of Congress, Washington 25, D. C. A photoprint copy may be obtained by remitting \$2.50; a 35 mm. microfilm copy, by remitting \$1.75. Advance payment is required. Write checks or money orders payable to Chief, Photoduplication Service, Library of Congress.

The tabulations cover the following subjects:

1. Distribution of hospitals reporting acceptance of mentally ill patients by average daily number of all patients resident in hospital during year and average daily number of mental patients in residence during the year: United States, 1952.

2. General hospitals accepting mental patients and offering diagnostic workup only by type of service and average daily resident patient population of hospital: United States and each State, 1952.

3. General hospitals accepting mental patients and offering treatment by type of service and average daily resident patient population of hospital: United States, 1952.

4. Number of hospitals offering treatment for certain detailed therapies: United States and each State, 1952.

5. Percent of hospitals offering a given therapy of all hospitals offering treatment: United States and each State, 1952.

Addressed originally to the County, City, and District Health Officers Association of New York State, this speech on performance budgeting in experimental installations merits the attention of all health administrators.

Performance Budgeting for the Health Department

By DANIEL KLEPAK, M.P.A.

THE DISTINCTION between program budgeting and performance budgeting to me is more than a question of semantics. In my opinion, program budgeting connotes the gathering of costs by program, that is, so much to inoculate children with poliomyelitis vaccine, so much for clinics, so much for nursing services. If you can separate your costs into clearly discernible programs, then you have program budgeting. Performance budgeting, however, goes further than that. Performance budgeting is the relating of program costs to workload information. If you know the total cost for inoculating children with the vaccine, you have program budgeting. If you know how much it costs to inoculate each child, then you have performance budgeting.

Performance budgeting, as a concept, is not new. For many years various governmental jurisdictions—and most large business corporations—have financed their activities in relation

to services rendered rather than according to things to be purchased. One of the earliest installations—and still highly successful—is the system used by the Tennessee Valley Authority.

Performance budgeting received the greatest impetus in government when the Hoover Commission recommended its use throughout the Federal Government. Herbert Hoover is personally credited with devising the name of a budgeting system which concentrated on ends to be achieved by government rather than on means to be employed.

To make the concept of performance budgeting a little clearer as we go along, let's look at some of the budget tables which I worked up, strictly on an experimental basis, for the Rensselaer County (N. Y.) Department of Health.

Some of these breakdowns you might consider out of keeping with the recommended organization of public health practice, but, if you have good organization in your health department, your performance budget will mirror it.

Mr. Klepak, associate budget examiner, New York State Division of the Budget, was formerly hospital consultant, New York State Commission on Fiscal Affairs of State Government, and chief of local assistance, New York State Department of Health.

The Line-Item Budget

A budget for Rensselaer County Health Department as it might look spread out in pro-

gram style is pictured in exhibit 1. The objects of expenditure on the left and the total amount in the last column on the right follow traditional budget form. The account categories are the standard categories used by counties in New York State.

The traditional budget shows what you purchase for your money, that is, the services of so many physicians, so many typists, and so many other types of personnel; so much for pencils, so much for laboratory supplies, so much for X-ray supplies, so much for fuel, and so on. It does not tell you what you do with your money. It doesn't speak in terms of services.

When an administrator plans a program, he must think about how he's going to immunize children or how he's going to run a tuberculosis hospital, not about how many typewriters, pen-

cils, and staples he will have to buy, how much X-ray film his clinics will need, how many bandages and plasters his nurses will apply, or how much fuel, light, and electricity his department will use. Unless he thinks in terms of services, his frame of reference is completely artificial and strait-jacketing.

The traditional budget gives very little indication of what a department or bureau expects to accomplish during the year. The tyranny of the line-item type of budget causes department heads to continue to think in terms of the tools they must use rather than of the programs they must plan and manage.

A Planning Cycle

Performance budgeting is nothing more than a good financial tool. It is not a panacea; it is

¹ Before distribution of laboratory costs.

not a pushbutton system. With performance budgeting, you will still need professional opinion and administrative judgment to run the department, but this approach to budgeting and to planning will help you see where to direct your energies.

In exhibit 2 we see the various cost centers, or activities or programs, of the Rensselaer County Department of Health and the work units that might be used to measure them quantitatively. In performance budgeting, we try to determine measures for what is being done in any of the health department's programs. Here we are talking about measuring services quantitatively and evaluating them quantitatively, not qualitatively.

We don't try to measure every type of work. For example, the multifarious activities of an administrator of a county health department are, in my opinion, either unmeasurable, or they would take so much effort to measure that you would get little return for your effort.

Nor do we measure social service in a county health department where it may be a very small operation. However, in a large mental hospital such as the Hudson River State Hospital at

Poughkeepsie, N. Y., where the State has been installing a performance budget system, social service is a large activity, costing approximately \$100,000. There we measure social service by a yardstick or work unit called a contact, either with a patient or his relatives or his prospective employers.

With exhibit 3 we introduce a new concept to budgeting. Here we have analyzed fixed and variable costs for the county's nursing program. If we had taken 1,000 nursing visits, let's say, and divided them into the total cost of a \$5,000 nursing program, we would have obtained a unit cost of \$5.00 for each visit. But that, we feel, is an erroneous way of thinking. Costs have different properties. Some costs are fixed. Others are variable.

In a tuberculosis hospital, for example, the cost of food increases with every additional patient fed. Food is clearly a variable cost. It increases and decreases with the number of hospital patients. But the salary of a dietitian and the salary of the head of the hospital are truly fixed or overhead costs. Since those costs remain constant regardless of the number of people cared for in a hospital, or the number of people visited in a nursing program, we discriminate, in our budgeting system, between variable and fixed costs.

If your nurses were making 10,000 visits a year, and you were to decrease the number of visits by one-half, to 5,000, you could not get along on half your prior appropriation. Only those costs which vary with workload could be decreased. Similarly, if you enlarged the scope

Exhibit 2. Cost centers and units of measurable work

Code and cost center	Work unit
01 Nursing-----	Visit.
02 Clinics-----	Clinic session.
03 Sanitation-----	{Inspection. Weighted inspection. ¹
04 Laboratory-----	{Test. Weighted specimen point. ²
05 Social service-----	None. ³
06 Maintenance-----	None. ³
07 Administration-----	None. ³

¹ All inspections classified and weighted according to personnel time spent on each type of inspection.
² New York State Association of Public Health Laboratories has recommended adoption of a uniform weighting system for all public health laboratory procedures. Because all local laboratories will probably adopt it for reporting purposes and the recommended standards are reasonably related to activities at Rensselaer County Laboratory, the system has been adopted.
³ None does not mean that no measurable units exist but rather that incurred costs are so relatively fixed that no useful planning or control purpose would be served by comparing costs with units of work done or that the identification and recording of measurable units of work would be uneconomical compared with possible benefits to be gained.

Exhibit 3. Breakdown of fixed and variable costs: nursing costs

Code and item	Variable	Fixed

300 Supplies and materials-----		
400 Other expense:		
Automobile expense-----	x	x

of your program, you would not need an increase in funds in proportion to the size of the increased workload. Your fixed costs would remain relatively constant.

Exhibits 4 and 5 show the 1955 workloads for Rensselaer County's nursing program and the clinic program as they looked in December 1954.

Exhibit 4. Nursing visits forecast for 1955

Type of visit	Number of visits in—			Forecast for 1955

Performance budgeting almost forces the program supervisor to go through a complete planning cycle. He must judge how much work he expects his program will accomplish, what kind of work it will be, and how it will be done. Without such planning, there is little basis for forecasting costs or later for comparing planned operations with actual operations.

Three exhibits—6, 7, and 8—demonstrate the standard costs of a nursing visit, clinic session, and sanitary inspection.

In exhibit 6 we have taken all the costs that

were generated by the nursing program, obtained unit costs on a visit basis for those variable costs described previously, and found that a nursing visit costs \$5.55 in Rensselaer County. In addition, there are fixed costs of \$10,788 for the year 1955.

A standard cost does not reflect what ideally a nursing visit or sanitary inspection should be in Rensselaer County. It simply reflects what is true at that time. In late 1954 it cost the county \$8.65 to make a sanitary inspection.

The fact that unit costs differ is simply an

index of a different type of operation or a more efficient operation. You cannot say that because one standard cost is less than another it is therefore better. Costs simply reflect the fact that one service is different from another. If the services are supposed to be substantially the same, then there should be administrative and professional scrutiny to determine what the difference means. It might mean better service, or it might mean inefficiency, but its meaning, whatever it is, cannot be determined from the budget. Performance budgeting

spotlights the problem. For its solution, you still need trained professional and technical personnel.

Under performance budgeting, the operating budget for a calendar year might appear as tabulated in exhibit 9. Here, instead of listing needs for fuel, pencils, and salaries, you budget as you normally plan your program. The table illustrates a budget for various programs: how much work the Rensselaer County Health Department expected to do in 1955, how much each work unit would cost, the total variable cost,

the fixed or overhead cost, and the total amount to be requested.

A performance budgeting system is coupled with a statistical and financial reporting system. No accounting or budgetary system is worth anything unless it provides useful information to management.

Values for Administration

An attempt to show the complete operations of a hospital over a year may be seen in exhibit 10. The hospital is Home Folks Tuberculosis Hospital, Oneonta, N. Y., where our division has also set up an experimental performance budget.

Actually, you can't show in one summary table, or on one piece of paper, the complete operations of a large organization and make them definitive and of great value. You would require more than that for an actual reporting system. The sample table is simply intended to illustrate the type of information you can get from performance budgeting. It will show the areas needing further scrutiny.

On the left, in column 1, we note that the outpatient department is authorized to spend \$63,431. It actually spent \$64,174. By subtracting column 2 from column 1 we see that the difference is \$743. That's as far as we go in traditional budgeting systems. But this type of summary report goes further. It shows how much work you said you were going to do.

The hospital planned 7,500 outpatient examinations, but the actual workload was almost 1,000 more. Therefore, by projecting the amount of work planned and the amount of work actually done in terms of the unit cost for a single outpatient examination, we show the planned cost in column 8 and the actual cost in column 9. Column 10 indicates that the hospital should have been able to spend \$6,211 more than budgeted for outpatient work because it performed approximately 1,000 more examinations than forecast. Therefore, column 11 shows the net result is not failure to live within the budget by \$743 but actually a net savings of \$5,468 because in fact the outpatient department did \$6,211 worth of additional work for only \$743.

Standard unit cost (variable)		Workload expressed in terms of cost (workload \times unit cost)		Savings or overspending caused by changes in workload (col. 9 - col. 8)	Savings or overspending beyond workload requirements (col. 3 + col. 10)	Cost center or department of the hospital
Original work units	Expressed in patient-days	Planned (col. 4 \times col. 6)	Actual (col. 5 \times col. 6)			
(6)	(7)	(8)	(9)	(10)	(11)

Administrators of health programs undoubtedly are interested in the direct uses of the performance budget. Here, we simply itemize some of them.

For Expenditure Control

Continuous cost consciousness is developed at all levels. Variances from budget show up currently.

"Responsibility accounting" concept places responsibility for cost as well as program control on operating supervisors.

Fixed-variable concept points up how costs should relate to workload.

Use of standard costs encourages the setting of staff performance standards.

Planned and actual workload and costs are compared and analyzed currently.

High-cost operations are spotlighted for study on an administrative management basis.

For Budgeting

Data are available for policy decisions; for example, evaluation of boarding care as compared with institutional care.

Costs may be compared among units or institutions and private agencies, for example, private laundry service as compared with institution laundry service, or production of vaccines in commercial laboratory as compared with public laboratory.

Costs are related to accomplishments and objectives so that evaluation of use of funds is facilitated.

Standards, once they are developed, can be examined throughout the year. Once accepted, the budget process becomes one of making decisions as to extent of the program, for example, the number of patients to be hospitalized or the miles of road to be constructed. In this way, it is possible to even the budget examination process so as to reduce or eliminate the peak rush of budget making.

For Presentation

You can tell at a glance the cost of a program or activity and, in many cases, the cost of each unit.

The budget becomes more informative and understandable.

Insecticide Resistance Of *A. quadrimaculatus* In Bolivar County, Miss.

By WILLIS MATHIS, B.S., H. F. SCHOOF, Ph.D.,
KENNETH D. QUARTERMAN, B.S., M.P.H., and
RICHARD W. FAY, Ph.D

The data represent the first detection of resistance in Anopheles quadrimaculatus to chlorinated hydrocarbon insecticides and initial establishment of anopheline resistance to dieldrin.

• • •

DESPITE the widespread use of DDT residual applications for the eradication of malaria in the southeastern United States during the period 1946 to 1950, there has been no indication that *Anopheles quadrimaculatus* (Say) has developed resistance to this compound. Kruse and associates (1) reported that *A. quadrimaculatus* became less susceptible to larvicidal treatments of DDT in the Tennessee Valley Authority malaria control program, but later studies (2) indicated that factors other than resistance were responsible for the apparent lack of effectiveness of the control operations.

However, field studies in Bolivar County, Miss., now demonstrate that, while *A. quadrimaculatus* in that area is still susceptible to DDT, it is highly resistant to dieldrin, BHC, and chlordane.

The authors are all with the Communicable Disease Center of the Public Health Service. They are stationed in Savannah, Ga., with the Technical Development Laboratories where Mr. Quartermann is chief. Mr. Mathis and Dr. Fay are entomologists, and Dr. Schoof is chief of the Biology Section.

The first indication of resistance in this species was noted in field tests, employing the method of Fay and associates (3). In these tests an average 24-hour mortality of 15 percent was obtained when 62 adult mosquitoes (3 replicate tests) were exposed to paper treated by immersion in a 0.25 percent dieldrin-xylene solution.

To substantiate this apparent loss of susceptibility to dieldrin, further tests were conducted with paper treated by immersion in 0.25 percent and in 1.0 percent dieldrin solutions. DDT-treated surfaces also were assayed. The female mosquitoes used were collected from natural resting places at five widely separated locations in Bolivar County during June and July 1955 and held overnight with food and water before their exposure to chemical residues. The results of these tests clearly indicated that *A. quadrimaculatus* was highly resistant to dieldrin residues although quite susceptible to deposits of DDT (table 1).

Since the dosage of the toxicants per square foot was unknown in the foregoing tests, additional tests were run using the technique of Fay and associates (4) in which plywood panels were treated with known dosages of the toxicant. Four chemicals were evaluated: DDT at 200 mg./sq. ft., dieldrin at 25, 50, 100, and 200 mg./sq. ft., BHC at 50 mg./sq. ft., and chlordane at 100 mg./sq. ft. The exposure period was 30 minutes, except for the DDT tests in which 30-, 60-, and 120-minute periods were employed.

To compare the susceptibility of the Bolivar County *A. quadrimaculatus* with that of non-resistant *A. quadrimaculatus*, parallel tests were conducted at the Public Health Service Technical Development Laboratories, Savannah, Ga., with a laboratory-reared strain (TDL). The adult mosquitoes of the TDL strain were processed in the same manner as the Bolivar County adults. The plywood panels used in the tests were sprayed in quadruplicate sets at Savannah. After the treatment, two sets of panels of each dosage were tested at Savannah against the laboratory strain. Two sets of panels (one

Table 1. Percentage mortality in 24 hours of female *Anopheles quadrimaculatus* exposed for 45 minutes to dieldrin and DDT residues

Check.....	15	341	3

¹ Based on Abbotts formula.

tested, one untested) were then forwarded to Mississippi. A similar pair of panels was retained at Savannah.

From the results of the panel tests with residues aged 1 to 13 days, it is readily apparent that the Bolivar County strain is highly resistant to dieldrin (table 2). Deposits of 100 and 200 milligrams per square foot produced average mortalities of 5 percent or less for this strain, compared with the 98 percent mortality achieved for the TDL strain with 25 milligrams of dieldrin per square foot. The data likewise show that the Bolivar County strain has little susceptibility to BHC and chlordane at the dosages normally used for residual applications.

Although the 30-minute exposure to DDT resulted in low mortalities for both strains, these low rates are considered to reflect the length of the exposure period rather than resistance to the pesticide. In 1948, tests with the TDL strain at 30-minute exposures to 200 milligrams of DDT per square foot produced average mortalities of 44 percent (4). In the present tests with the Bolivar County strain, the mortality rates were 51 and 85 percent, respectively, following 60-minute and 120-minute exposures to replicate panels, each sprayed with 200 milligrams of DDT per square foot. Moreover, exposure to paper treated with 1-percent DDT produced an average mortality of 96 percent for the Bolivar County strain (table 1).

The development of resistance in this species to dieldrin, chlordane, and BHC apparently is due to the extensive use of these pesticides in agriculture and for the control of malaria mosquitoes. Bolivar County is largely agricultural with cotton the chief crop. Insect control on cotton requires repeated insecticidal applications, many of which are made by airplane dusting. According to the Bolivar County agricultural agent and the local pesticide companies, the insecticides used in 1955 in the order of the quantities dispersed were dieldrin, toxaphene,

¹ In one test the mortality was only 13 percent; in the remaining three it was 94, 100, 100.

² 1-day-old residues (2 replicates) gave 87 percent mortality.

³ Mortality for individual tests ranged from 13 to 95 percent.

⁴ 1-day-old residues gave a mortality of 25 percent; 13-day-old residues, a mortality of 83 percent.

endrin, DDT plus BHC, DDT, and aldrin. DDT generally is not used until August, whereas the other pesticides are employed as early as June. Presumably, the airplane and ground dusting techniques employed provide ample opportunity for treating both the larval and adult stages of the mosquito. In addition, Bolivar County has conducted a residual spray program for malaria control in rural areas since 1944. DDT and DDT-chlordane formulations have been used in this program, the latter since 1950.

The level of susceptibility to dieldrin was suggested in 1953, in Mississippi, when heavy dosage of this chemical (0.5 to 1 lb./acre) failed to provide control of anopheline larvae in rice fields (5) even though similar applications in landlocked ponds near Savannah, Ga., had been satisfactory (6). In the Savannah tests, however, the general mosquito population was only slightly affected by the test applications, whereas in Mississippi the dust treatment of cotton exposed both the adult and larval stages of the mosquitoes to the insecticides over considerable areas.

An attempt is now in progress to colonize the

Bolivar County strain so that it will be available for bioassay purposes.

Army Posts Fluoridate Water Supplies

There are 21 Army posts in the United States, Alaska, Hawaii, and Puerto Rico which now fluoridate their water supplies, according to recent information made available by the Army Surgeon General.

Requests for fluoridation are submitted to the Surgeon General and are accompanied by a report on the natural fluoride content of the water on the post and a statement of the number of persons to benefit from the procedure.

The age of the population at an installation is one of the criteria for determining the priority for setting up the fluoridation process. A census must be taken of the number of persons under 12 years of age, the number between 12 and 16, and those between 16 and 20 years living on the installation and reported with the application for fluoridation.

The Committee on Dentistry of the National Research Council has supported fluoridation of water supply for use on military posts whenever feasible and especially where there is a child population in residence. The Army Medical Service approved the fluoridation of drinking water at Army installations in July 1954.

The Queens Rehabilitation Program is designed to provide total rehabilitation for children handicapped with orthopedic, neuromuscular, or cardiac disabilities through enlisting the cooperation, and coordinating the activities, of professional groups, interested agencies, organizations, and individuals in the community.

Queens Rehabilitation Program for Handicapped Children

By LEONARD W. MAYO, S.Sc.D., and ROBERT M. WEBB, M.S.

NO MATTER what the size of a community, its future rests on the well-being of each of its members. Among the members of every community are those who are economically deprived, emotionally or mentally ill, or physically handicapped. These impairments are often such that they interfere, to a greater or lesser degree, with adequate functioning on the part of the individual in the community's

enterprises, whether these enterprises are learning, making profitable use of leisure time, or earning a living.

In order to sharpen the focus from a broad and hazy look at the variety of differences in communities and in individuals, let us adjust our lens to pick out one physically handicapped child in a large metropolitan area and try to discover what may be done to help him through a more effective organization of the community.

Seen by a casual observer, Harry appears to be a pretty normal boy. His eyes are alert and clear, and he looks intelligent; his shoulders are broad and sturdy; and his appearance is neat, at least not any dirtier than the usual accumulation which 12-year-olds can assemble without obvious effort. But if you watched him walk, you would not notice the upper portion of his body because his right leg has been amputated at the knee, and he uses crutches.

Understanding for Harry

People who see Harry on the street for the first time usually react with pity. Sometimes they offer to help him across the street or give him a seat on a crowded bus. Some turn their eyes away so as not to embarrass him. Sometimes his contemporaries show a different reac-

Mr. Mayo is director of the Association for the Aid of Crippled Children, New York City, an agency devoted to the interests of handicapped children and youth. He has had long experience with child welfare programs. At one time a high school teacher, a director of athletics, and the chief parole officer of a training school, he is, in addition to numerous civic and national posts, the honorary president of the International Union for Child Welfare and on the board of the Child Welfare League of America.

Mr. Webb has been director of the Queens Rehabilitation Program, Jamaica, N. Y., since its inception in 1954. His earlier career included posts with the Department of Welfare and the Domestic Relations Court, New York City, the Queensboro Council for Social Welfare, Jamaica, and the Stamford (Conn.) Community Council.

tion: "Hello, Crip. Bet you can't do this." Whatever their reaction, it is frequently not one of acceptance, understanding, or a desire to help. As a matter of fact, most people, adults as well as children, do not know how to help. They may remember Harry when they are asked for money for Easter Seals or the March of Dimes as a kind of payment to the gods for their own healthy bodies, but they are not very likely to get Harry into their clubs at church, their activities at school, or their outings at the beach unless they do so in a way that makes him feel "special" and "different."

What is Harry really like? How does his family feel about him? How does he feel about himself? What does he need to help make him whole? Can he find this help in his community? Taking everything into account, what can his neighbors and the community do in a practical and constructive way to help him make the grade and, at the same time, add to his own self-respect?

In Harry's community, the Borough of Queens in New York City, there is a demonstration program set up to help answer these questions. Sponsored and financed initially by the Association for the Aid of Crippled Children, it is called the Queens Rehabilitation Program. Part of the program is a diagnostic and evaluation center, called a division, in one of the public hospitals in the borough. Harry's physician learned of this, and sent him there to be thoroughly studied so that recommendations could be made for his rehabilitation—emotional, mental, and spiritual, as well as physical.

Harry and his mother came to the diagnostic and evaluation division of the Queens Rehabilitation Program where an appointment had been made. Harry did not have to wait in a cheerless room for a long time. He waited a while because it is a busy place, but the room is attractive, and there are magazines and books to look at. The physician saw Harry and his mother in a private examination room. When Harry had been given a thorough medical examination, a social worker talked to the mother and learned about the home, the other children in the family, and their relations with each other, the father and his job and earning capacity; the mother's feeling about Harry ("Harry's

a good boy, but he broods an awful lot") and her attitude toward his disability ("Of course, I love him, but, well, it's hard to know how to treat him like the others. His crutches and all make him different").

That same day, if there was time and Harry was not too tired, or maybe another day by appointment, Harry saw a physical therapist who made an evaluation of his muscular development, his ability to walk, to climb stairs, to handle his crutches, and the strengths and weaknesses of his limbs. An occupational therapist saw him, too, and tested his coordination, his ability to dress and undress, and his capacity for the many activities of daily living. A speech therapist tested his facility with words, and a psychologist gave Harry a battery of tests which showed his intellectual capacity, his learning ability, and his deeper attitudes and feelings about himself and his relation to other people. A medical specialist in orthopedics took a careful look at his leg to determine whether it was possible or advisable to use some appliance other than crutches to help him walk.

Finally, after all these specialists had an opportunity to become acquainted with Harry and his family, and after they had made a thorough evaluation of him and his needs from their own points of view and consulted with each other to check their findings; after all available information from his school, his church, his family, and other agencies which have had to do with him in the past was correlated—the team got together and put all the pieces into one comprehensive and total evaluation of Harry as a whole person. What did they find?

Harry's is a relatively simple story. He set off one Sunday, ostensibly for church, with some change in his pocket for the collection but landed instead in a movie theater. Timing himself so that he would get home when he was expected, he left the theater to cross the street to a bus stop. As he ran from behind a parked car, he stepped into the path of an automobile, leaving no time for the driver to stop. Amputation saved Harry's life but cost him his leg.

Before the accident Harry had not been happy at school. He attended sporadically, using any available excuse to stay away, truanting with increasing frequency despite punish-

ment. Examinations showed that his hearing was defective, but this was not known until after the accident. His brothers and sisters, although not as well endowed intellectually, did better at school and were favored by their parents for this reason. Harry's father resorted to severe physical punishment to deal with him, and this, combined with the obvious preference shown by his mother for the other children, made the boy feel rejected and bitter. He was ready to use his disability as a means of getting even with his parents and as a means of avoiding school legitimately. Yet, at the same time he thought of his amputation as a punishment for his truancy and particularly for his deceit in not going to church the day he was injured.

The Rehabilitation Program

What to do for Harry? A useful and simple solution would be to fit him with a prosthetic appliance so that he could walk without crutches and look very much like other boys.

Simple? Yes, except for the painstaking patience Harry would need to learn to walk again, to go through with the fittings and adjustments, and to get accustomed to the artificial leg. Above all, Harry had to want to walk and be willing to give up the newly found means of getting attention and favored treatment his crutches had given him.

Another easy matter would be to supply him with a hearing aid so that he could follow the teacher's instructions and understand the work in class and thus be able to put his intelligence to use. Easy? Yes, except for the adjustment to the hearing device and the reshaping of a boy's whole lifetime of feelings about school and other people.

And what about Harry—not merely his physical problems, as important as they were—but Harry as a person? A pattern of truancy is not easy to change. A fear of physical punishment for any infraction of rules is not readily overcome. The deep guilt which Harry felt because "God punished him" by destroying his

leg is difficult to clear up. If it takes time to learn to use an artificial leg and a hearing aid, how much more time and skill are needed to set straight the deep emotional disabilities that had ridden him even longer, and that his poor hearing and his traumatic experience served to aggravate?

The diagnostic and evaluation division of the Queens Rehabilitation Program sent its recommendations to Harry's physician, who arranged to get the prosthetic appliance and the hearing aid. At the physician's request, the physical therapist at the division helped to train Harry in the use of his new leg, and the speech therapist taught him to use his new "ears." Their work was carefully checked as they went along by competent medical men—Harry's own physician and specialists. But Harry's physician was at a loss to know where to get the help that the recommendations made it obvious Harry needed. He fully accepted the recommendation for guidance for Harry and his parents, but where could he turn to get the expert advice?

The physician understood that the Queens Rehabilitation Program included services other than those of the diagnostic and evaluation division, for a friend of his was serving on a committee of the program which concerned itself with the development of such services as Harry and many other handicapped children need.

It is the aim of the program to locate the children who need service, to acquaint the agencies, hospitals, and other facilities with their needs, and to stimulate such organizations to provide the care which the children require. Harry's physician is one of hundreds of Queens citizens who take an active part in this endeavor, and he knows that Harry's case is not unique. Although it was an accident that caused the boy to lose his leg, there are children suffering from poliomyelitis, cerebral palsy, muscular dystrophy, and cardiac conditions, and children who are congenitally malformed or who have suffered a birth injury. Many need help, and it is for all, rather than for any one group exclusively, that the Queens Rehabilitation Program exists. The program is planned to demonstrate that, through community organization methods, it is possible to help the handicapped children of a community with the services that exist or can be developed, and

that it is not always necessary or desirable to construct a building in which to house a rehabilitation center.

How is this being accomplished? What are the methods and tools of community organization, and how can Harry and others be better served because of them? As those experienced in the process will know, community organization is neither coercion nor manipulation, nor does it consist of imposing a pattern upon a community according to a preconceived plan, whether or not the community wants it. Community organization provides for bringing the principal elements of a community together under skillful leadership to face the most important things that need to be done in any field, deciding how they can be accomplished, and then carrying out a plan of action. In the Queens Rehabilitation Program, these things were done in the following way.

Basics of Community Organization

First there was an idea. In this instance, the idea was that a better job could be done in finding and treating the handicapped children and youth of the Borough of Queens. The idea had to be tested against the experience of responsible persons. It was discussed with public officials, department heads, hospital administrators, and experts in rehabilitation. When it seemed to be correct, according to the advice received from these persons, the next step was to get together a representative group of Queens residents and lay the idea before them for their reactions and their suggestions. They were the people who knew their community and might be expected to be able to give a correct evaluation of their community's willingness and readiness to accept a demonstration such as the one proposed, to work with it, and to cooperate in its aims.

Here was the place where a fundamental concept of community organization was used, namely, that no program may be expected to succeed unless the responsible leadership of the community is behind it. The group called together was representative in the statistical rather than the sociopolitical sense, as Alexander and McCann (1) make the distinction. That is to say, there were people from educa-

tion, government, medicine, social work, and civic and fraternal work—not elected by the organizations to which they belonged, and not officially speaking for those organizations. For example, the president of the medical society expressed the general views of organized medicine, but he was not delegated by the society for the purpose of expressing its majority opinion on a specific issue.

The group, designated later as a planning and coordinating committee, discussed the plans and proposals which had been submitted to it by the Association for the Aid of Crippled Children and suggested some amendments.

After several meetings, there was agreement that a demonstration program should be undertaken in Queens, and that it should have five main areas of concern: case finding, care and treatment, recruitment and training of professional personnel, public education, and research. In order to work out the details of methodology, separate subcommittees were set up. Again, careful selection was made to assure the participation of as representative a group of people

as possible in order to secure the advice and guidance of the people most closely concerned with the work with handicapped children and to make sure that these people took an active partnership role in the development of the program. It was considered important that its growth should be along lines which they chose as important, and that, as it progressed, it should be their program and not one imposed on them or which they were "talked into" supporting. It is a simple but important principle of community organization that sound progress is achieved only when the community itself understands, supports, and is a part of that progress. It is frequently easier and faster to raise funds for the construction of a building than to work out other and perhaps better ways of serving people, but accomplishments are more likely to be permanent when they are planned and carried out jointly even though it may take three or four times as long to achieve results.

As an example: it is very important to ascertain certain facts about a community before try-

ing to help solve a problem. One way to obtain facts is to have a survey made by experts from outside the community. These experts, having in mind an ideal, can quite quickly examine the community to see how closely it approaches perfection; then, they can, again with a considerable amount of speed and with great accuracy, record the comparison between present fact and ideal goal, and, finally, they can draw conclusions and make recommendations based upon their expert knowledge. In certain circumstances, and to meet the needs of certain communities, this kind of survey is useful and valuable. But sometimes the experts leave the community nothing more than a list of improvements which it should make to bring itself closer to the ideal. What happens then? The reaction, more often thought than stated, is very likely to be: "So these experts have examined us under their microscope and have found out that we ought to do thus and so. Why should they tell us how to run our town? They simply do not understand our situation. If they think such and such should be done, let them do it. We like our town as it is, and no imported expert can tell us otherwise."

But there is another way to conduct a survey, or in any event there are certain things a community can and should do before the experts come in. It takes longer and is more work for all concerned, but it is also more likely to produce lasting results; that is, the community can set up committees of its own citizens. They need not be experts, but they must be interested and intelligent individuals with a broad outlook. They should examine their community and find out the important facts about it. Having found them, they should study and decide whether or not the facts indicate correction. They should spend a lot of time at this job, and they may make some false starts. They should have professional assistance; this need not be an expert in the usual sense but a community organization worker who can provide the technical knowledge and act as the spark plug and generator for their machine. When their survey is complete, these citizens can make their recommendations to their fellow townsmen, and then the reaction of the community may well be: "We have looked at our town, and we find

that we need thus and so. We know that we need it, and we want to do something about it. We intend to see that something is done, and we do not intend to relax until it is done."

In Queens many people have been involved in planning ways to provide better service for the handicapped children in the community. Committees in which physicians, ministers, nurses, social workers, businessmen, housewives, and health educators worked and talked together have met over a period of years. Some of them were set up for specific purposes of relatively short term—for example, to plan the establishment of the diagnostic and evaluation division: Where should it be? What kind of a staff should it have? What should be the job of the various members of its staff? What children should it serve? How should they be served? Others were formed along more general lines—for instance, to work for the integration of service to handicapped children within the framework of existing casework and group work agencies: What services existed in Queens? How far were they serving handicapped children? Were they prepared to go further? What major gaps in service existed? How much understanding was there on the part of the staffs and lay leadership of those agencies as to what is meant by total rehabilitation? What was the best way to get more understanding?

As in the example given above of two ways to conduct a factfinding survey, there was a conscious choice made in Queens between two ways of serving handicapped children. It would have been possible to conduct a fund-raising campaign for a building to house treatment facilities, to employ expert campaigners, and to gather the necessary money. A new service, admittedly needed, would then have been superimposed on the existing community resources, without relation to any of them or coordination with their purposes. Instead of taking that more usual direction, those who planned the Queens Rehabilitation Program decided to spend time, effort, and money in pulling together the common interests of many people and organizations. By developing a general concern, providing a means for getting real understanding, and offering a channel for cooperative

effort, it was believed that the results would be more permanent and more securely based.

What has all this done for Harry? His physician knows that the boy needed the services of a skilled caseworker and that his physical adjustment would not progress very far until he and his parents were on better terms. The service which Harry needs is now available to him through a family casework agency, and he and his parents are consulting regularly with a staff member there. It was harder to get Harry's mother to accept the need for that than it was to make her understand the need for an artificial limb, but progress is being made. Similarly, it is harder to work with a group of agencies to the end that they develop services for themselves than it would have been to say, "You need a rehabilitation center. We will build it for you."

Working together for an aim which the community wants and knows it wants and needs, mobilizing all available resources of mind and heart and strength for a mutually understood goal—these are community organization methods. They are applicable, with suitable adjustments, anywhere, for any community, under public as well as private auspices.

Have the results justified this approach?

Tangible and Intangible Results

Thus far the results have been of two kinds. One is tangible and concrete: A casework agency has inaugurated a special program for handicapped children integrated with its regular service to families and children.

A group-work agency has developed an experimental project to work with handicapped girls as a part of its general program. A special course for teachers who have handicapped children in their regular classes has been set up. School guidance counselors have been made acquainted with careers in health work and the variety of skills and interests which their pupils may develop in order to prepare for such careers. Two hundred children have been evaluated at the diagnostic and evaluation division in the Queens Hospital Center; many of them have been given muscle reeducation, have had appliances fitted, have been guided in the activities of daily living, or have had counseling service. Two other hospitals have also set up the beginnings of a treatment service.

The other kind of result is intangible and not capable of scientific measurement. For example, many people are more aware of the fact that handicapped children are children—that youngsters like Harry are not pathetic labora-

tory specimens of deformity but are children with feelings, reactions, emotions, and sensitivity. By the simple process of working together in committees on common problems, physicians, social workers, and other specialists have come to a greater acceptance of each other's skills; representatives of various groups have come to see that they have mutual concerns; people in different walks of life have arrived at an understanding of what each has to contribute to the

other and of what all have to give to the total community. The accomplishments of the program are their accomplishments, not the achievements of outsiders.

Surgeon General Burney

Dr. Leroy E. Burney, a career officer in the Public Health Service, became the eighth Surgeon General of the Public Health Service on August 8, 1956. He succeeds Dr. Leonard A. Scheele, who resigned to become president of the Warner-Chilcott Laboratories.

Preceding his appointment, which is subject to United States Senate confirmation, Dr. Burney was State health commissioner of Indiana and secretary of the Indiana State Board of Health, on detail from the Public Health Service from July 1, 1945, to August 1954. For the next 2 years he was Assistant Surgeon General and deputy chief of the Bureau of State Services of the Public Health Service. He had been assistant chief of the Division of State Relations in 1943 and 1944.

Dr. Burney established the first mobile venereal disease clinic service in Brunswick, Ga., in the late thirties. In 1945, on detail to the Navy for 5 months, he was sent overseas by the War Shipping Administration to devise effective control measures for communicable diseases, especially the venereal diseases, in various Mediterranean ports. On returning to the United States, he became director of the former Public Health Service District 4 (now a part of Region 7) at New Orleans.

Dr. Burney joined the Regular Corps of the Public Health Service in 1932 after completing his internship at the United States Marine Hospital in Chicago in 1931 and subsequently receiving an M. S. degree in public health at the Johns Hopkins University School of Public Health, which he attended on a Rockefeller fellowship in 1931 and 1932. He received his doctorate in medicine from Butler University and the bachelor of science degree from Indiana University.

Dr. Burney is a past president of the Association of State and Territorial Health Officers and has been an active member and officer of various State and national medical and public health associations. He was born at Burney, Ind., on December 31, 1906.

tuberculosis:

hospital or home care

Papers selected from the joint annual meetings
of the National Tuberculosis Association, American
Trudeau Society, and National Conference of
Tuberculosis Workers, New York City, May 20-25, 1956

THE IMPORTANT POTENTIAL source of new tuberculosis infection is the person with tuberculosis who is outside the control of a tuberculosis service. Even though progress in saving lives has overshadowed the tragedy of tuberculosis, progress in preventing the disease has been relatively slow: While mortality has declined, it appears that the decline in morbidity has not kept pace.

It seems that the heralded drugs—isoniazid, streptomycin, and para-aminosalicylic acid—may not kill all the tubercle bacilli in patients, even though these drugs effectively inhibit multiplication of the micro-organisms.

With the new drugs, and with infectiousness capable of being brought under control in a relatively short time, the stay in the hospital is shortened for many a patient. But even then, he must continue treatment at home. Without

utmost caution and continued drug treatment for a year or more, the disease may flare up, the patient becomes infectious again, and the circle of infection is set in motion once more.

Of major concern in tuberculosis control programs, the nonhospitalized patient is the subject of the Public Health Service survey reported by Dr. Robert J. Anderson at a special session of the National Tuberculosis Association annual conference, New York City, May 20-25, 1956. Dr. Anderson's report is reproduced on the following pages along with other selections from the conference: a paper on the social significance of chronic illness with a case history of home care for a tuberculosis patient by Lucille Smith, abridgments of papers by Ruth B. Taylor and Dr. Sabine M. Holin and associates, and abstracts of 10 papers selected for their interest to health department workers.

The Nonhospitalized Tuberculosis Patient

—Program Implications—

By ROBERT J. ANDERSON, M.D., HERBERT I. SAUER, VERNA SMITH,
and DORIS E. ROBERTS, B.S., R.N.

DESPITE the continuing decline in the mortality and new case rates from tuberculosis, a considerable problem still remains in the detection, treatment, and rehabilitation of the tuberculosis patient. The resistant nature of the problem is made manifest by the relatively slow decline in the morbidity rate. Consequently, the problem of treating and following active cases in the population is a stubborn challenge to all public health workers.

With the advent of the new antituberculosis drugs, the need for prolonged stay in hospitals has been diminished, and care of tuberculosis patients at home has become increasingly accepted. In the last few years there has been great concern about these patients. Several reasons underlie this concern: Many areas now have vacant tuberculosis beds which could be

used effectively for the treatment of tuberculosis; drugs are now available which may be given effectively to patients at home; and the need for intensive supervision of cases is more fully recognized.

Finding cases and supervising them once they are found are the two main activities in tuberculosis control. Finding cases is achieved by searching for the unknown cases not yet discovered by X-ray surveys or other means, for the unreported cases which have been diagnosed but are not as yet reported to the health department, and for the known cases which have become lost or are not followed because of lack of staff or other reasons.

Even today, when we are concentrating our attention upon known cases, we must recognize the importance of those which are unknown and unreported.

Provisional reports for 1955 show a total of approximately 100,000 newly reported cases for the continental United States alone, of which more than 75,000 were active or probably active, a rate of 46 cases per 100,000 population (fig. 1). The slow decline in newly reported cases of about 4 percent a year thus continues. Moreover, tuberculosis deaths show the smallest percentage decline since the introduction of chemotherapy almost a decade ago.

While the concern of this presentation is with known cases outside hospitals, we remain aware that constantly a large number of new cases is being added to the total load.

Past observations and empirical judgments form the basis for much of our present tuberculosis control programs. New facts and meas-

Dr. Anderson, assistant chief for operational research, Division of Special Health Services, Public Health Service, delivered this paper at the annual National Tuberculosis Association meeting, May 24, 1956. The other authors are all with the Tuberculosis Program, Division of Special Health Services, Public Health Service. Mr. Sauer is a statistician, Mrs. Smith, a health program adviser, and Miss Roberts is chief nursing consultant.

Important contributions to the study were made by Dr. Paul A. Pamplona, Genevieve S. Jones, Gladys M. Ray, Zella Bryant, Ruth B. Taylor, Dorothy E. Rogers, Sara B. Pearson, and Jewel G. Wyman, all with the Tuberculosis Program at the time.

Figure 1. Newly reported tuberculosis cases and tuberculosis deaths, United States, 1930-55.

urable characteristics of tuberculosis patients give us the foundation for realistic programs for the future in supervising cases after they are found. The Tuberculosis Program of the Public Health Service has been active in the past 2 years in a study of nonhospitalized tuberculosis cases known to health departments in 37 areas, representing the Nation, with a total population of almost 7 million. The latest information on these cases was obtained from physicians, clinics, hospitals, social workers, and public health nurses. Some of the information derived from this study supports our beliefs, and some of it demands a change in our concepts and approaches. A paper describing some of the general findings and the methodology of the study was published in February 1956 (1).

For example, it has been said that the number of known tuberculosis cases is increasing. Some have speculated that home care has replaced hospital care. Our study does not support these views. Undoubtedly, caseloads in some health departments are heavier because they are now supervising significant inactive cases for longer periods of time. But, in every area, the study shows that there were fewer known clinically active cases than had been estimated previously. This agrees with case register reports from 30 States, which show that between January 1, 1953, and January 1, 1955, there was a 6 percent decline in the number of hospitalized cases whereas there had been a 12 percent decline in the number of active cases at home. In other words, the number of active

cases at home declined twice as rapidly as the number hospitalized.

While our study sought, in particular, information about active cases at home, we had to review several times as many cases which were carried by the local health departments as significant for public health supervision. Cases selected for the study consisted of all cases classified as clinically active and presumably active and also all cases for which drug therapy is prescribed even though many drug cases are classified as inactive, arrested, or probably inactive. The activity classification of tuberculosis cases at home is shown in the following table.

Classification	Number	Percent
Active -----	1,896	60
Presumably active-----	376	12
Inactive with drug therapy-----	887	28
Total -----	3,159	100

Those cases called "presumably active" consist chiefly of patients whose latest clinical diagnosis was "active" or "probably active" tuberculosis although this diagnosis was at least a year old at the time of the study. Also in the "presumably active" group are all cases classified as "arrested with positive bacteriological status." Technically, the 1950 Diagnostic Standards of the American Trudeau Society stated that arrested cases may, under specified conditions, have positive bacteriological findings. Actually, physicians seldom classified positive cases as arrested. In this study of more than 3,000 cases, only 70 cases were listed as arrested with positive bacteriological findings. Since these cases are of public health importance, they were included in this study. Incidentally, the small number of such cases found indicates the wisdom of eliminating this category from diagnostic standards.

History of Hospitalization

We have all wondered to what extent home care is replacing hospitalization or what proportion of tuberculosis patients have ever been hospitalized. Our study provides factual answers to these questions derived from the ex-

periences of more than 7,000 patients in the 37 areas. Several years ago (2a), we found that less than half of the known cases were hospitalized. This study reveals that more than half, or 56 percent, are hospitalized as of the census date and that most of the patients at home today have a history of hospitalization. Eighty-nine percent of the tuberculosis patients either were hospitalized or had been hospitalized (fig. 2). Thus, we are unable to demonstrate any marked trend toward substituting home care for hospitalization. We do recognize a very marked trend toward supplementing hospitalization with a substantial amount of chemotherapy at home.

Figure 2. Hospitalization history of tuberculosis cases.

While 56 percent of the known significant cases were hospitalized as of the census date, there was some variation from area to area, with the large cities having 61 percent of their patients hospitalized, and the nonmetropolitan areas, largely rural, having only 46 percent hospitalized. These percentages are shown:

	Percent
Cities 200,000 population and over.....	61
Metropolitan areas exclusive of large cities.....	52
Nonmetropolitan areas, largely rural.....	46

Thus, the areas with the fewest health department and clinical facilities have the lowest percentage of hospitalized patients and the highest percentage at home. An identical relationship exists for the proportion of patients who have been hospitalized at some time in the past: Large cities have the highest proportion ever hospitalized and rural areas the lowest. For each area except four small areas, three-quarters or more of the known patients either

Figure 3. Percentage of tuberculosis cases hospitalized, by age group.

were or had been hospitalized. This proportion of cases hospitalized has many interesting ramifications pertinent to tuberculosis control.

Age, Sex, and Race

Many tuberculosis hospital directors have said that the average age of their patients is increasing and that they now have many more older patients than in former years. Our study showed that, of those patients 65 years of age and over, a higher proportion are at home than of any other age group (fig. 3.) This difference by age was found to exist for women as well as for men and for rural areas as well as for urban. Because of the drop in newly reported cases in young people, the higher percentage of younger people hospitalized, and the higher proportion of reported cases in older age groups, we predict that the number of younger adults hospitalized will decline and that the number of older adults hospitalized will remain stationary, or in some instances, even increase.

Analysis of newly reported cases and deaths from tuberculosis have shown that more men have far advanced disease than do women and that the male death rate is more than twice the female death rate. With this knowledge, it was encouraging to find that a higher proportion of men than women are hospitalized (fig. 4). While reasonable success has been

Figure 4. Percentage of tuberculosis cases hospitalized, by sex.

achieved in getting men hospitalized, there has been less success in keeping them in the hospital. That is, of the men at home who had been hospitalized, almost half had been discharged against medical advice whereas of the women, less than 10 percent had been so discharged.

Nonwhite patients had a higher proportion of far advanced disease at the time of first report and also a higher death rate than white patients. Thus, it is also encouraging to learn that a higher proportion of nonwhite patients are hospitalized. Actually, only 51 percent of the white patients were hospitalized as of the census date while 64 percent of the nonwhite patients were hospitalized (fig. 5). This may be due in part to the fact that nonwhite patients, especially in the southern areas of the country, showed a slightly lower rate of leaving against medical advice than did white patients.

Figure 5. Percentage of tuberculosis cases hospitalized, by race.

These observations indicate that though we have tried to adapt hospitalization practices to meet the needs required by sex and race, we have not met needs in respect to age.

Diseases and Conditions

Tuberculosis patients at home had a wide range of diseases and conditions coexisting with tuberculosis. Slightly more than one-fourth of the patients had one or more coexisting diseases. In 6 percent, alcoholism coexisted with tuberculosis. Approximately 3 percent were recognized as having diabetes and a similar proportion as having cardiovascular disease.

Extent of Disease

Of the nonhospitalized cases in which the extent of disease was specified, almost half were far advanced as compared with 60 percent

Figure 6. Percentage of tuberculosis cases with far advanced disease.

far advanced on admission among the hospitalized cases (fig. 6). Each of these groups contains a substantially higher proportion of far advanced cases than the newly reported active cases. This we would expect because of the usual prompt response of minimal cases to therapy. The extent of disease was about the same for cases from rural areas, as compared with those from the large cities and suburbs.

Bacteriological Status

The seriousness of the tuberculosis problem is reflected by the infectiousness, or bacteriological status, of the cases. Based upon the best information available to health departments, clinics, and public health nurses supervising these cases, the item of first note is the fact that no bacteriological examinations were available for half of the active cases within the 6 months preceding the census date even though a very substantial proportion of these were positive when last examined (fig. 7). In addition, one-fourth of the active and presumably active cases were bacteriologically positive within 6 months of the study date. Comparatively few of the

Figure 7. Bacteriological status in last 6 months, active cases at home.

persons with unknown bacteriological status were newly reported cases; almost half had been known to the health department for 3 years or more. A slightly higher proportion of the positive sputum cases had been hospitalized than had the negative cases.

Supervision and Treatment

Several years ago (26), we pointed out that many health departments do not maintain current information about the supervision and activity classification of their cases. In this study, of those classified on the case register as clinically active cases at home, 35 to 40 percent were found to be dead, hospitalized, moved away, lost, or no longer active. Therefore, they were removed from the group of "known active cases at home." Then, a check on the activity of cases classified as "activity undetermined" and a search for cases from other records resulted in adding almost 10 percent to the "known active cases at home." We reassert that health departments frequently do not know about the current supervision and activity of their cases and do not maintain adequate case registers. This deficiency might well be considered by those who are contemplating the addition of a register for tuberculin reactors.

Even though a substantial portion of the cases were thus excluded, the remaining active and presumably active cases were not all under medical supervision. In fact, almost one-fourth were under no known medical supervision. Those under supervision were about equally divided between private physicians, health department clinics, and all other sources of supervision (fig. 8).

Figure 8. Medical supervision of active cases with supervision known.

In spite of this inadequate knowledge about tuberculosis patients, health departments have made progress in the supervision of cases. Large numbers of inactive and probably inactive as well as active cases are receiving drug therapy at home, and the administering of such treatment programs requires much more work per patient than formerly. Even though the number of active cases at home has decreased somewhat, health departments are generally expending more effort on tuberculosis control. In fact, one large city health department reports that one-third of all nursing visits were made for tuberculosis. This is understandable when one recognizes that streptomycin was given, either alone or in combination with other drugs, to two-thirds of all the patients on drug therapy.

Drug therapy was prescribed for less than half of the active and presumably active cases at home. In view of the widespread interest in giving drug therapy to patients at home, we hoped that this proportion would be much larger. The low ratio results from several factors: First, some physicians so firmly believe that active tuberculosis cases must be in a hospital that they will not prescribe drugs to non-hospitalized patients. Second, almost one-fourth of the active and presumably active cases are not under medical supervision. Third, in some areas, medical societies, health departments, and tuberculosis associations have not developed treatment services for patients who are unable to pay for private care.

As might be expected, the recent hospital discharges showed the highest proportion of patients who had drug therapy prescribed while those discharged for a longer period of time and those never hospitalized showed lower proportions.

We have used the phrase "drug therapy prescribed" quite deliberately because giving a prescription is not necessarily synonymous with the patient's actually taking the medicine. In fact, available information gave evidence that, of the patients with drug therapy prescribed, 12 percent were not fully following their prescriptions.

The active cases with drugs prescribed also

generally had bed rest recommended while, of those without drugs prescribed, less than half had bed rest recommended. The inactive and arrested cases with drug therapy were more likely to have rest prescribed than were the active cases without drug therapy.

Nursing Service

Our study confirms that there are more medical and public health nursing services available in cities and densely populated areas than in rural areas. Almost one-half of the population in rural areas had no readily available chest clinics; 10 percent had no public health nursing services. In the areas where nursing services are available, three-fourths of the population had 1 nurse serving more than 10,000 population; 8 percent had 1 nurse to more than 25,000 people. To bring nursing services to recommended standards would require more than a doubling of staffs. With few exceptions, the nurses carried a generalized public health nursing service.

Therefore, it is somewhat surprising to find that public health nurses had made home visits to 69 percent of the nonhospitalized tuberculosis patients during the 6 months preceding the study.

However, it is significant that one-third of the patients seen at home were visited only once during the 6-month period. This was true for both the active and presumably active cases and for those with inactive disease on chemotherapy. Seventeen percent of the patients were visited more than 10 times in 6 months.

	Percent
1 visit only.....	34
2-9 visits.....	49
10-154 visits.....	17
Total.....	100

For many years it has been recommended that high priority for nursing service be given to patients newly reported or recently discharged from the hospital. We found that practice quite consistently follows this policy for public health nursing. Visits had been made to three-fourths of the patients discharged from hos-

Figure 9. Percentage of cases visited by a public health nurse within last 6 months.

pitals within 6 months and to three-fourths of the new cases reported to health departments (fig. 9).

Let us consider the one-third of all study patients who received no public health nursing service at home. The majority of these persons were not considered in need of service. One-fourth had never been referred for service, and physicians requested no nursing service for 8 percent.

	Percent
Service not indicated.....	33
Never referred.....	28
Physician requested no visits.....	8
No service available.....	7
All other reasons.....	24
Total.....	100

Some of these patients were under the care of the hospital or sanatorium outpatient department. The largest percentage were under the care of private physicians. Almost 200 of the patients who were not visited at home had unknown medical supervision or none at all.

One of the most serious deficiencies of programs in general is the lack of referral of patients and the transfer of information between physicians, hospitals, laboratories, social agencies, and health departments. Many health departments do not query private physicians periodically to ascertain current diagnoses or to establish whether the patient is still under care. Frequently, reports of laboratory examinations are not sent to the public health nurses giving care to the patient. Many hospitals do not include in their reports to the health department

the diagnosis, sputum status, type of discharge, or recommendations for continued therapy. Many health departments do not know which patients are receiving help from social agencies, and frequently the social agencies do not know which patients in their caseloads have a tuberculosis problem. It is obvious that such practices as these result in disjointed and inadequate utilization of the community services available to patients and their families.

Social Aspects

Fairly widespread impressions have grown up that tuberculosis patients are predominantly social misfits, especially skidrow alcoholics. Because of the complexity of study of such matters, social data were collected only on certain basic factors such as marital status, family composition, major social problems.

Marital Status

More than half the patients in the study were married. This is approximately the same distribution as the United States census population of 1950. Thus, contrary to a common impression, tuberculosis is not just a problem of unattached men.

Composition of the Family

Of all active and presumably active cases at home, about 20 percent of the patients have children in the home under 5 years old. About half of the families with small children in the home have 2 or more children in this age group. Almost half of the patients at home did not have a room alone.

It is not necessary to elaborate on the obvious public health import of these findings. Because of the frequent report of problems in family relationships as well as financial and other social problems, we assume that some of these homes were not ideal settings for recovery. Criteria for homes suitable for treatment of patients with active tuberculosis have not been adequately developed. Furthermore, the very small proportion of patients receiving the broad services of organized home care programs indicates the need for a more extensive investiga-

tion and careful evaluation of the social situation of nonhospitalized tuberculosis patients.

Social Problems

About 46 percent of the patients on home care were reported as having major social problems.

	Percent
Practical needs.....	21
Emotional needs	25
Unreported.....	15
No major problems.....	39
Total.....	100

The types of problems fell into two broad categories: (a) such practical matters as insufficient income or inadequate housing, and (b) emotional areas relating to the patient's reactions to his illness and relationships between members of his family. The cases were almost equally divided according to these major types; however, there were a number of instances in which multiple problems existed.

Most of the patients who left against medical advice were included in the category of patients with social problems. We believe that for a large number of the patients who gave personal preference as the predominating reason for their rejection of hospitalization, social problems underlay their resistance.

The extent to which patients were receiving social service was analyzed. Of those patients reported as having a social problem, over 60 percent were not receiving social services of any type.

	Percent
No service.....	62
Public welfare.....	20
All other agencies.....	14
Unknown.....	4
Total.....	100

Approximately 20 percent had received service from a department of public welfare. The remaining 18 percent received service from other agencies and from medical social workers in health departments. Only 17 percent of the patients at home were receiving financial assistance from any agency. Generally, public assistance did not include grants for medical

costs since most social agencies consider the care of tuberculosis to be the responsibility of medical and public health agencies. Financial problems were often encountered in relation to the costs of medical care, especially the purchase of drugs when these are not provided free.

The majority of the patients and families who were being helped financially were receiving assistance from public welfare agencies. Some welfare departments consider the determination of eligibility and the provision of grants to be their full responsibility. Even when these agencies accept a broader responsibility, lack of trained staff and the usually large caseloads often limit the extent to which they provide casework services.

The greatest concentration of social agencies was found in metropolitan areas. However, it was of particular interest to discover that 80 percent of the study population in rural areas had no social services except for those provided by departments of public welfare.

Alcoholism

Special attention was paid to the extent of alcoholism among the nonhospitalized patients since this condition is generally considered an important factor in tuberculosis. The term "alcoholism" was listed by health department staff for patients whose drinking habits were considered a problem by the patient, the family, or the community. In only 6 percent of cases was alcoholism reported as a coexisting disease.

Approximately 11 percent of the men over 35 years were classified as alcoholic. Although the percentage of married persons classified as alcoholic is lower than that of either the single, separated, divorced, or widowed patients, the number of married alcoholic patients was largest since the majority of study cases were married. Nearly all of the patients designated as alcoholics had been hospitalized, but three-fourths left against medical advice. The public health implications are apparent.

We recognize the possibility that some of the hospitalized alcoholics may leave the sanatorium and disappear and thus not be available

for counting in our study. However, a similar low proportion has been found in other recent studies made by the Public Health Service Tuberculosis Program. Even so, we also recognize the importance of this problem in the individual patient.

Conclusions

Our study of unhospitalized tuberculosis patients shows that they are, in most respects, quite like other people. Probably the one most important result that the study points out is the serious limitations of tuberculosis programs for the care and supervision of known cases. Consequently, it gives us a guide for the improvement of these programs.

If we believe it is important to tuberculosis control to have precise, current information about tuberculosis patients who are in need of intensive care and supervision, and if we believe that adequate treatment of these patients determines, to a large extent, the effectiveness of disease prevention and control, the study findings disabuse us of complacency.

More specifically, the study delineates certain definite areas of action in which improvements must be made.

1. Precise information must be maintained about the current medical and social status of tuberculosis patients, their families, and their environment.

2. Health departments must summarize such current information to evaluate tuberculosis control problems and to plan programs on the basis of local needs.

3. Closely integrated service programs must be provided for diagnosis, treatment, social service, and public health supervision of patients.

4. To this end, efficient communication and exchange of information are required of health departments, private physicians, laboratories, hospitals, clinics, and other groups and agencies.

5. While private physicians need education and consultation on the techniques of diagnosis and treatment, there is an equal need for obtaining their understanding of the importance

of public health supervision for patients under their care.

6. Standards for selection of patients to be treated at home and in hospitals should be established, based on patients' needs and services available locally.

In closing, we feel that the study has succeeded in confirming, replacing, and reversing many generalizations concerning tuberculosis.

We have tried to point the way to future action in the community.

The Social Significance of Chronic Illness

By LUCILLE M. SMITH

EVERY PATIENT with tuberculosis, like every patient with a long-term illness, has one need which overrides all others: to be looked upon as an individual, a whole person—not a disease or a stage of a disease or the focus of a program. And his identification as a person must, of course, be specifically related to his family and to the community of which he has been and is a part.

Other needs of care arise from the nature of the illness as distinguished from the characteristics of the individual. Tuberculosis, although still essentially a chronic disease, combines some of the patterns of both acute and chronic illness. The new therapies have introduced some possibilities for fairly rapid changes in the

patient's physical status; he now may experience marked improvement in weeks instead of years. Yet, exacerbations and remissions may occur, and treatment must be modified accordingly. Thus, the patient's reactions and responses to his condition are likely to be in a state of flux, and the care he receives must accommodate to this flux.

How extensive is the variety of services that long-term patients require? A committee at the 1954 National Conference on Care of the *Long-Term Patient* listed 30 needs, several, or even all, of which a long-term patient will require while at home, or while in a hospital or some other type of institution. This list shows not only the complexity of the patient's needs but the formidable problem of community organization required to assure ready availability of the service indicated (see inset).

We need to appreciate fully that the entire problem of long-term care is not a collection of separate problems to be solved one by one in simple progression. For the community, as for the individual, long-term illness presents a complex of needs so interrelated that many require simultaneous attention. And simultaneous attention is possible only if the

Mrs. Smith, chief, Health Services Organization Branch, Division of Public Health Methods, Public Health Service, presented this paper at the annual meeting of the National Tuberculosis Association in New York City, May 23, 1956. Extensive use has been made of an analysis of the major elements in long-term care from chapter 1 of "Care of the Long-Term Patient," a report of the Commission on Chronic Illness to be published shortly.

30 Needs of Long-Term Patients

Medical supervision	Sheltered work, at home or elsewhere
Drug and diet therapy	Personal adjustment training
X-ray therapy	Homemaker service
Surgery	Transportation
Psychiatric treatment	Financial aid
Rehabilitation	Assistance in obtaining adequate housing
Dental treatment	Foster home care
Social service	Legal aid
Bedside nursing	Convalescent care under medical supervision
Physical therapy	Custodial care
Appliances	Counseling to modify the family's and the patient's attitude toward chronic illness
Training in the use of appliances	Friendly visitors or volunteer corps
Occupational therapy	
Training in self-care	
Vocational counseling	
Education	
Religious opportunities	
Vocational training	

major elements of the problem are widely recognized and their relationship understood.

Elements of Long-Term Care

First of all, there is the relationship of tuberculosis and general medical care: Each requires integration with the other. Second, rehabilitation must be incorporated within all phases of care. Third, we must genuinely ask ourselves: Is institutionalization the primary solution to the problem? The fourth major element concerns mental health: How can we refocus the objectives of both tuberculosis and mental institutions so that adequate mental health services are available in tuberculosis hospitals and adequate care for tuberculosis in mental hospitals? Fifth, how can we improve and extend present, and develop new, means of financing long-term care? The sixth element is that of increasing the numbers of trained personnel and improving the quality of their training. Seventh, every community, and local, State, and national health and welfare organization needs to improve ways to coordinate facilities and services for tuberculosis patients. Eighth, there is need of accelerating improve-

ments in attitudes toward tuberculosis, and, indeed, toward all long-term illness. Finally, broad measures are needed to produce additional facts on the extent of the problem and the utilization of medical care resources for long-term care.

Integration With General Medical Care

Medical care has been geared to short-term illness except in special facilities devoted to particular categories of long-term illness, such as tuberculosis.

A general hospital, for example, is likely to operate at a tempo primarily designed for emergencies, a tempo quite unsuited to the chronically ill. Further, professional interest tends to gravitate to the acutely ill except in hospitals with a well-rounded and active teaching program. Attention to the nonacute phases of chronic illness is inclined to be transient and minimal, and professional services to the long-term patient are often meager. In the past, this has resulted in the all too familiar practice of excluding tuberculosis patients from general hospitals. Sometimes, unhappily, it has resulted in substandard tuberculosis care in those few general hospitals which do accept such patients.

But one should not assume that neglect of long-term illness will be corrected by further separation of the long-term patient from general medical care. On the contrary, prevention and care of chronic ills should be an integral part of general medical care.

An encouraging move in this direction is the slowly developing program for routine chest X-rays of all persons admitted to general hospitals. About 24 percent of all general hospitals have such programs, according to reports to the American Hospital Association for 1954 (1). If this program is used to detect early tuberculosis among persons not yet aware of symptoms, it will be a valuable means of integrating general and long-term care. If, however, the program is used to expedite the transfer from the general hospital of all patients

newly discovered to have tuberculosis, it will serve further to separate the two.

Rehabilitation

Failures with regard to rehabilitation are of two kinds.

Few think of rehabilitation as an integral part of care. Few discern its important implications for prevention. Rather, it is conceived of as a definitive action to be tacked on at the end of definitive medical care.

Moreover, many people think that rehabilitation is necessarily expensive, that it calls for the elaborate equipment and specially trained personnel of the rehabilitation center. For some patients, to be sure, it is. But such outstanding authorities as Rusk and Kessler repeatedly assert that much rehabilitation is accomplished by simple methods—methods based on an understanding of man's emotional make-up. Nevertheless, it is still commonplace for a patient with tuberculosis to be hurried into a sanatorium before satisfactory plans are made for the support of his wife and children, before he has been assured that his family has not contracted the disease, before he has had fully explained to him what his regimen is to be.

Suppose his disease is discovered in an occupational health survey in a factory where he has just got a job after a long period of unemployment. Probably he will resist violently an abrupt recommendation that he be hospitalized. If he has recently been promoted, or had some other long overdue good fortune, he will need time to become accustomed to the idea that he is in trouble.

If he enters the institution and finds that it has rigid and arbitrary visiting hours and that he has arrived just after one of them, he may suffer unnecessary anguish before he can see his wife again. Such incidents typify unnecessary hazards to restoration of his health.

These incidents represent not so much failure on the part of individual providers of health services, but faulty policy—in the welfare or health department, the factory, the hospital. They point up neglect of rehabilitation possibilities per se. They demonstrate failure to

recognize that rehabilitation can prevent further deterioration; that proper preventive measures often obviate the need for rehabilitation and reduce the need for treatment; that prevention, care, and rehabilitation are inseparably intertwined.

Home Care Services

Institutional care as the solution to long-term care problems has long been overemphasized. Even though less than one-fourth of our long-term patients are in hospitals and other medical institutions, many who are in such places could be cared for as well or better at home. Construction of some additional medical treatment facilities is still needed, particularly for patients needing rehabilitative services and those whose need is primarily for skilled nursing care. But more and more beds for long-term care will not provide the care needed.

Private practitioners and administrators of general, tuberculosis, chronic, and mental hospitals verify this fact: There are in institutions large numbers of patients whose requirements for care could be better met in the home, if nursing and other services could be made easily available to them—a Gatch bed for the tuberculosis patient; someone to give him an intramuscular drug; someone to help him in and out of bed occasionally; someone to shop for the housewife with tuberculosis.

The story is repeated over and over. As soon as one important need of the patient develops that the family cannot meet, he is placed in a hospital or in some other institution, and then what happens? Once the admission occurs, his place in the home may be lost forever. The doctor and social worker who later try to help the patient and his family plan for his return find that the readjustments he must make are insuperable.

Home care is one antidote to overinstitutionalization. One of the most constructive steps a community can take is providing a generous measure of the services which will enable families to care for their own at home. Each community will need to determine for itself what services should be offered and by whom. The

most frequent and perhaps the most important service is that of the visiting nurse, providing bedside care. Other important home services would include social casework, physical and occupational therapy, homemaker service, friendly visitors, and the loan of wheelchairs, hospital beds, and bedside equipment. These services may or may not be integrated into a fully organized home care program; but if the services are easily available, if administrative obstacles to their use can be removed through skillful community organization and, if practitioners of medicine are fully informed about these services and will in fact make full use of them, then the community can make substantial progress in preventing unnecessary and unwise institutionalization.

A word of caution is indicated concerning the concept of home care. This phrase to some means simply care at home for the nonhospitalized tuberculosis patient. To others it means something more comprehensive, such as "organized programs having centralized responsibility for the administration and coordination of services to patients and for providing the minimum of medical, nursing, and social services, and essential drugs and supplies" (2a). Both kinds of home care have their place in a community. Of 11 organized home care programs in the study made by the Public Health Service and the Commission on Chronic Illness (2b), patients with tuberculosis were under care in 5.

Example of Good Home Care

The following case shows how a good home care program, administered by a general hospital under Jewish auspices in a large midwestern city, has served a patient with tuberculosis.

Following X-ray examination in a mobile unit, Mrs. A., age 33, was told she had active pulmonary tuberculosis. The public health nurse in her followup visits was met with denial of the diagnosis. Mrs. A. adamantly refused to consider the necessity for care in a State sanatorium 240 miles away from home. Finally, she consented to discuss the possibilities

for care in the home care program of a private general hospital.

In discussion with the home care social worker, Mrs. A. continued to deny the diagnosis of tuberculosis. At the same time, however, she expressed her dual fears of infecting her young adopted sons, ages 5 and 7, if she remained near them, or of crippling them psychologically if she left them for an extended period for medical care.

Mrs. A. is an intelligent person of broad interests, a highly skilled commercial artist, whose primary interest is her family. She had experienced many complications in achieving the adoption of her two sons, brothers who had previously been in several homes. These youngsters had barely acquired a degree of security with their adopted parents. Mrs. A.'s husband, an auditor, had a position which often kept him away from home except for weekends. Their income was about \$5,000 a year. They were buying a 4-bedroom home in a suburb.

With trepidation, Mrs. A. decided to risk intensive study in the general hospital to see if she could be attended properly in the home care program. A 10-day study in the hospital revealed far advanced tuberculosis with cavitation in the left upper lobe. Sputum was positive. Treatment requirements included: regular medical supervision; complete bed rest in a room to herself with bathroom privileges; isolation, for example, no visitors in her bedroom; relief from all household responsibilities; and most important, full cooperation of the patient in following these requirements.

In this home care program, the medical chief, after staff conference, makes final judgment on the willingness and ability of his patient to give full cooperation. After much discussion with Mrs. A., he decided that she wanted to and would follow his recommendations at home.

The social worker with the family had found that Mr. A. and the children believed that they could live with Mrs. A. and help her follow medical recommendations. Physical arrangements in the home were excellent. A full-time homemaker—capable of managing both the household and the two children—was found to live in. The visiting nurse could reinforce

with home teaching the doctor's instructions. The social worker would visit regularly and be on call. The home care doctor would pay periodic visits to the home.

This patient went home from the hospital on October 1, 1954. The children had a small dining table in the hall outside her room. They had their meals at the same time she did. Their chairs were always in the same place for short periods of conversation. Her quiet periods coincided with their school hours and bedtime.

This was a limited type of life for a vital woman such as Mrs. A. By spring, she longed for her usual garden activities and friends. Her doctor began to authorize graduated activities. For example, she was permitted to have tea with some of her neighbors, who sat in the yard outside her window while she remained in her bed.

By August 1955, Mrs. A.'s sputum was negative. By November 1955, she was readmitted to the general hospital for chest surgery. A left upper lobectomy was performed. She continued to make excellent progress and in May 1956 was discharged from the home care program.

The strength and unity of this family have been greatly protected and preserved in this period of grave illness. Even so, the two children, as well as Mrs. A., are now overconscious of health. The children show some fear for their mother's health. She in turn does more for them at this time than most 8- and 10-year-olds need. The social worker in the home care program will continue to work with Mrs. A. to aid in her efforts to reach a better balance in helping her children achieve normal growth to independence.

For those who may be moved to explore the possibility of a home care program in their own communities, guidelines for establishing such programs are published by the Public Health Service and the Commission on Chronic Illness (2b).

Mental Health

While prodigious sums are spent for maintenance of mental patients, comparatively little is spent on treatment and study of mental illness.

Many patients with a primary diagnosis, such as tuberculosis, also suffer mental illness. In fact, sooner or later most long-term patients develop emotional afflictions. In short, mental illness permeates the entire field of chronic illness. In mental hospitals there is too little treatment of tuberculosis; in tuberculosis hospitals, too little emphasis on psychiatric care. The major need for improving this situation is a vast increase in community mental health services and an overhaul of mental institutional services with an active program of therapy as the core of the program. Improvements in comprehensive care for tuberculosis patients also will moderate many of their mental stresses.

Money

The financing of care for tuberculosis presents a paradox. Not enough money is being devoted to such care; yet a considerable portion of that which is spent is not used effectively. As the Commission on Chronic Illness says in its report, *Care of the Long-Term Patient (3a)*: "Because of inertia, outmoded practices persist; because of timidity, measures demonstrated to be practical in some communities are slow to spread to others; because of frugality, approaches are adopted that prove to be 'penny-wise and pound-foolish'; because of vested interests, the status quo is maintained when a fairly thoroughgoing realignment of methods of providing and financing services would be more economical. . . .

"As voluntary health insurance continues to grow, more money will be available for the care of those who can afford to pay the basic premiums. Trends are in the direction of extending coverage and modifying policies in ways that will benefit the long-term patient; but large groups of these patients are still excluded from the bulk of private insurance and from nonprofit voluntary prepayment plans."

The limitation of insurance on preexisting conditions is one example of an exclusion that adversely affects the patient with tuberculosis; another is the common 120-day limitation on hospital care.

"Government funds are frequently held to a parsimonious level, reflecting the traditional philosophy of providing minimum subsistence and care rather than reconstruction of the health of the person. All too often public monies are made available in ways that practically preclude their more effective use. The manner in which they can be spent may be so restricted by law that they can pay for some services but not necessarily the kind of service the patient needs. Government often waits until the patient is reduced to the level of public assistance, missing earlier opportunities to halt the deterioration of his health. This in spite of the fact that many programs which are adequately supported are demonstrating good results" (3b).

Although private charities cannot carry a major share of the operating costs of care of the long-term patient, their use of "venture" capital has been a unique contribution in developing counseling services, homemaker services, and home care programs. Such pilot demonstrations may be used to muster a greater degree of public support.

Personnel

For long-term care, probably the most serious personnel needs are: general practitioners; psychiatrists; specialists in pulmonary medicine and in physical medicine and rehabilitation; public health physicians; nurses, particularly the public health nurse giving bedside care and the practical nurse; trained attendants; medical and psychiatric social workers; occupational, physical, and speech therapists; and vocational counselors. Most of these shortages are not due primarily to insufficient capacity of professional schools. The schools which offer training for most types of the needed personnel report a lack of students.

A few facts on the availability of one class of needed personnel—the medical social worker—will suffice to illustrate the seriousness of these shortages. These facts are available from a joint study by three organizations: the American Hospital Association; the medical social work section of the National Association

of Social Workers; and the Public Health Service. It is to be published this fall.

One in every three hospitals for tuberculosis and other long-term patients has a social service department, but only 1 in 8 hospitals for short-term patients. Perhaps, for long-term patients this sounds reassuring. Nevertheless, the sober fact remains that 65 percent of the 410 tuberculosis hospitals have no social worker; 24 percent have only 1 worker; and only 7 percent have more than 3 social workers.

Considerably more patients receive social services in tuberculosis hospitals than in general hospitals. But even in the tuberculosis hospitals, only 35 percent of those in hospitals with social service departments receive this type of service; these amount to 20 percent of patients in all tuberculosis hospitals.

The proportion of graduate social service personnel is somewhat less in tuberculosis hospitals, 60 percent, as compared with 62 percent in general hospitals for short-term patients, and 73 percent in general hospitals for long-term patients.

Other findings suggest that social service departments in tuberculosis hospitals may not be as well integrated with other departments as are departments in general short-term and long-term hospitals. Conspicuous contrasts are shown by the participation of social work departments in such activities as meeting with hospital administrators and ward rounds. Seventy-one percent of the departments in tuberculosis hospitals had met with the hospital administrator, as contrasted with 90 percent in general long-term hospitals. On ward rounds: 27 percent of the departments in tuberculosis hospitals had participated in ward rounds, as contrasted with 62 percent in general long-term hospitals. Twenty-eight percent of the departments in tuberculosis hospitals make no reports to the hospital administrator as compared with 7 percent of each of the other types of hospitals.

With respect to specialty consultations, the proportion of departments having psychiatric and other medical specialty consultations is substantially smaller in tuberculosis hospitals than in the other types of hospitals.

These findings suggest the desirability of special efforts by voluntary and official agencies to strengthen existing administrative relationships through such measures as special studies, consultation, and institutes. The need for additional scholarship aid for both the first and second year of graduate training is equally obvious if the tuberculosis hospitals are to be adequately supplied with graduate social work staff.

Not only must the numbers of most health personnel be increased, but educational programs must be refocused to produce personnel who will be interested in and equipped to care for long-term illness. Education for most of these professions traditionally has been directed to acute illness and has been provided principally in a hospital setting. Interest and skill in serving patients at home need primary emphasis.

Coordination of Services

Lack of coordination of services in some communities is greater than the lack of money. One cannot overemphasize the importance of good working relationships among diverse community agencies, facilities, and interests.

In recent years a promising start in coordination and integration has been made in many localities.

In a few scattered communities—Essex County, New Jersey; Chicago; Milwaukee; and San Francisco, for example—central services for the chronically ill have been established under voluntary auspices to advise patients, their families, and physicians on where various types of counseling and referral service can be obtained. People can be helped to examine various solutions for their problem, learn what and where various services are available, what they are likely to cost, and which services are available without charge or on a part-pay basis.

A single source of these counseling and referral services, however, is most unusual. Most victims of long-term illness must attempt to make contacts with a vast number of programs, agencies, and institutions before they can locate the specific service needed at a given time

and, if the cost is beyond their means, find a source of funds with which to pay.

Local tuberculosis associations can do much to help establish similar services in other communities. We have only begun to tap the possibility of joint financing by the voluntary health agencies of much needed community services, of which counseling and referral are but one example.

Another type of coordination is that which is possible nationally. The experience of the Commission on Chronic Illness is a notable example. Born of the wish of four national professional associations and the Public Health Service to make order out of various unrelated efforts to improve long-term care, the commission has concluded its brief but highly successful career. It is gratifying to see some of the forecasts of things to come. The American Medical Association, for instance, is now publishing the *Chronic Illness News Letter*, in connection with which it will also serve as an information center for the many inquiries which the *News Letter* stimulates.

A committee has been appointed to develop a program of research and education relating to the aging processes. This committee has already begun plans with the Public Health Service for ways to bring together State medical societies and State health departments on projects to improve the health of older people. Still another committee is reviewing the progress being made by the voluntary prepayment plans in extending coverage to the long-term patient.

In the field of rehabilitation, the American Medical Association has recently created an intra-association group, consisting of representatives of several of its councils, to look into the present status of rehabilitation, review existing programs and procedures, and suggest methods for improvement and coordination. Field work by the Council on Medical Service is already underway.

The American Hospital Association meanwhile has appointed a Committee on Chronic Illness in its Council on Professional Practice. The committee plans to publish new materials to (a) further accentuate the vital role of rehabilitation, (b) answer how-to-do-it questions

including those of financing the hospital care of the chronically ill, and (c) show examples of good programs in action.

The American Public Health Association and the American Public Welfare Association likewise are projecting programs in which the major objective is to achieve coordination of services and facilities—in itself an example of coordination.

Attitudes

Attitudes toward long-term illness, warped for generations, are changing as its nature and the needs of its victims become understood and as methods of treatment are learned. Neglect and pessimism are being replaced by an aroused social conscience and by confidence in the value of treatment and rehabilitation. The change is not sufficiently rapid or extensive, of course, and it needs to be accelerated among persons in the health professions even more than among those in the general population.

In the past, misconceptions constituted the single most important block to changing attitudes. Because much long-term illness is painful, ugly, depressing, and costly, it is still a major feat to gain attention and a constructive attitude for its victims.

Nevertheless, negative ideas have yielded. Long-term illness is no longer commonly regarded as hopeless and the care of the long-term patient is becoming a successful undertaking.

Need for Additional Facts

The final major element in the community's chronic illness program, the need for additional facts, should be first. Although most families are affected by it, we have no accurate up-to-date measure of the dimensions and various characteristics of long-term illness. Considerable research is being conducted on causes of the various chronic diseases and better measures for treatment, but little attention is given to studies of how best to apply what knowledge we already have.

Since 1949, the United States National Committee on Vital and Health Statistics has emphasized the need for more adequate informa-

tion on illness. In 1953 that group published a blueprint of the needs for statistics on illness in the general population (4). In addition to a few community studies, the Federal Government is now about to undertake a continuing health survey. Data collected on a sampling method will provide periodic estimates for the country as a whole and by regions on the prevalence and incidence of the major categories of sickness and disability.

The information obtained will include for each major disease and type of impairment "such things as number, age, sex, occupation of persons afflicted, the duration of disability, the amounts and types of medical or other services received for, or because of, the illness or disability, and ability to work or engage in other activities, for example, the ability to attend school in the case of a child, or, in the case of a housewife, ability to perform usual household duties" (5).

These surveys will provide facts much needed to comprehend the problem of chronic illness and to give direction to community plans for its solution.

relationships between a patient and a member of the ward staff, conflicts between one member of the staff and one or more of the ward personnel can influence, adversely or positively, the individual's course of treatment in the hospital. The death of another patient, a fluctuation in the physician's level of interest, the waxing and waning in the intensity of nursing care are described as significant contributors to stress.

Other studies support the premise that factors within the hospital setting contribute significantly to unauthorized discharges. One analysis indicated that two-fifths of the patients who left did so mainly because of such factors. Predominating among reasons given for leaving were dissatisfaction with medical treatment, hospital rules and procedures, and with the attitude and amount of interest shown by hospital personnel. Next in order were lack of facilities or concern for treatment of other ailments, conflicting medical opinions, and the physician's refusal to discuss the patient's condition with him.

Coleman, writing in the *Journal of the American Public Health Association* (July 1955), observed that though some few tuberculous patients can only be helped by psychotherapy, the majority can be helped by psychiatrically oriented physicians, nurses, and social workers. To these statements I would add my own conviction, notwithstanding the importance of specialized training, that the personal qualities of sympathy, objectivity, courtesy, and warmth are primary requisites for a professional worker.

The foregoing comments may be summarized as follows:

1. Granted that personality or social problems may lead to a patient's refusal to follow medical advice, we must not overlook the possibility of other contributing factors. These are primarily attitudes of hospital personnel toward patients and the willingness of such personnel to adapt administrative procedures to the needs of the patients. Flexibility or change is not always possible immediately, but professional personnel sometimes forget that institutions are for the patients, not structures in which the patient is only an incidental entity.

2. Responsibility for the welfare of the patient is shared by all persons in the hospital and by others on the outside. Some emotional outbursts may be expected to occur at any stage in any long-term illness. We cannot always avoid such outbursts. We should, however, in addition to providing the best of medical care, direct our efforts toward understanding the patient, being alert to possible pressures, trying to relieve the pressures before they become critical, providing an outlet for the expression of feelings without fear of recrimination, helping him directly or indirectly in resolving difficulties which create concern, and providing in general a comfortable atmosphere in which he can recuperate.

The Patient at Home

Before discussing ways of helping the patient who refuses hospitalization, let us face the fact that the controversy among medical authorities over whether a patient with active tuberculosis belongs at home or in a hospital has undoubtedly reached the patients. It is not surprising that they are confused about the importance of institutional care. The impressions of professional people working with the tuberculous patient are that he may resist hospitalization because he believes it no longer necessary.

Not to pursue this subject further, I shall cite two experiences which independently led to the same conclusion although they occurred several thousand miles apart and involved workers who were never in communication with each other.

Fifty recalcitrant patients were referred to a medical social worker in one health department and 50 to a sanitarian in another, to determine how these departments could persuade patients to accept the hospitalization they had refused. Both workers concluded that only 2 or 3 of the patients were genuinely recalcitrant. The remainder responded to the genuine interest displayed and help received. The 47 or 48 patients who subsequently accepted hospitalization voluntarily represented as many different situations and were alike only in that they were not actually recalcitrant. It follows then that we often label patients resistant when they

Patients Who Disregard Medical Recommendations

The tuberculosis patient who refuses to follow medical advice is a subject of major concern. It is frequently assumed that "uncooperative" patients are of certain prototypes and that the unattached, transient, male alcoholic is the most numerous. Another widespread assumption is that most nonconforming patients are inadequate personalities who react as they do because of economic and social pressures. Compulsory isolation is often considered to be the only effective method of management.

Though some aspects of this problem—primarily, why patients leave hospitals against medical advice—have received intensive study, relatively little research has been directed to learning why other patients with similar circumstances are willing to accept hospitalization; to determining whether patients at home follow medical instructions; or to developing means of helping patients who refuse to stay in the hospital. The various research projects completed in recent years have at least provided some knowledge which bears upon current assumptions and which suggests ways of helping the problem patient.

One major finding is that there is no predominating type of recalcitrant any more than there is a predominating cause for his behavior. Resistance to restricted activity, to medical authority, to isolation from family and social contacts, as well as fear of boredom, are normal responses in an individual accustomed to controlling his own destiny.

Some patients may acquiesce for a long time only to rebel in a crisis. Others may deliberately break discipline because they project their

hostility toward tuberculosis onto the hospital or society. Most have plenty of time to brood over their worries. The patient who has two diseases, alcoholism and tuberculosis, and the really mentally or emotionally disturbed patient who requires psychiatric as well as medical treatment, add to the complexity of the pattern.

The first step for devising ways of helping patients who do not follow medical recommendations is to identify the contributing factors. A further implication is that the method of helping must be adapted to the special needs of each individual.

My comments will be directed to a discussion of patients who leave the hospital against advice and patients who resist entering. Other forms of resistance, both in and out of the hospital, include refusal to permit surgery, failure to follow orders for restricted activity, evasion of medical supervision, working without medical approval, and refusal to take drugs. The same principles apply in all of these problems.

The Patient in the Hospital

Some research projects describe a method of predicting potential discharges against medical advice, and psychologists have concluded that these patients can be helped if kept under close surveillance. My own feeling is that any patient is a potential recalcitrant under circumstances of stress. Hospital patients react to stress situations more vigorously than they would to similar stimuli outside the institution. Society must help the tuberculosis patient withstand the pressures to which he is subjected, for the sake of his own recovery as well as for the protection of those he might infect. Its responsibility for protecting him against needless irritations is even greater. On occasion, hospital and health personnel unwittingly contribute to the many pressures which may push the individual beyond his powers of endurance.

Higgins and Kaplan in the *Journal of the American Medical Association* (May 1953) shattered some of the illusions about the hospital as a place of refuge and security. Their study showed that relationships among patients,

By Ruth B. Taylor, M.A., chief medical social consultant, Tuberculosis Program, Division of Special Health Services, Public Health Service.

health gains. There must be a willingness to find ways of adapting such practices imaginatively. Insistence upon conformity to a preconceived set of standards may only thwart all other efforts. Respect for the individual and his right to be different is fundamental in all social relationships, and especially when the individual is a tuberculosis patient.

Pulmonary Nodules Found In Cleveland Survey

To provide accurate rates on the frequency with which malignancy is found among solitary nodules in the lung parenchyma, a study was made of 666 persons in the Cleveland 1949 chest survey whose X-ray film revealed a nodule that was roughly spherical or lobulated in shape, fairly well circumscribed, at least 1 cm. in one diameter, and not obviously calcified. In the mass survey 673,218 chest X-rays were taken.

Followup, which included pertinent interval history and further X-rays, began 5 years after the survey, in March 1954, and continued through June 1955. Only 3.3 percent were of completely unknown status at the end of the observation period. The average followup time for those with complete followup was 5 years and 3 months.

By Sabine M. Holin, M.D., clinic physician, East Side County Clinic, Cleveland, Ohio; Ralph E. Dwork, M.D., M.P.H., director of health, Ohio State Health Department; Stanley Glaser, statistician, Tuberculosis Program, Public Health Service, Washington, D. C., Arthur E. Rikli, M.D., M.P.H., chief, Special Health Services, Public Health Service, Chicago regional office; and Joseph B. Stocklen, M.D., controller of tuberculosis for Cuyahoga County, Cleveland.

Nodules occurred $5\frac{1}{2}$ times more frequently among older persons aged 55-64 (about age 60) than in persons aged 25-34 (about age 30) and more often in white than in nonwhite persons. Among women the frequency rate was 0.87 per 1,000. The male rate of 1.12 was 30 percent higher. Neither the race or sex differences are due to age distribution of the population. Response to the X-ray survey was poorer among the older age groups in 1949 than among the younger age groups, but even if the response had been better and the study had included more persons, there is no reason to believe that the age-specific nodule frequency rate would have been different.

In 85.4 percent of the study population, no definite diagnosis had been established at the end of 5 years. Only 3.0 percent of the nodules were proved malignant, and 9.0 percent were proved to be or very probably were of tuberculous etiology; 2.6 percent of the patients had lesions of other etiology. No diagnosis, not even a suspected diagnosis, was made in 74.7 percent of the patients with nodules. However, in 10.7 percent, tuberculosis and cancer were presumed, and it seemed quite likely that malignancy may develop in a certain number of nodules of unproved etiology. Most of the nodules were diagnosed early.

No malignancies occurred in patients under 45 years of age. In all, there were 19 cases of cancer and 1 of Hodgkin's disease. Sixteen patients were male and 4 were female. Pulmonary resection was performed in 7 patients with cancer. Three of the seven were alive at the end of the study. Definite or probable calcification was found in 181 nodules, but none of these proved to be malignant. None of these nodules had appeared on the original film. Even if the persons least likely to have malignant nodules are excluded from consideration, the cancer rate is only 9.9 percent (see table).

The shape of the nodule appeared to have no prognostic significance, but the size appeared to be of considerable importance. In 43 persons the nodules were 4 cm. in size or larger; 10 of the 43 were subsequently shown to have malignancy. Roughly half of the malignancies were in persons with the larger nodule, and in

simply need more, or better, or different types of help in understanding and accepting medical recommendations.

Many dedicated health personnel have expressed feelings of frustration about the problems presented by patients who will not follow medical recommendations. They may pass more stringent laws. They may work with the courts to insure that forcible hospitalization will be approved when cases come up for consideration. They may withhold drugs or clinic services. They may develop locked wards or jail facilities. And they may use, sometimes reluctantly, all of the authority vested in their positions to protect the public health. Because the majority of patients in direct contact with health departments are in the lowest economic stratum, the impression has grown that the tuberculous belong to the socially inadequate segment of society. A corollary appears to be that they must therefore be handled by authoritative means. There are certain dangers inherent in this philosophy. To the extent that we stigmatize and use coercion on patients, the more likely they are to "go underground."

Actually, our studies have revealed an insignificant proportion of any predominating type of tuberculous patients, recalcitrants or otherwise. There are, of course, cases in which force alone seems indicated. Some psychiatrists believe that patients who are at odds with society can best be helped by authoritative, nonpunitive handling and that such patients receive real benefit from isolation in a facility especially adapted to their particular needs. Many an intractable alcoholic who has walked out of numerous hospitals responds to enforced treatment when it is tempered with sympathetic attention and the full gamut of psychiatric, social, and rehabilitation services.

Undoubtedly, we already have most of the answers to this problem of interpersonal relationships between patients and staff. The hiatus is between knowledge and its application. Since no two patients and no two situations are really alike, generalizations are often dangerous. Even so, I shall make a few generalizations in conclusion.

1. One might well expand Tollen's remark that "the prevention of irregular discharge begins at the start of treatment," and say that the prevention of resistance to medical recommendations begins early in the patient's life. However, because human nature has the capacity to change, each new experience can be positive or negative in its impact, and even well-adjusted people are not immune to overwhelming pressures. Those who have certain emotional inadequacies can also be helped through a crisis situation. When tuberculosis is suspected, an opportunity is present for influencing the patient's attitudes by the way in which his condition is interpreted to him. As he progresses through medical treatment, each new situation either facilitates or hinders the adjustment according to the way in which this crisis is met.

2. Compliance with medical recommendations is not always synonymous with satisfactory adjustment. The impact of the emotions on the progress of tuberculosis is well established. The acting out of resistance may upset the staff but benefit the patient. Attempts to impose certain standards of behavior on patients increase resentment. Acceptance, on the other hand, of these reactions as normal, and of patients as people with a right to express their opinions lessens their need to fight persons who are helping them fight their disease.

3. Skilled professional staff of the several disciplines should be available to provide their interrelated services throughout the course of diagnosis, treatment, and rehabilitation. The assistance of family members and friends must be mobilized to lend support to the patient and facilitate his acceptance of needed care. Community resources should be accessible, and their staffs should have an adequate understanding of the medical and social implications of the disease and of its significance to the individual patient.

4. Special problems often require the development of new skills. Cultural patterns must be understood. When an Indian is hospitalized hundreds of miles from his hogan, his photograph is sent periodically to relatives to show

Choice of administering either the Mantoux test or the Vollmer patch test is made by the county medical society.

To assure statistical information from each testing program, a key punchcard has been devised for machine tabulation. Use of the punchcard is a prerequisite of certification. The program cost includes punching and tabulating costs. The cards give data on age, race, sex, occupation; whether the Mantoux or patch test was used; and whether the reactions were negative, positive, or converter.

A statistical summary of more than 200 schools which have already been certified, including the number of new cases discovered, is included in the full paper.

Once the number of tuberculin reactors in a community is determined, this comparatively small group lends itself to practical reexamination at frequent intervals. It has been proposed that a registry of tuberculin reactors be established in Jones County. As time goes on, other reactors can be added to the list. Plans can be made to X-ray periodically everyone on the registry. The frequency of reexamination will need to be determined from experience. Such a plan is economically and physically possible.

It is reasonable to assume that in Iowa, where in 1954 the rate for new active cases of tuberculosis was 16 per 100,000 population, eradication of tuberculosis can be accomplished by frequent reexamination of every tuberculin reactor.

—PAUL C. WILLIAMSON, *executive director, Iowa Tuberculosis and Health Association, Des Moines.*

Developing a Tuberculin Testing Program in Iowa

Jones County, Iowa, in 1954 conducted a mass tuberculin testing program as a pilot study to determine the infection rate among the general population. The Epidemiologic Study Committee of the Iowa Tuberculosis and Health Association, which initiated the project, wanted to gather statistical data according to age, race,

sex, marital status, occupation, and information according to geographic areas such as urban and rural. In addition, the committee was interested in studying the cost of mass tuberculin testing and its effectiveness as a case-finding device in comparison with miniature film screening programs.

The decision of the county medical society to use the Vollmer patch test was based on the belief that it would be more acceptable to the public, that it would be more economical, and that the testing could be accomplished with limited personnel. At the same time, despite the limitations of the patch test, it was believed the survey would determine the infection rate trend in the community, and, in all likelihood, the patch test would not miss a case of tuberculosis in those tested.

A total of 12,392 persons were tested, or 63.8 percent of the 19,401 residents listed in the 1950 census. Of the population above 5 years of age, 69.1 percent were tested. There were 1,266 tuberculin reactors, amounting to 10.2 percent of those tested.

For both sexes, the highest percentage of reactors occurred in the age group 60-64 years. In men, the peak of 30.1 percent reactors occurred in the age group 55-59 years. In women, the highest percentage of reactors reached 22.1 in the age group 60-64 years. The mean age for all reactors was 42.1 years. The mean age for male reactors was 41.6 years and for female, 42.8 years.

The county was organized similar to the pattern used in fast-tempo miniature film screening programs. A receipt-book type of preregistration slip with carbon copies made it possible to keep track of everyone tested. The remaining slips revealed the name, address, and telephone number of those to be tested. Mobile X-ray units were used as interpretation centers. Each reactor was X-rayed at the time of the interpretation.

A registration card was devised to provide statistical information by machine tabulation. The cards were punched and tabulated according to age, race, sex, marital status, occupation, school, institution, and geographic area.

Tuberculosis Conference

Cancer etiology rates in Cleveland study

Population	Number of persons	Cancer	
		Number	Per cent
Study group-----	666	20	3.0
Number with followup information ¹ -----	593	20	3.4
Excluding definite and probable calcification-----	412	20	4.8
Excluding men under 45 and all women-----	225	16	7.1
Excluding definite and probable calcification, men under 45, and all women-----	161	16	9.9

¹ Does not include 51 persons known to be alive but for whom there is no other information, and 22 not known to be dead or alive.

no case of malignancy was the nodule smaller than 2.0 cm. The nodule was on the right side of the lung in 68 percent of the cancer cases and 61 percent of all study cases. A larger proportion of the medially located nodules were malignant than those in the lateral portion of the parenchyma.

Five hundred thirty-five of the patients (80.3 percent) never had any illness attributable to the nodule. After 5 years only 18 (2.7 percent) had died of the nodule, and only 23 (3.5 percent) of the living had any symptoms attributable to the nodule—17 had tuberculosis, 2 had cancer, and 4 had diagnoses of possible cyst, pneumonia, benign tumor, and suspected tuberculosis. In 90 (13.5 percent) the health status was not determined. Forty-four whose health status with respect to the nodule was not known died of unrelated causes. Twenty-four were known to be alive, but for 22 there is no information at all.

Age-specific mortality rates for the study population and for Cleveland are substantially the same. Although the total mortality among the study group was substantially higher than for Cleveland, the difference is attributed to the higher average age of the study group.

From these findings, it appears that a high index of suspicion of malignancy is warranted in white men over 45 years of age with nodules

of 2.0 cm. or larger. Individualized determination and utilization of every diagnostic tool are essential with the realization, however, that solitary pulmonary nodules are not as hazardous as previously thought. Unfortunately, it is not possible to prove preoperatively in the vast majority of cases which nodules are malignant and which are not.

Recent Tuberculin Testing Experiences in Iowa

Our purpose is to find tuberculosis, and it stands to reason that we should search for it where it is most likely to be found.

With our long years of experience, it would seem that our approach in the future must give greater attention to those persons who are harboring tubercle bacilli in their bodies by evidence of their reaction to the tuberculin test.

Since 1952, an epidemiological study committee of the Iowa Trudeau Society has been investigating the extent of tuberculosis in Iowa. Among other things, the committee was curious to know the infection rate among the general population.

Investigation revealed that some tuberculin testing has been done in various locations in the State, but the programs varied widely from the standpoint of selectivity and techniques, and little emphasis was placed upon the accumulation of data. Thus, attempts to gather information on tuberculin testing were soon abandoned.

The committee felt that uniformity of procedures in tuberculin testing would have to be established in order to evaluate the amount of tuberculosis infection and agreed upon two approaches: school certification and mass tuberculin testing on a countywide basis.

The Iowa Subcommittee on Tuberculosis of the American School Health Association was appointed in December 1954. The subcommittee established standards to be observed in tuberculin testing of school students and school personnel in Iowa. Schools which meet the established qualifications receive the association's tuberculosis control award.

was 4 times greater than in the same period in 1954. On the other hand, 141 cases occurred in the nontuberculous pulmonary patients. Here, incidence in cases in the last 3 months of 1955 was 8 times greater than in 1954.

One hundred twenty-five cases of persistent infection occurred in the tuberculous group, and 60 cases in the nontuberculous group. In the former, incidence in cases in the last 3 months of 1955 was 26 times greater than in 1954.

To summarize, of the 298 primary cultures for atypical chromogenic acid-fast bacilli recovered from both groups of patients:

- 45 percent were from patients having treated active pulmonary tuberculosis.
- 3 percent were from patients having untreated active tuberculosis.
- 4 percent were from patients having inactive tuberculosis (both treated and untreated).
- 3 percent were from patients having treated nontuberculous pulmonary disease.
- 45 percent were from patients having untreated nontuberculous pulmonary disease.
- 44 percent were known to have had, at one time or another, cultures positive for *M. tuberculosis*.

Alarming increases in incidence of new and persistent chromogenic infections are occurring in tuberculous patients and in patients with nontuberculous pulmonary disease. Since our knowledge of the genesis of these organisms and their pathogenicity for man is incomplete, the prevailing situation should be of great concern.

—MARIE L. KOCH, PH.D., *bacteriologist in charge, Clinical Laboratory, Wood Veterans Administration Hospital, Wood, Wis.*

Correlation With Socioeconomic Conditions in New York City

Since the beginning of the antituberculosis campaign in the United States, health authorities have paid special attention to the specific and nonspecific factors that influence the course of tuberculosis. The present investigation of socioeconomic conditions and known tubercu-

losis prevalence in New York City demonstrates one approach to some of the existing community problems in tuberculosis control. The full paper describes and supports with statistical evidence the association of known tuberculosis prevalence with unsatisfactory housing and inadequate income. It was published July 1956 by the New York Tuberculosis Association under the title "Socio-Economic Conditions and Tuberculosis Prevalence in New York City."

During the 3-year period 1949-51, the tuberculosis prevalence rate for New York City, which includes 5 boroughs, averaged annually 369 per 100,000 population. In Manhattan the rate was 665, or 80 percent higher than the overall average, and in Queens the rate was 32 percent lower, or 252.

At the same time, according to data available from the last decennial Federal census, the median family income during the year 1949 was \$3,526 for the entire city and \$3,073, or \$453 less, in Manhattan, but nearly \$600 more, namely, \$4,121, in Queens. In other words, the highest tuberculosis prevalence rate occurred where income was lowest, and the lowest tuberculosis rate was found where income was highest.

The proportion of dwelling units found to be dilapidated or with inadequate plumbing was reported in 1950. As against an average of 9.6 percent of such units for the city as a whole, 18.5 percent of the dwellings in Manhattan were comparatively unfit. But in Queens, the borough with a lower tuberculosis prevalence rate and a higher income, only 4.7 percent of the units were considered to be dilapidated.

It is worth noting that in Manhattan, with the highest tuberculosis rates, 80 percent of the health areas had an average of 200 or more residents per acre. In Queens, 90 percent of the area had fewer than 100 persons per acre. (Health areas are population units, made up of contiguous census tracts, used for vital statistics purposes in New York City. They average about 25,000 persons.)

True, home conditions are a reflection of economic ability to enjoy them. However, the communicable nature of tuberculosis demands

One section of the full report deals with medical management of suspects following X-ray examination of the reactors. In addition, the follow-through accomplished by the public health nurse is outlined, and a cost analysis is included.

—PAUL C. WILLIAMSON, *executive director, Iowa Tuberculosis and Health Association, Des Moines.*

Treatment of the Nonhospitalized Patient— Advantages and Special Problems

Among tuberculous patients under supervision of the chest clinic of Bellevue Hospital, New York City, 510 have received antituberculosis drugs during the 2½ years since 1953. Nearly half began treatment on the wards of the hospital and were transferred to their homes to complete therapy, which has been continuous and consistent. Other patients were accepted from other institutions or started treatment as clinic patients. Results in this group are less gratifying.

Indications for therapy have been varied. The hospital inpatient service has been utilized when needed for special studies, ancillary services, or for surgical treatment. In this respect, the hospital clinic is well suited to conduct home treatment since hospitalization does not interrupt continuity of supervision. Clinical results have, in general, been consistent with expectations, and it is concluded that adequate treatment can be provided to outpatients when all clinical requirements are met without compromise. Certain groups of patients present special problems which are not easily solved in the clinic. Adolescents and elderly patients fall into this category, as do the occasional uncooperative, recalcitrant patients who are a problem wherever treated.

Best results are obtained when home treatment is begun after careful exploration of personal and social problems, and to this end social services are essential. Provision of diversional activity, rehabilitation services, and education regarding tuberculosis continues to be important but is more difficult for patients scattered

throughout the community than when together under one roof.

Individuals in home contact with patients have been examined and followed. Results are encouraging and suggest that risk is slight when therapy and supervision are adequate.

—FRANCES S. LANSDOWN, M.D., *assistant visiting physician*, JULIA M. JONES, M.D., *visiting physician*, ELEANOR MARTIN, M.D., *clinical assistant visiting physician*, and JEAN F. HUDDLESTON, M.D., *associate visiting physician, all with Bellevue Hospital Chest Service, New York, N.Y.*

Emergence and Distribution of Chromogenic Acid-Fast Bacilli

The full report emphasizes changes in incidence or primary isolations of atypical chromogenic acid-fast bacilli (or new cases of chromogenic infection) and changes in incidence of persistence (or multiple cultures from single individuals) occurring in tuberculous patients and nontuberculous pulmonary patients at the Veterans Administration Center, Wood, Wis.

The period of observation extended from October 1954 through December 1955. For analytical purposes it is divided into 5 successive periods of 3 months each. Two hundred ninety-seven primary cultures were recovered from 6,116 clinical specimens cultured for *Mycobacterium tuberculosis*, an incidence of 4.8 percent.

Results show that, in both groups, changes in incidence of primary isolations undergo seasonal variations which reach their maximum in late fall and early winter, with lesser fluctuations in late spring and early summer. Concomitant cyclic changes also occur in regard to persistence, but only among tuberculosis patients. This phenomenon did not make its appearance in the nontuberculous pulmonary group until the seventh month of the observation period.

One hundred fifty-six cases of chromogenic infection occurred in the tuberculosis patients. Incidence in cases in the last 3 months of 1955

ing to uniform standards. We use an intradermal dose of 0.0002 mg. of a commercial purified protein derivative. The size of the induration is measured and recorded. An induration of 6 mm. or over is considered positive, but all indurations of less than 6 mm. are also recorded.

Each child in the schools is to be tested each year regardless of whether he had a positive or negative reaction the previous year, but special consideration is given to any child who previously experienced a violent reaction. Accurate records provide a detailed analysis and evaluation of the project as it progresses. Data from the records will be tabulated from machine punchcards. An attempt will be made to observe periodically until he leaves school each child who reacts positively. A file of individuals tested will be maintained, and new cases of tuberculosis reported in the future will be checked against this file.

The project nurses, with some assistance from the bureau of public health nursing, make a thorough investigation for the possible source of the infection in the environment of each child having a positive reaction. Tuberculin tests and X-rays of the people with whom he might have had contact are obtained through either the family physician or the Honolulu chest clinic. The name of the private physician is given on the consent slip signed by a parent of each child tested, and the result of the test, if positive, together with an explanatory letter, is sent to that physician.

The tuberculosis register and the records of the bureau of public health nursing and of the chest clinic are checked for all students who show a positive reaction so as to avoid duplication of effort and to obtain some evaluation of the tuberculosis control procedures already in effect.

The main objective of the project, therefore, is to determine how best to use the tuberculin test in the present control program. We wish to determine the case-finding potentials of the immediate examination of the positive reactors and to search for the source of their infection. We are curious about the feasibility of following up these positive reactors and of maintain-

ing a permanent current record of persons tested against which to check new cases as they are reported in the future. Such a study, properly administered over a period of years, should yield valuable information about the epidemiology of the disease and the significance of infection as well as information about the techniques and logistics of tuberculin testing which could be useful in future control plans.

Some of the data from the project are available in the full paper. About 97 percent of the student population in the project area are being tested. Elementary schools (kindergarten through 6th grade) have a prevalence of 3.6 percent positive reactors; intermediate schools (7th through 9th grade), 8.3 percent; and the high school students (10th through 12th grade), 19.4 percent. Although previously undiagnosed cases are being found, the results so far indicate that tuberculin testing as a case-finding procedure is considerably more expensive per case discovered than the present methods of mass X-ray surveys.

—ROBERT H. MARKS, M.D., *chief, bureau of tuberculosis, Territory of Hawaii Department of Health, and HOLLAND HUDSON, executive secretary, Tuberculosis Association of the Territory of Hawaii, both of Honolulu.*

Effect of Chemotherapy on Long-Term Prognosis

During 1930-40 the death rate from primary tuberculosis on the children's tuberculosis service of Bellevue Hospital, New York City, was over 20 percent. Ninety-five percent of the deaths were due to meningitis and miliary tuberculosis, more protracted forms of hematogenous tuberculosis, and local progression of primary tuberculosis with cavitation and bronchogenic spread. With the advent of streptomycin, the death rate fell to 5 percent and more recently to 1 percent. The ultimate prognosis of the survivors can only be determined by long-term followup.

This has been achieved in over 98 percent of cases treated with specific therapy. Reported

that contacts with the disease in or outside the home must be under such conditions as to limit its spread.

Unemployment, and consequent limitation of income, brings with it a weighted chain of reduced income, poorer home conditions, and higher tuberculosis rates. In 1950, in the civilian adult population in New York City, slightly less than 7 percent were unemployed (6.9 percent). In Manhattan, where higher rents are demanded, unemployment was 8.4 percent. Again in Queens, with low tuberculosis rates, unemployment was but half (4.3 percent) that of Manhattan.

In like manner, data on the association of the above-mentioned socioeconomic indexes and tuberculosis rates have been compiled for all 5 boroughs of New York City, for the 30 health center districts in these boroughs and their subdivisions, the 348 health areas.

From these correlations in a great population center, it appears that tuberculosis prevalence is closely associated with housing and income.

The supporting evidence leads to the conclusion that, where urban living is accompanied by inadequate or slum housing, low income, and the deleterious effects of overcrowding and poverty, tuberculosis continues to exist at a higher level of prevalence than where the general physical and social environment is salubrious.

—ANTHONY M. LOWELL, M.P.H., *director, statistical division, New York Tuberculosis and Health Association, New York, N. Y.*

Tuberculin Testing of Honolulu Children

In October 1955 a tuberculin testing project was launched in 26 Honolulu schools. Some 24,000 school children, from kindergarten through high school, will be tested each year for a period of 5 years. The area of the study includes the highest tuberculosis mortality and morbidity rates in the city. Six persons—3 public health nurses plus a practical nurse, a records analyst, and a clerk—are employed full time for the project by the Oahu Tuberculosis and Health Association. Medical direction is

by the chief of the bureau of tuberculosis of the Territory of Hawaii.

In 1930 a tuberculin testing survey in an intermediate school in Honolulu showed a prevalence of positive reactors of over 75 percent. By 1946 the prevalence had declined to 18 percent and by 1955 to 6 percent. These falling rates are part of the background facts which encouraged the long-range study.

Also, the tuberculosis control program in the Territory had received unusually good public support for many years. The relative proportion of beds available for the care of tuberculous patients has always exceeded that of most communities. Intensive case finding through chest X-ray surveys has been in progress since 1942. For a long time approximately one-half of the new admissions to the sanatoriums have been discovered in this way.

In addition, only 6 percent of persons who died of tuberculosis in 1955 were unknown to the health department before their death. The tuberculosis death rate of 55 per 100,000 population a dozen years ago was exceeded by only a few States. Now, the death rate of 6.4 per 100,000 is one of the lowest among the States. Since 1950, the rate has declined 71.1 percent although the number of new cases has declined only 23.4 percent. But the low yield of new cases discovered in the mobile X-ray unit surveys in some areas resulted in a search for more selective surveys and for other supplements to present case-finding efforts.

Some further reasons for studying a different approach to case finding included the occasional discovery of advanced tuberculosis in persons never previously X-rayed, the indifference of some of the population toward X-ray surveys, and the prevailing propaganda that tuberculosis is about finished as a public health problem.

Approximately a year of thoughtful discussion and planning among interested individuals preceded the project. Complete understanding and cooperation were obtained from tuberculosis and health personnel and from representatives of the schools and the medical society.

The technique of administering and interpreting the test has been carefully planned accord-

had had clinical tuberculosis or had died of the disease.

In the period of observation, 1943-53, during which 186,000 person-years were accumulated by the study population, 96 of the girls died, a rate of 50 for 100,000 person-years, when a rate twice as high was expected. Death rates for the group were much lower during the period of training and the early postgraduate years than were corresponding rates for women of the same age in the general population. Rates increased during the period of observation, and, by the end of the period, deaths from all causes equaled or perhaps even exceeded those in the general population.

The findings for two particular causes of death are of particular interest: The number of deaths from tuberculosis was only one-ninth of the number expected, and deaths from violent causes in the later years of the observation period accounted for two-fifths of all deaths. Motor vehicle accidents alone accounted for 14 of the 35 deaths from violent causes. Overdosage of barbiturates, suicides, and carbon monoxide poisonings accounted for 15 more. If the fatal barbiturate and carbon monoxide poisonings were in fact intentional, suicide would then be the most prominent single cause of death in the study population.

Although nurses undoubtedly are more highly exposed to communicable diseases than the general population, only a relatively small number of deaths were caused by such diseases. Instead, the greatest mortality risks of today's young nurses appear to be from causes not directly related to their professional services.

—ANDREW THEODORE, M.A., ANNE G. BERGER, B.A., and CARROLL E. PALMER, M.D., PH.D.,
Tuberculosis Program, Division of Special Health Services, Public Health Service, Washington, D.C.

The Patient's Reaction to Hospital Treatment

This study explored the range and diversity of attitudes toward hospital treatment held by 570 male tuberculosis patients in the Veterans

Administration Hospital, Madison, Wis. How do patients, in this age of chemotherapy and surgical procedures, feel about undergoing pulmonary surgery? What degree of faith do they have in the antibiotics they are receiving? How do they react to prolonged bedrest in the light of these new treatment methods? What are their feelings toward the medical personnel who are entrusted with their care?

Each patient filled out the Madison Sentence Completion Form, an attitude form designed specifically to evaluate the thoughts and feelings of hospitalized tuberculosis patients. In completing the 80 sentences of the form, the patient has an opportunity to express his reactions to bed rest, surgery, and other pertinent aspects of his treatment program. Analysis of responses revealed the following:

There does not appear to be a uniform set of attitudes held by all tuberculous patients. Individual differences in personal reactions and intensity of feelings are striking.

Bed rest tends to place an emotional strain on the majority of patients. Restlessness, depression, nervousness, boredom, and feelings of helplessness are frequent complaints. On the other hand, many patients are able to adjust adequately to long-term bed rest. A minority of bed resters express the feeling that they "never had it so good."

Many patients have marked difficulty in accepting their enforced dependency on the hospital staff. The majority, however, regard their dependency state as necessary for cure and appreciate the help given them.

Most patients indicate confidence in the effectiveness of the antimicrobial drugs and state they have benefited noticeably. Complaints about the disagreeable taste of para-aminosalicylic acid and the discomforting side effects of other drugs are not uncommon.

About half of the patients are willing to undergo pulmonary surgery if it is prescribed. Surgery is generally viewed as a means of speeding up recovery. Strong fears in regard to the operation often attend the acceptance or rejection of surgery. Many patients are either unwilling to reach a decision or indicate that they will turn down surgery.

in the full paper is the present status of survivors in the groups mentioned above who have been followed for more than a year.

—EDITH M. LINCOLN, M.D., *visiting physician, children's medical service, Bellevue Hospital, New York, N. Y.*, and PAMELA A. DAVIES, M.B., *and* GEORGE I. LYTHCOTT, M.D., *both instructors in pediatrics, New York University.*

Candida albicans: A Means of Detecting Tubercle Bacilli on Culture Media

In 1954 I reported that a strain of *Candida albicans* which had been isolated from the sputum of a patient known to have pulmonary moniliasis and which failed to grow on Loewenstein's medium had produced a heavy growth of large creamy colonies on this medium when micro-organisms of *Mycobacterium tuberculosis* were present. In that story attention was directed to the fact that colonies of *C. albicans* develop at the sites on Loewenstein's medium in which there are tubercle bacilli.

This observation has been used to detect the early and as yet macroscopically invisible growth of *M. tuberculosis* on Loewenstein's medium inoculated with portions of specimens suspected to contain the micro-organism.

At the Royal Edward Laurentian Hospital, Montreal, during the past year, more than 1,000 specimens have been examined for *M. tuberculosis* by means of duplicate cultures on Loewenstein's medium. One tube in each set of duplicates was superinoculated with a suspension of *C. albicans* cells on the fifth day following inoculation with the material in which *M. tuberculosis* was being sought.

Examination of the superinoculated duplicates disclosed a heavy growth of *C. albicans* in certain tubes within a few days. Acid-fast bacilli were found among the yeast cells in every instance in which a heavy growth of *C. albicans* developed. The average time between the original inoculation and detection of acid-fast bacilli was 15.6 days. Examination of the control duplicates, on the other hand, only dis-

closed macroscopic evidence of growth of *M. tuberculosis* in 4 to 5 weeks.

The superinoculated duplicates also yielded evidence of *M. tuberculosis* half again as many times as the control duplicates. Up to the present time, most of the cultures of acid-fast bacilli that have been detected by means of, and isolated from, *C. albicans* have produced progressive tuberculosis in guinea pigs. However, 14 strains have been found of atypical chromogenic acid-fast bacilli which upon injection cause guinea pigs to become tuberculin reactors but seemingly do not incite progressive disease.

The fact that the superinoculation method yielded a greater number of positive cultures than the routine method indicates that *C. albicans* contains, or produces, a factor which stimulates the growth of *M. tuberculosis*.

A study of the clinical histories of the patients from whose specimens *M. tuberculosis* was isolated by the superinoculation method and not by the routine method disclosed that some of these persons had a positive sputum only on one or two previous occasions and that many either had been given, or were actually taking streptomycin, isoniazid, or para-aminosalicylic acid.

Preliminary in vitro experiments which have been carried out since the described study indicate that *C. albicans* promotes the growth of very small numbers of tubercle bacilli and that tubercle bacilli which have been exposed to streptomycin or isoniazid either fail to multiply or multiply only at a slow rate on standard culture media.

—EDITH MANKIEWICZ, M.D., *bacteriologist, Royal Edward Laurentian Hospital, Montreal, Canada.*

Mortality Among Former Student Nurses During the Last Decade

Nearly 26,000 former student nurses first placed under observation while in training during 1943-49 participated in a followup study in 1952. The purpose was to determine how many

Health Services for Children of School Age

In school health services, as in the infant and preschool area, the Working Group on Service Programs recognizes wide variations in program content, stages of development, and available facilities in agencies providing school health services.

The Working Group on Service Programs recognizes also that changing concepts and new approaches are vital to the attainment of goals in health programs for school-age children. In view of the fluid state of school health services, it was considered neither desirable nor possible to prescribe specific statistical patterns applicable to all school health programs. Consequently, the proposals of the working group should be regarded as a framework within

which each school health agency may develop a statistical program in accordance with its own needs.

PREREQUISITES

The following conditions must exist if meaningful service statistics are to be developed for a program of health services for school-age children.

1. The objectives and scope of the program must be clearly defined.
2. Education personnel and health program personnel, such as physicians, nurses, nutritionists, social workers, health educators, and statisticians, should have a part in determining the

Service Statistics

The Working Group on Service Programs of the Public Health Conference on Records and Statistics is issuing a series of documents on the collection and analysis of statistics recommended for various health department service programs. As these recommendations are completed and approved by the working group and the conference, they will be published.

An introduction to the series and the basic principles governing service statistics appeared in June 1956, page 519. These were followed in the July issue, page 705, by a statement on service statistics for the health supervision of infants and preschool children.

In developing this statement, the third in the series, the Working Group on Service Programs had the assistance of Dr. Alfred Yankauer, director, maternal and child health services of the New York State Department of Health, as medical consultant.

This report was approved by the conference membership in May 1954. It has been reproduced in mimeographed form as attachment A to document

312 by the National Office of Vital Statistics, Public Health Service, Department of Health, Education, and Welfare, Washington, D. C. Under the title "Guide to the Collection, Analysis, and Interpretation of Service Statistics in Health Services for Children of School Age," it has been endorsed by the Association of State and Territorial Directors of Local Health Services, the Council of State Directors of Public Health Nursing, and the Statistics Section and the Committee on Administrative Practice of the American Public Health Association.

Concurrently, with the development of this statement, the Committee on School Health Service Statistics of the School Health Section of the American Public Health Association was also addressing its attention to fallacies in the way school health statistics are often kept. The report of this committee was published in the *American Journal of Public Health*, May 1956, page 636. Interlocking membership of the two groups was arranged in order to assure basic consistency in the respective statements.

Most patients do not appear upset when hospital personnel and visitors wear masks. Instead, they recognize and appreciate the mask's value as a protective measure. A minority react negatively to the wearing of masks, feeling that it enhances the stigma of the disease.

Patients invariably prefer a physician who is professionally skillful, who explains their medical condition to them in a frank, compre-

hensive, and understandable fashion. On the other hand, most patients prefer nurses for their friendly, personal qualities rather than for their professional competence.

Despite the many frustrations of hospitalization, most patients feel optimistic about the future.

—GEORGE CALDEN, PH.D., *chief psychologist,
Veterans Administration Hospital, Madison, Wis.*

An Important Date

Each month your health department and many hospitals, laboratories, schools, clinics, and homes receive a copy of PUBLIC HEALTH REPORTS, mailed to arrive on the 20th, or even earlier, depending upon geographic location of the subscriber.

Its pages carry timely research reports, analyses of current trends, new methods, concepts, and ideas, and topical reviews for the busy scientist, teacher, or public health worker. Capsule coverage of important public health meetings, like those of the American Public Health Association, help the PHR reader.

You can have your personal copy promptly. Use the subscription blank on the inside back cover. Let the 20th of each month be an important date for you, too.

Scheduled for early publication

Eastern States Health Education Conference
Public Health Begins in the Family
Nerve Gas in Public Water
Progress in Leprosy Research
Recent Surface Disinfection Studies
Group Therapy Behind Locked Doors

STATISTICAL INFORMATION

To determine whether the school health service is meeting its objective, extensive statistical data are needed for planning, administering, and evaluating the operation of the program. The following types of information are suggested for these purposes.

For Planning a Program

Baseline data against which to measure progress in provision of health services are essential. The data suggested below for planning a program should be subdivided, if applicable, according to type of school (public, parochial, or private) which the children attend; or whether they are in hospitals or similar institutions; or whether for some other reasons they are not in school. The data should also be subdivided by agency administering the program and by type of service provided.

1. Population of school-age children by age or grade (or by ungraded classes), sex, and color (where significant).

2. Number of children in entering school population, by grade (or by ungraded classes).

3. Estimates of the future school population.

4. Socioeconomic characteristics of the population by geographic area as indicated by pertinent census data and by intercensal data such as general opinions of school principals, teachers, and nurses; special studies; welfare data; and other health department data.

5. Legal and administrative requirements affecting the school health program.

6. Morbidity and mortality data, by age and cause.

7. Information identifying existing health and medical facilities and personnel and other health resources in the school system and in the community, which would be available through the health department, board of education, other public agencies, voluntary health agencies, and private medical practitioners.

For Administering a Program

The customary daily report of physicians and nurses, which shows the number of examinations given, conditions found, and corrections made, tells little about what has been accomplished and what needs to be done in any classroom. Not all conditions can be corrected, and

not all corrections relate to conditions found upon original examination. The best the health service can do is to get the children under medical supervision. The number of corrections recorded for a current year cannot be directly related to the number of conditions found because the former may be the outcome of an examination in a preceding term or year. A statistical report of corrections, unless related to group examined, fails to reveal the actual service received. For administrative purposes, however, a summary of current information, by geographic area when indicated, is needed.

For the reasons stated, information similar to the following frequently is required, in addition to the baseline data previously enumerated for planning a program.

1. Number of children referred through observation of teacher or nurse.

Practically every school child is observed to some degree for health status by the teacher or the nurse.

2. Number of children examined, with or without the parent being present, by the school physician, by a private physician, or by some other physician; and number examined by the school dentist, by a private dentist, or by some other dentist.

The following information should be organized by the type of agency (board of education, health department, or other) and by the type of physician or dentist providing the service.

Entering children: Number found with and number found without conditions needing attention.

Reexamination of selected grades: Number of children found with and number found without conditions needing attention.

Referral examination by source (specify) of referral: Number of children found with and number found without conditions needing attention.

3. Number of children screened and referred by nonmedical procedures.

Specify type of procedure: Number referred and number not referred for further examination.

4. Distribution of children examined, by health status (with or without health needs), color, sex, and age or grade:

Number of children examined or observed.

Number of children for whom further attention is indicated.

kinds of information needed and in developing plans for its collection. The statistician should function as a member of this professional team in initial planning of the program as well as in program operation and evaluation.

3. The information required should be clearly understood by, and should be acceptable to, medical and dental societies and other participating personnel and agencies.

4. The purpose to be served by the statistical data should be clearly specified. Reports should be prepared only to fulfill specific purposes.

5. Provision should be made in advance, during the initial planning stage, for periodic evaluation of statistical procedures.

6. Statistics developed for health services to school-age children should be correlated with statistics developed for related programs of the health department. One means toward this end is to have a records committee periodically pass on and review basic statistical forms of the several programs.

Other factors involved in effective evaluation which cannot be totaled and tabulated, such as local physicians' cooperation, availability of adequate facilities and qualified personnel, and attitudes and habits in relation to health, must be borne in mind.

BASIC CONCEPT AND OBJECTIVES

It is generally accepted that a program of health services for school-age children should consist of three major segments: health instruction, maintenance of healthful environment, and health services. This report is confined to suggestions for the development of statistics related to health services. School health services may be provided by the health department, by the board of education, or, in some instances, by another agency.

The emphasis in school health programs has changed from merely finding and correcting physical defects to the health appraisal of children as individuals, the solution of their overall general physical and emotional problems, and the education of the child and family in healthful living.

It is agreed that health programs for children of school age should be sufficiently broad

in scope to include not only services for children in public, private, and parochial schools but also services for school-age children who, for health or other reasons, are not in any school. Information should be available on the services provided for each group.

It is recognized that data on the child not registered in school may be difficult to obtain, but, when such information is available, it is desirable to include it in administering a program. Possible sources are records from public health nursing offices, crippled children's services, and special clinics.

Because of the many variations in school health programs, no standard pattern of services prevails. However, it is possible to set forth basic objectives toward which all programs are directed to a greater or lesser degree. These objectives may be stated briefly as:

1. Finding children in need of medical or educational observation, counseling, and treatment by:

Observation by teacher or nurse.

Appraisal by physician and dentist either through school health services or through some other source.

Nonmedical screening (vision, hearing, dental inspection in school, height and weight measure, health inventory) and self-referral.

Absence from school or nonregistration.

2. Followup (and continuation of followup) of child in need of care to the point of definitive diagnosis or to the point of receiving care, and giving care where it is within the scope of the program. Examples are:

Observation by teacher or nurse.

Examination by school physician.

Counseling by nurse, physician, and others that child seek service or treatment.

Examination by specialist or consultant.

Provision of immunization.

Medical or dental treatment.

Provision of special education service.

Obtaining report of service provided.

Implementation of report, if further service is indicated.

3. Minimizing the hazards of school attendance by means of communicable disease control and accident prevention.

4. Provision of emergency service, such as care of injured or sick in school.

5. Health guidance and counseling through contacts with children, parents, teachers, and community agencies.

For Evaluating a Program

The working group believes that analyses of results of medical examinations, case-finding services, and followup data would be more valuable than many unrelated statistics currently being accumulated. In addition, periodic analysis of the school health record of each child is desirable. It is not necessarily recommended that the entire program of school health services should be evaluated routinely. Detailed analyses are generally more useful when handled as a special study.

Medical Examination

Studies of records of medical examinations can provide indexes of health needs. Analyses of physical defects by type and severity of condition can provide data useful both in indicating preventive measures and needs for services. In considering medical examinations as an index of health needs, it should be borne in mind that the diagnostic findings of the school physician's examination cannot always be definitive and that his examinations may not cover that portion of the school population examined by private physicians. Moreover, records and reports of the private physician may not be comparable with those of the school physician.

Case-Finding Services

Information and data of the following type are useful for analyzing case-finding services:

What was the source of finding the case?

What was the type of condition found?

Was the needed service provided? (This is useful information both for evaluating the program and for indicating gaps in community services.)

How many conditions found for the first time in reexamination might have been found earlier (either by a more careful referral program or at the time of a previous examination)?

How much over-referral and under-referral resulted from nonmedical screening or teacher observation?

Followup Data

Information regarding followup activities and the results obtained from followup are probably the most revealing index to accomplishments of the school health program. The

final results of followup, or some record as to whether the condition is in need of followup, should always be clearly stated in the basic record. At the time of a reexamination, current findings should be reviewed to determine what services the child has received as a result of the findings in the previous examination.

Information on the health status of the child, based on his condition at an interval after the initial finding together with an accounting of what has been done in the interim, is valuable for program planning and operation. This type of reappraisal after reasonable followup provides a measure of evaluation of the services provided.

A periodic review of individual records, annually if possible, is a better source of material for evaluating services performed and the results obtained than the compilation of daily reports of physicians' and nurses' activities. Records of children needing further attention should be analyzed more frequently than records of other children.

School Health Record

Inasmuch as the ultimate goal of a health program for school-age children is better service for the child, it is important to have a separate health record for each child. Because successful evaluation of the program is dependent on the extent to which necessary information is available, the school health record should be designed to provide information on the type of service provided and on the findings, and to give specific recommendations for further services based upon casefinding and followup, illness and accident data, and pertinent absentee data.

TABULATION METHODS

The following methods are suggested for tabulating program statistics. They may be used in combination.

Manual methods. Abstracting information by manual sorting and counting individual case summary cards, or tally sheets, is applicable to small health departments, but these methods do not lend themselves easily to correlation of information.

Marginal-punched, hand-sorted cards. This

Number of children with conditions, single or multiple, needing attention.

Number of children not needing any further attention.

Number of children, and percentage of total children examined or observed, in specified diagnostic groups.

5. Distribution of children with and without health needs by method of finding.

Breakdown according to:

Medical examinations (whether new admission, re-examination, that is, periodic additional examination, or whether referral by teacher, nurse, or parent).

Screening.

Teacher observation.

6. Types of conditions most frequently needing attention, such as nutritional, vision, cardiac, skin, ear, and orthopedic conditions, or behavior problems.

These might be listed according to:

Static handicap (such as club foot) which should be noted.

Handicap which needs attention but which is not receiving it.

Handicap which is receiving attention but which should be followed to see that attention is continued.

7. Diagnoses showing statistically significant differences observed in color, age, and sex groups, or for other important variables; for example, economic status and geographic location.

8. Statistics relating to the volume of other services, such as immunizations, dental services, first aid.

These data need not be collected routinely but may be the basis for special study.

9. Statistics of services not rendered; for example, services which are planned but which are not possible to provide, and the reasons why.

10. Statistics of followup services for children found by the several casefinding methods.

These data have to be obtained on a longitudinal basis, that is, over a period of time.

11. Counts of some educational services, such as number of nurse conferences with school staff, teacher-nurse conferences, talks to community groups.

These items do not measure quality, but they do tell what is being done with respect to selected aspects of the program. It is not necessary, however, that complete information of this kind be kept constantly. The desired in-

formation may be obtained through special studies at selected time intervals.

12. Data on a number of special services that may or may not be administered by health or education departments.

These are the services provided for handicapped children of school age and the services provided by cardiac and tuberculosis clinics. Data on such services should be correlated with regular school health statistics.

13. Summary of results of previous findings.

As a supplement to the types of current reporting listed in paragraphs 1-12, a summary of the action taken is also suggested. For a particular group examined in the previous year, a summary record would reveal whether the children who needed attention received it during the 12-month period following the examination. Summarized information of this type gives a more satisfactory picture of the accomplishments of the program and what remains to be done than does a detailed count of conditions found and corrected within a current year.

14. Analyses of absences by type of illness and length of absence.

Absentee records are a potential source of useful data for indicating preventive measures and needs for services and for reflecting acute and chronic conditions. Absentee records would be analyzed only as a special study, especially when the absences are repeated or long-term absences occasioned by illness. It is important to know the reasons for absence, to know how many conditions received attention, what are the needs of children who did not receive care, how much absenteeism could have been prevented, and to what extent absenteeism might have been shortened.

15. Data on the types and results of accidents.

Inasmuch as accidents are the leading cause of death among children of school age, accident statistics, if they are to be complete, should contain information on the nature of the accident, part of body injured, how, when, and where the accident happened (supervised or unsupervised play), treatment given, followup needed, days absent, and whether a physician was required. Accident data are valuable for planning educational programs of accident prevention and correcting the conditions which lead to the occurrence of accidents.

For health workers, students, and others unfamiliar with techniques of industrial hygiene, a definition of terms and an explanation of the procedures in the technology of air sampling are contained in this talk presented to the chemical section of the 43d National Safety Congress and Exposition, Chicago, October 18, 1955.

Some Basic Principles and Problems of Air Sampling in Industry

By CHARLES D. YAFFE, M.S.

INDUSTRIAL HYGIENE is concerned with everything in the working environment including, of course, the air surrounding the worker. That air, in addition to its normal constituents, may contain foreign substances or contaminants in solid or gaseous form. Unless it is prepared specially in the laboratory, air always contains some contaminants, so it is not strictly correct to say that air is "normal" only when it is "pure." One of the objectives of air sampling is to determine how much of a given contaminant is present in the working atmosphere.

Types of Airborne Contaminants

Airborne contaminants may all be classified chemically. They may be further sorted into

two major groups, depending on whether or not they are living matter, such as bacteria, viruses, or molds.

In addition to finding impurities of a chemical nature in air, we also encounter various forms of energy such as light, sound, and radioactivity. These are also parts of the working environment that are of interest to the industrial hygienist. Again, as with airborne substances, these are normally present everywhere, and our interest is primarily with "how much." The measurement of these energy forms, which are sometimes referred to as physical agents, is a broad and complex subject outside the scope of this present discussion, which will be limited to the airborne contaminants referred to as chemical agents.

The methods employed in measuring the amount of a contaminant will depend on the form in which it exists in the air. The forms in which contaminants are found in the air may be classified as dusts, fumes, gases, vapors, and mists.

Dusts and fumes are solid particles which differ in their size and method of production. Dust is produced when solid material is broken up by such operations as crushing, grinding, drilling, and blasting. Fumes, on the other

Mr. Yaffe, chief, Program Services, Occupational Health Field Headquarters, Public Health Service, Cincinnati, is also one of the technical editors of the Encyclopedia of Instrumentation for Industrial Hygiene, published April 1956 by the University of Michigan in cooperation with the Public Health Service.

method permits ready analysis where the volume of service is not large enough to justify mechanical tabulation.

Mechanical tabulation. This method is practical in health departments with a large volume of services.

POINTS FOR EMPHASIS

Advance planning for the collection of data is an important aspect in the accumulation of meaningful statistics. Program directors, nursing personnel, statistics staff, field personnel working with the records, school administrators, and teachers should be included in the planning. Within the program area there should be clear understanding of the definitions and need for uniformity in recording and reporting. Particularly is it important that local medical and dental societies have such understanding.

Final responsibility for decisions regarding terminology and classification would seem to rest with program directors working with the education and nursing personnel, statistics staff, and members of the field staff who use the records.

Statistical approaches to health needs of children of school age are complicated and should be undertaken as a well-defined study. For statistics to be meaningful, an adequate followup system should be provided, and a concise record should be maintained of the service rendered. In analyzing school health data, one area of information at a time should be mapped out for study. As the usefulness of the collected information is determined, specific items can be continued or dropped as indicated.

Compilation of all service statistics on a school-year basis is recommended for comparison with baseline data. Where these statistics are required for fiscal purposes, compilation on a fiscal-year basis should supplement, but not substitute for, school-year data. The working group cautions against more frequent tabulations than are justified by use.

With the trend toward having children examined by the family physician instead of by a

physician employed by the school or health department, the collection of statistics on conditions needing attention becomes even more difficult. Accurate sampling studies within a school health service are believed to be more fruitful than the year-by-year accumulation of meaningless numbers of different categories of conditions. Cooperation with local and State medical societies is important in making the special studies. Special studies done on a sampling basis, when indicated, are recommended as a device to reduce the number and complexity of routine reports wherever possible. Routine reports should concentrate on minimum essentials for reflecting program activities and should avoid over-refinement of data.

The working group believes that the frequency with which specific reports should be compiled must be determined locally, depending on uses to be made of the data. It recommends that unduplicated counts of school-age children served would be most meaningful when tabulated annually, on a school-year basis if possible.

Statistical measurements of service should be interpreted in relation to baseline data, need for services, and program objectives. Only thus can an approach be made to evaluating accomplishments of a program.

Traditionally, age breakdowns have been regarded as providing an essential basis for determination of health needs. The working group believes, however, that insofar as school health services are concerned a grade classification would be more practical administratively inasmuch as records are usually kept by grade and little is lost in the way of age classification. Some general information on range of ages by grades and by various types of schools should be available, however, so as to relate school health service statistics to other available statistics.

In formulating this statement, the working group has emphasized throughout the importance of data analysis as well as data collection. The group believes that, for maximum utilization of service statistics, further expansion of this phase of statistical study should be carried out through the team approach.

been and probably will continue to be difficult to answer for a long time to come.

It is not a simple matter to determine how toxic a substance is, particularly when the avenue of attack is through the lungs. This is true for several reasons. One is that the amount inhaled will vary according to how much physical effort is involved on the job. A man doing heavy work will require much more air than a man in a sedentary job, and he will, therefore, take in more of any contaminants in the air. Another problem, with dusts, is that the amount penetrating into the lungs depends on the size of the particles. Another complicating factor is the sometimes considerable variation in individual susceptibility. Two men may work side by side for many years in a dusty atmosphere. One may eventually die of silicosis while the other never develops any measurable disability attributable to the dust.

The range of variation is extended even further when we include the person who has an allergic response to even minute amounts of a substance. Another important complication

Fritted bubbler.

arises when a contaminant has more than one possible effect. For example, suppose it is found that a great number of people work with a given material without discomfort or evidence of injury provided the concentration of the substance in the workroom air is kept below a certain point. Let us assume, however, that an analysis of the death certificates of people who had worked with the material reveals that the cancer rate among the group is twice as high as for people who did not handle the material. The question then arises, "Did this material cause the increase in the cancer rate?" If, and this is sometimes a big "if," the relationship is clearly proved, the next and more difficult question is, "How much of this material is necessary to cause cancer and how long must the period of exposure be?" Fortunately, most materials do not present such complex problems.

We frequently do have the problem, however, of distinguishing between what is acceptable exposure for short periods of time and what is the maximum amount of the substance that can be safely tolerated 8 hours daily, 5 days a week,

hand, are formed by the condensation of solid substances which had been vaporized by heat, such as would occur in welding or furnace operations of various types.

Dusts are generally larger in size than fumes although there are no definite size limitations for either. Large dust particles usually do not present serious hazards to health because, first, since they tend to settle to the ground quickly, they are less subject to inhalation, and, second, if they are taken in, they are usually trapped in the nose and seldom penetrate into the respiratory system to a point where they may remain long enough to cause injury.

Ordinarily, for health purposes we are interested in dust particles smaller than 10 microns in size. A micron is 1 millionth of a meter or approximately 1/25,000 of an inch. A 10-micron particle is about the smallest that can be seen with the naked eye. Most of the dust that is our concern has been found to be between about one-half micron and 3 microns in size although the electron microscope has shown the frequent presence in the air of many smaller dust particles. The electron microscope has also shown that more of this very fine material is retained in the lungs than was formerly believed.

The size range of dust particles produced by industrial operations will vary, depending on both the process and the material involved. The average or median size of industrial dust as determined with the ordinary optical microscope is usually fairly close to 1 or 2 microns.

Fume particles are generally smaller in average size than the dust particle; the maximum size is usually below one-half micron. Fume particles can join together, however, so that with time the average size may increase after formation.

Gases include those elements and compounds that are found only in gaseous form at ordinary temperatures and pressures. Oxygen, nitrogen, carbon monoxide, carbon dioxide, and chlorine are well-known examples.

Vapors are the gaseous forms of substances that also exist in liquid form at ordinary temperatures and pressures. Common materials of this type are water, gasoline, carbon tetrachloride, benzol, and mercury.

Mists are droplets of liquids, produced either

by atomizing, as in spray painting, or by condensation, as with water that becomes fog or steam. Because mists are particulate in nature, they may sometimes be collected with the same kind of instruments used for dusts or fumes.

My remarks here omit any discussion of the sampling of airborne micro-organisms, such as bacteria, except to mention that they are often of the same size range as dusts and fumes. Though sampling instruments for those particulates often are capable of collecting airborne micro-organisms, some of the instruments kill the organisms and are therefore considered undesirable in biological sampling studies.

Appraisal of Health Hazards

Before discussing actual sampling methods, we might ask, "Why analyze the air?"

Air often is analyzed for purposes other than to determine health hazards. Industry frequently samples the air in certain locations to determine the presence of leaks which could represent a loss of valuable material or of a fire hazard, an explosion hazard, or a nuisance to the neighborhood. Smoke is measured to determine whether an operation is contributing to a community air pollution problem as well as to find out whether fuel is being utilized efficiently. Information obtained when sampling for one purpose can often be of considerable value for other purposes. For example, concentrations of poisonous materials that are low enough to be breathed safely for an 8-hour work period are without exception far below the lower explosive limit. In other words, if the health hazard is controlled, the explosion danger is eliminated too.

The sampling of air for so many purposes means that the associated problems have been approached independently by various groups, each having different aims, backgrounds, and viewpoints. The resulting interchange of ideas has been beneficial to all concerned. Principles developed for one objective have often turned out to be exactly what was needed to achieve other objectives.

Now, let us consider specifically some of the methods and problems connected with the appraisal of health hazards. The first question is, "How much is too much?" This has always

been and probably will continue to be difficult to answer for a long time to come.

It is not a simple matter to determine how toxic a substance is, particularly when the avenue of attack is through the lungs. This is true for several reasons. One is that the amount inhaled will vary according to how much physical effort is involved on the job. A man doing heavy work will require much more air than a man in a sedentary job, and he will, therefore, take in more of any contaminants in the air. Another problem, with dusts, is that the amount penetrating into the lungs depends on the size of the particles. Another complicating factor is the sometimes considerable variation in individual susceptibility. Two men may work side by side for many years in a dusty atmosphere. One may eventually die of silicosis while the other never develops any measurable disability attributable to the dust.

The range of variation is extended even further when we include the person who has an allergic response to even minute amounts of a substance. Another important complication

and, where community air pollution is involved, 24 hours a day for an indefinite period.

Negative and Positive Data

Toxic materials do not all act in the same fashion. Some may be stored in the body until a certain excess is accumulated, whereupon the individual suddenly develops symptoms of toxicity. Other materials may be eliminated without injury occurring unless the initial dose is large enough to cause immediate effects. Still others may cause definite harm directly in proportion to the amount absorbed. Recovery may or may not occur, depending on the nature of the damage inflicted.

Actually, despite the difficulties in working out recommended standards for substances, much useful information has been developed for a number of elements and compounds, and reasonably satisfactory benchmarks have been established for many others. Each year our knowledge becomes more precise. The infor-

Carbon monoxide sampler.

Midget impinger.

mation comes both from laboratory research on animals and from practical experience in the field where the safety factor is put to the test by people at work.

It is here that air sampling provides its maximum usefulness whether the environment is hazardous or not. It is as important to measure what is safe as to measure what is dangerous, for the objective is to provide healthful surroundings, and these must be defined. For this reason, negative data are at least as valuable as positive data.

Since different substances have different toxicities, the amounts that are dangerous will differ. The quantities involved where air sampling is concerned, however, usually have one thing in common: The actual amount collected and available for analysis is extremely small. More precise techniques than those ordinarily needed in analytical procedures, therefore, often have to be employed.

I am reminded at this point of 99.44 percent purity. Let us consider the 56 one-hundredths

1 percent of an airborne impurity such as, carbon monoxide. Concentrations of gaseous contaminants are usually expressed as parts per million. One percent equals 10,000 parts per million; therefore, 0.56 percent is equal to 560 p.p.m. A person breathing air containing that much carbon monoxide would die in less than an hour.

The maximum acceptable concentration for carbon monoxide for an 8-hour exposure is 100 p.p.m., or 1 one-hundredth of 1 percent. Thus, so far as carbon monoxide is concerned, the air must be at least 99.99 percent "pure."

While carbon monoxide is a dangerous adversary, which must be treated with great respect because it is odorless and colorless, there are other far more poisonous gases. The allowable limits for arsine, phosphine, and ozone, for example, are much less than 1 p.p.m.

Size and Type of Sample

The amounts of some solid materials which must be measured as dust or fume are also exceedingly small. As an example, the recommended limit for 8 hours' exposure for cadmium is 0.1 milligram per cubic meter of air. Or, in units easier to visualize, the limit would be approximately 1 ounce in 10 million cubic feet of air. Fortunately, analytical techniques do not call for an ounce of material. Sampling equipment capable of handling 10 million cubic feet of air in a reasonable time interval might lack portability, to say the least. As a matter of fact, laboratory methods are so sensitive that we can readily determine whether the limit for cadmium is exceeded by analyzing the amount removed from 20 to 30 cubic feet of air. The same is true for most other particulates.

The amount of a contaminant in the workroom air may vary considerably during the course of operations. Consequently, we are often interested in extremes of exposure as well as in the average exposure since very high concentrations for a short time may sometimes cause trouble even though the average for the day is not excessive. Therefore, we need to collect two different classes of samples: one for long periods to measure the average exposure, the other for short periods to give information about the fluctuations in concentration.

The time required to obtain an accurate evaluation of the average exposure will, of course, depend on the length of the operating cycle, on variations in production rates, and so forth. The average concentration of vapor around a cleaning vat where parts, all of one type, are carried on a conveyor at a uniform rate might be determined satisfactorily from an hour or so of sampling whereas an operation of an intermittent nature and of varying workload might require a number of samples collected over a period of days or even weeks, and, in some cases, the collection of single samples for hours or even days.

The time interval employed in the individual samples collected for measuring fluctuations in concentration depends on needs and also on the instruments employed. Some devices used for such purposes collect what are variously called "instantaneous," "snap," or "grab" samples. With these the volume of air sampled is small, ranging usually from a few cubic centimeters to the amount held by a small bottle or flask. Ordinarily, a few seconds or less is sufficient time to collect grab samples. Where large volumes of air must be sampled to get enough material to analyze, equipment designed for long-period sampling may be employed for the shortest time interval practical in the circumstances.

Ideally, a sampling technique should give an immediate answer. A number of instruments and methods which do give desired information instantaneously or within a few minutes have been developed, and the prospects are bright for more equipment of this type. At present, however, measurement of most airborne contaminants requires the collection of samples which must be returned to the laboratory where hours or even days of processing are required to yield the answers.

Types of Instruments

I will not attempt to describe in detail the many types of instruments used in air sampling. Generally, however, they have a source of suction to draw the air through some type of collecting or analyzing device and a means for measuring the volume of air sampled.

If a sample is to be collected continuously over a fairly long period to evaluate average con-

Gas sampling tube.

ditions, or if we wish to sample a relatively large volume of air, we would probably use a motor-driven pump. In atmospheres where the possibility of explosion must be considered, we would probably avoid using electrical equipment and use compressed air or hand-operated pumps instead. The sampling rates employed seldom exceed 2 or 3 cubic feet of air a minute and often are less than a tenth of such rates. Rotameters, pressure gauges, orifice meters, or other appropriate metering devices, may be used to measure the air flow.

The collecting mechanisms employed are numerous because of the variety of contaminants. Particulate material, such as dust, might be collected on one of the many filtering materials in common use or might be picked up by an electrostatic or thermal precipitating device. Another common technique employs impingement. The choice of collector would depend also on whether the dust is to be weighed, counted, measured for size, or subjected to chemical analysis.

Gaseous matter might be absorbed by bub-

bling it through a suitable collecting liquid or by adsorbing it on such material as activated charcoal or silica gel.

Instantaneous or grab-type samples of gases might be collected in bottles or flasks which are first evacuated in the laboratory and then opened at the sampling point. Another technique is to displace the air in a double-inlet type of bottle, usually with a hand-operated pump or rubber aspirating bulb. A simple procedure is to fill the bottle with water; as the water drains out, it is replaced by the air to be sampled.

Sampling devices of various types are pictured in the accompanying photographs. They all have two features in common: small size and simplicity of operation.

As stated before, the preferred instrument is one which gives an on-the-spot answer. Among interesting instruments of this type are simple devices in which air is drawn by means of rubber aspirating bulbs through tubes of chemicals; the chemicals develop immediate color changes proportional to the amount of specific contaminants present. Tubes containing chemi-

Hand-operated pump for filter sampler.

cals are available for measuring carbon monoxide, hydrogen sulfide, hydrogen cyanide, and possibly other gases. Oxides of nitrogen may be measured in the field by collection in large hypodermic syringes and comparing with standards the color developed when suitable chemical reagents are added.

Other more complex devices for obtaining answers in the field utilize some physical characteristics of the contaminant in question. One group of instruments utilizes the principles of combustion. For example, vapors that are combustible may be burned on a heated platinum wire in a balanced electrical circuit. The vapors, in burning, raise the temperature of the wire, increasing its resistance, and the change is measured with a galvanometer. Since such instruments are not specific, it is necessary to calibrate the instrument for the particular contaminant.

Certain substances such as the vapors of mercury and of some chlorinated hydrocarbons will prevent the transmission of ultraviolet

light. This property is utilized in some instruments by measuring the amount of ultraviolet absorption. The measurement is indicated on a dial.

Some instruments indicate the number of dust particles in the air. These devices are usually based on a measurement of the amount of light scattered by the dust. Even though they have certain defects, they are useful in determinations of dust of uniform particle size.

Recording devices are being employed with increasing frequency to provide a permanent record of the air conditions measured continuously at a specific location. When attached to suitable instruments, recorders show the fluctuations in concentration which take place and, when compared with concurrent work records, often indicate where control measures or changes in operating methods are advisable. Recorders operate on various principles, for example, changes in electrical conductivity produced by absorption of such gases as sulfur dioxide.

Maximum and Specific Limits

Before concluding, I should like to return to the subject of limits since air sampling to determine health hazards usually requires a decision by authorities that a hazard is or is not present, and, should it be present, they must also decide how serious it may be.

For many years there have been figures known as M.A.C. values with M.A.C. standing for "maximum allowable concentration." The expression has often been a center of controversy because of differing viewpoints concerning interpretation of the values. In jurisdictions where lists of M.A.C. values are part of legal regulations, some administrators have operated on the basis that any sample showing an M.A.C. to be exceeded is a violation. Similarly, I suppose, so long as the M.A.C. is not exceeded, the interpretation would be that no problem exists.

Actually, of course, the question is not so simple. As I stated earlier, although we now have fairly satisfactory toxicological information about a number of substances, the limits in common use do not necessarily represent similar degrees of hazard. Some limits are established to prevent serious injury or possible death. Others are to prevent concentrations that would be irritating to breathe, though not necessarily dangerous. Still others are to prevent levels of odor that are disagreeable. The degree to which people can tolerate or to which they are at all disturbed by such conditions varies greatly, and it is not possible to determine exactly how much of their disturbance is psychological rather than physiological, nor is it correct to dismiss the psychological condition or effect as unimportant.

Most people experienced in industrial hygiene are aware that M.A.C. values for different substances have different origins and represent different degrees of hazard. Because of this, there has been a search for many years for a better expression than "maximum allowable concentration." "Threshold limit value" is one such term. It implies something possibly less legalistic since more than one type of threshold might be indicated whereas "allowable" presents an inflexible aspect. "Hygienic standards" is another proposed term. None of the proposed expressions has won complete accept-

ance, and, consequently, "M.A.C." is still heard wherever industrial hygienists gather, possibly because of our fondness for initials. A recent movement has considerable backing to use the same initials but to substitute "acceptable" for "allowable."

"Maximum acceptable concentration" would seem to have a good chance for widespread use because it indicates a standard in which the degree of hazard has been given some considera-

Encyclopedia of Industrial Hygiene Instruments

The University of Michigan Institute of Industrial Health and School of Public Health and the Public Health Service Occupational Health Program, Cincinnati, cooperated in the preparation of the Encyclopedia of Instrumentation for Industrial Hygiene. Technical editors are Charles D. Yaffe, Dohrman H. Byers, and Andrew D. Hosey of the Public Health Service.

The 1,243-page volume contains comprehensive information on the approximately 1,000 air-sampling instruments exhibited at the Symposium on Instrumentation for Industrial Hygiene, held at the university, May 24-27, 1954. It also contains 28 technical papers presented at the symposium.

Described are instruments for measuring air velocity and metering air, laboratory-type instruments of specific application to industrial hygiene, instruments specifically designed for atmospheric pollution evaluation and meteorological measurements, instruments for sampling and analyzing air for contaminants in industrial environments, and instruments for measuring sound and vibration, for measuring ionizing radiation, and for measuring ultraviolet, visible, and infrared energy.

Included for each instrument are a physical description, data on performance, and information on uses, operating principle, source, and price. In addition, there are photographs, wiring and schematic diagrams, and operating, calibrating, and maintenance instructions.

The encyclopedia was published by the university in April 1956 and may be ordered from the Publications Distribution Service, University of Michigan, Ann Arbor, Mich.

tion. If so, it might be well to point out that future use of M.A.C. will need to be accompanied with a definition of the intended meaning.

In conclusion I refer those interested to the following discussion of this point taken from "A Guide to Uniform Industrial Hygiene Codes or Regulations," which was issued a few years ago by the American Conference of Governmental Industrial Hygienists.

"Maximum concentrations shall not be used as the sole criterion for establishing evidence of hazard to health or well-being, but the evaluation of a possible hazard shall also be subject to other pertinent factors such as the nature of the contaminant and the frequency and duration of the exposure or clinical evidence of harmful effects.

"Thousands of elements, compounds, and mixtures are employed or encountered in places of employment, and the number of new ones being utilized is constantly increasing. Some of these have been found to injure health if present in the working atmosphere in excessive concentrations. Others, while not producing demonstrable injury, have been found to cause irritation, coughing, sneezing, objectionable breath, or other undesirable results.

"Through actual experience in industry, a great deal has been learned about the effects of some substances. This information has been supplemented by considerable laboratory research. The body of

knowledge regarding toxicity of substances is fairly large and is steadily increasing in size. Much more remains to be learned, however, not only about the newer materials but also about some which have been studied for many years. Honest differences of opinion as to the safe concentrations of some of the more common toxic materials exist among authorities in the field of industrial toxicology. Greater differences of opinion are naturally encountered with respect to the limits to recommend for substances on which there is more limited experience.

"Despite the gaps in our present state of knowledge, specific figures must of necessity be provided at least as a guide toward the definition of what constitutes a safe working atmosphere. Specific figures are desirable not only for the use of the authority in determining essential compliance with codal provisions but also are helpful to industry as benchmarks upon which it can base a design of control equipment which it plans to install. There are some who feel that specific figures should not be included unless there is a great deal of conclusive evidence to justify the figure established. However, if no figure is given for a substance because of the absence of positive proof, when question arises as to the presence of a suspected hazard, the authority must render a decision regardless of whether or not a specific value is contained in the code. Consequently, it is felt advantageous to make the list in the code as inclusive as is possible."

PHS Announcement

Dr. Theodore J. Bauer, formerly chief of the Public Health Service Communicable Disease Center in Atlanta, has been named deputy chief of the Bureau of States Services. He succeeds Dr. Leroy E. Burney, recently appointed Surgeon General of the Service.

With the Public Health Service since 1934, Dr. Bauer has served as venereal disease control officer for the Chicago Board of Health during 1942-48, and as chief of the Venereal Disease Division during 1948-53, when he was appointed to the Communicable Disease Center post.

He is a graduate of the University of Iowa liberal arts and medical schools.

Hospital and Medical Facilities Survey And Construction Program

By JOHN W. CRONIN, M.D.

THE Hospital Survey and Construction (Hill-Burton) Program was instituted in August 1946. Its purpose is to make available adequate hospital, clinic, and similar services to all the people through a program of grants to States for survey and planning; and grants on a matching basis to assist in the construction of public and voluntary nonprofit hospitals, public health centers, and related facilities.

The facility must fill a community need and may be new construction or the remodeling or enlarging of existing facilities. The project sponsor must initiate the project and is responsible for its operation. The Federal Government provides financial assistance, sets minimum standards of construction, and, by law, is restricted from the selection of personnel in the operations or in the administration of the completed facility. All projects must be nonprofit or public in type which render a community service, and, in general, do not discriminate on basis of race, creed, or color.

The Medical Facilities Survey and Construction Amendments of 1954 authorized categorical funds for hospitals for the chronically ill and impaired; nursing homes; diagnostic centers or diagnostic and treatment centers; and, rehabilitation facilities.

Federal funds were appropriated to match State funds to survey the need for hospitals and

medical facilities prior to the utilization of the construction funds within the respective States.

As of May 1, 1956, the total estimated cost of all facilities approved amounted to \$2,284 million. The Federal contribution represents \$740 million and is matched by sponsors' funds amounting to \$1,544 million.

There have been 2,905 projects approved. Of these, 2,035 providing 94,566 beds have been completed and are in operation; 553 projects adding 24,915 beds are under construction; and 317 projects adding 11,580 beds are in the pre-construction stage. A grand total of 131,061 hospital beds, 619 public health centers and many adjunct facilities are provided.

The majority of all approved applications are for general hospitals—73 percent and 94,928 beds. Three percent are for mental hospitals—13,047 beds. Two percent are for tuberculosis hospitals—8,478 beds. Two percent are for chronic disease facilities—7,484 beds. Nineteen percent are for public health centers and one percent for other related health facilities.

Twenty percent of the total funds went to teaching institutions, including 37 university medical school hospital projects. Of the 1,057 new hospitals about 55 percent are located in towns under 5,000 population while only 11 percent are in cities of 50,000 or more people. The civil defense implications are obvious. Five hundred and thirty-five new general hospitals are located in areas which had no hospitals prior to the beginning of the program.

The total annual authorization of this program is \$210 million.

The estimated bed deficit in the United States and Territories as reflected by the official State Plans is 850,000 beds. Progress in alleviating this shortage is slow because of annual population increase and the physical and functional obsolescence of the Nation's existing hospital resources.

In 1955, \$1,200,000 of Federal funds were appropriated for research in hospital services, facilities, and resources by the Public Health Service and through grants for research and demonstration purposes. All of these funds have been awarded to qualified applicants. A total of 27 grants have been made.

Dr. Cronin is chief of the Division of Hospital and Medical Facilities, Public Health Service. This is a summary report based on a paper presented at the meeting of the section on preventive and industrial medicine and public health, American Medical Association, on June 14, 1956, at Chicago, Ill.

Food Poisoning

caused by the **GREAT BARRACUDA**

By SIDNEY PAETRO, M.P.H.

DURING the spring and summer of 1954, four incidents of illness following the consumption of fish were reported to the Broward County Health Department in Fort Lauderdale, Fla. The clinical manifestations of the illness and the results of laboratory and epidemiological investigations indicated that it was fish flesh poisoning, or ichthyosarcotoxism, resulting from ingestion of the great barracuda, *Sphyrna tiburo*.

May 13. The first incident was reported on May 13 by a local physician. Five persons had eaten dinner at approximately 6 p. m. the day

before at a rooming house in Fort Lauderdale. The meal consisted of barracuda, succotash, eggplant, cole slaw, okra, mashed potatoes, banana pudding, hot rolls, coffee, and iced tea. All five persons became ill within 1 to 2 hours after they had eaten. Symptoms and complaints were nausea, diarrhea, metallic taste, and the unusual reactions of cold objects feeling hot and hot objects feeling cold, numbness of the arms and legs, and itchiness. Three pet cats fed only barracuda died within 24 hours.

The barracuda, estimated to weigh 6½ pounds, was caught in the Atlantic Ocean about 1½ miles off the coast of Fort Lauderdale near the 2-mile reef about 4 p. m. on May 11. It was placed in deep freeze soon after it was caught and kept there until the following evening, when it was prepared and then fried in a commercial shortening. One of the victims commented, "The fish was the prettiest, whitest, best tasting fish I ever ate."

Mr. Paetro is sanitarian for the South Broward District, Broward County Health Department, Fort Lauderdale, Fla. Investigation of the fish poisoning incidents was conducted by Richard L. Almeida, chief sanitarian of the department, and the author.

Three of the victims were hospitalized immediately. One was ill for 2 weeks, two for about a month, another for 6 weeks, the fifth remained in bed for 5 weeks and had after-effects of the illness when interviewed almost 4 months later.

Specimens of both the raw and the cooked fish were sent to the laboratory of the Florida State Board of Health on May 13. The laboratory reported that "no organisms commonly associated with food poisoning were isolated."

June 27. Of 10 persons who ate barracuda for dinner at a restaurant in the city of Pompano, 7 became ill in varying degrees. The victim interviewed stated that the onset of illness occurred approximately 4 hours after she had eaten and that she was hospitalized for 3 days. Symptoms included gastrointestinal disturbances similar to those reported in the first incident, temporary loss of speech, and partial loss of touch in the extremities.

In addition to barracuda, the meal consisted of cole slaw, green peas, french fried potatoes, pickled watermelon rinds, bread, butter, and beer. Three barracuda were eaten, all 3 weighing an estimated 15 pounds. They had been caught about 2 miles off Hillsborough Inlet, north of Pompano Beach. The fish were cleaned, brought to the restaurant, broiled, and served the same day caught. No specimens were available for laboratory analysis.

July 9. Between 6 and 7 p. m. a family of eight members ate a meal consisting of barracuda, cornmeal cakes, fried onions, corn on the cob, tossed green salad, cherry pie, and the usual drinks. All 8 became ill, and 5 were hospitalized. The illness occurred from 1 to 5 hours after the meal. A small amount of the fish was given to a neighbor, and a similar quantity was fed a pet dog during the meal. Both the neighbor and the dog became ill. The symptoms in all persons were similar to those previously reported.

The barracuda was caught off the Fort Lauderdale coast near the third buoy at approximately 7:30 a. m. There was no refrigeration aboard the vessel, but soon after the boat docked at 9:30 a. m., the fish was placed on ice. It was prepared and deep fried in fresh commercial shortening the same evening. Comments concerning the fish included, "Nothing unusual"

and "It looked beautiful and tasted delicious." A specimen of the fish which had been kept in deep freeze was sent to Dr. Bruce W. Halstead at the School of Tropical and Preventive Medicine, College of Medical Evangelists, Loma Linda, Calif. Dr. Halstead reported that tests on mice with this sample were "mildly symptomatic."

August 24. At approximately 6 p. m., a man, his wife, and their 4-year-old daughter consumed a meal of barracuda, tartar sauce, asparagus (frozen), salad, cookies, ice cream, and iced tea. The parents became ill in approximately 7 hours; the child, within 10 hours. They reported symptoms similar to those already described plus general weakness and a spicy taste to unspiced foods. The illness lasted 5 to 6 days.

The barracuda was caught, 7 weeks earlier, near the 3-mile reef off the Pompano and Boca Raton coast. It was estimated to weigh 15 pounds. On the day it was caught, a section had been given to a neighbor and the remainder placed in deep freeze. Discussing the illness with the neighbor, we learned that the neighbor and his wife had eaten the fish the day it was given to them and that they had both become ill. They were ill for 3 days.

One specimen of the frozen fish was submitted to the Florida State Board of Health laboratory, and another specimen was sent to Dr. Halstead. The State laboratory reported: "Organisms isolated culturally characteristic of the coliform group." Dr. Halstead reported that tests on mice with this sample "produced very severe symptoms in 1 mouse and 1 mouse died 27 hours after injection, which, according to our routine classification, would indicate that the barracuda sample was moderately toxic."

Health Department Action

It was not possible to obtain a list of foods each individual ate at each of the meals in question. However, a study of the lists of all foods prepared and served at each meal revealed that only one food, barracuda, was common to all.

The health department gave two news releases to the local newspapers during these

months. The first, on July 21, reported the occurrences of food poisoning recorded to that date and requested that the health department be notified should illness follow consumption of fish, particularly barracuda. The second, dated September 1, described the latest incident and urged that all instances of food poisoning be reported and that samples of suspected foods be preserved on ice for laboratory analysis. No reports were received after that of the August 24 episode.

During the course of the investigation, we gathered and studied numerous publications, research papers, and opinions in an effort to determine the cause of an illness the characteristics of which had never before been reported in this area. Presented below is some of the more pertinent information compiled from these sources.

Characteristics of Fish Poisoning

Ichthyosarcotoxism is the technical term for intoxication resulting from the ingestion of the flesh of poisonous fish.

One of the first symptoms to develop is a tingling about the lips and tongue. The tingling soon spreads to the hands and feet and gradually develops into numbness. These symptoms may appear at any time within a period of 30 hours after ingestion of the fish. Gastrointestinal symptoms are said to be reported by about 75 percent of the victims (1). Some persons state that their hands and feet are without feeling, whereas others report that their hands and feet hurt when placed in water. Persons with very severe cases generally suffer impairment of movement and sometimes they are unable to walk or stand (2).

One of the most outstanding symptoms is the generalized sensory disturbance in which temperature sensations are reversed; that is, hot objects seem cold to the touch, and cold objects seem hot. This particular disturbance has been reported from many widely scattered areas of the world for more than 175 years.

Recovery from severe attacks of fish poisoning is usually very gradual. Symptoms of weakness sometimes persist for months after specific symptoms have disappeared. An at-

tack does not impart immunity, and there is no known specific antidote or antitoxin (1).

Clinical reports indicate that the ichthyosarcotoxins from many fish species are powerful neurotoxins. The symptoms are similar to those produced by such compounds as aconitine, muscarine, and curare (3).

There are four major types of ichthyosarcotoxism: ciguatera; Tetraodon, or puffer, poisoning; scombroid poisoning; and *Gymnothorax* poisoning. All of these have many characteristics in common, but they differ as to the predominance of certain types of symptoms. Ciguatera is the type thought to have caused the incidents reported to the Broward County Health Department.

Ciguatera, or Caribbean type fish poisoning, has been known for a number of centuries in the countries bordering the subtropical and tropical waters of the Caribbean Sea, the Atlantic Ocean, and the Pacific Ocean. Although numerous species of fish produce this type of poisoning, one of the common causative species is the *Sphyræna barracuda*.

Ciguatera is considered the least virulent form of fish poisoning. The mortality rate has been estimated to be 2 or 3 percent. Complete recovery from the weakness and myalgia can be a matter of weeks or months (3). Records indicate that not all persons who eat poisonous fish become ill, but one attack of ciguatera does not impart immunity to subsequent attacks.

Besides the usual symptoms of fish poisoning, ciguatera has these characteristics:

1. The onset occurs from 1 to 10 hours after ingestion of the fish.
2. There is a distinct metallic taste in the mouth.
3. There is a tingling sensation and itchiness which may last for days (4).
4. Malaise, chills, fever, prostration, profuse sweating, generalized motor incoordination, muscular weakness, and joint aches are common (3).
5. Cramps may occur in the extremities (4).

Theories Regarding the Cause

Many theories regarding the cause of fish poisoning have evolved over the centuries. Following are some of these theories and the opin-

ions of scientists who have done research in this field.

Food-Chain Theory

According to the food-chain theory of fish poisoning, the flesh of fish is made toxic by the consumption of poisonous plants or animals, such as manchineel berries, certain algae, dinoflagellates and other marine invertebrates, jellyfish, corals, swarming palolo worms, mollusks, and crabs.

Halstead and Bunker state that if this theory is correct, the distribution of the toxin within the fish is probably governed by three principal factors: venous draining of the intestine, detoxication, and metabolic processes of the fish (5). Therefore, a high concentration of the "toxin" should be found in the liver and intestine and a low concentration in the somatic muscle if the fish is captured soon after feeding, and the reverse situation if the fish is caught at a later time.

Hiyama tested organ and muscle tissue of poisonous fish in feeding experiments (2). He did not find that the poison was limited to any particular organ, but he did find that muscle tissue produced the most obvious indication of poisoning. On examination of the stomach contents of poisonous fish, he found neither seaweed nor fragments of echinoderms, but unidentifiable digested remains of small fish. Examination of fish collected in areas inhabited by poisonous crabs showed that most of the fish had been feeding on small siganids; no crab fragments were found. In his opinion, there was no connection between feeding habits and toxicity of the fish.

Poisonous fish have been found at all depths of the ocean; therefore, nothing valid can be deduced from their living habits.

Copper-Contaminated Waters

The theory that fish may become poisonous from underwater deposits of copper, copper-lined bottoms of sunken vessels, or war materials containing copper has received some attention. The copper compounds, according to this theory, are absorbed by the fish and become a part of its body composition, making the fish toxic.

Arcisz considered this theory improbable

since all fish caught near copper banks are not toxic, and, conversely, toxic fish are found where there are no known copper banks (4). The same logic can be applied to sunken vessels or war materials found on the ocean bottom.

Size, Sex, and Development

Many investigators consider the size of the fish an important factor in fish poisoning. They regard large fish as generally more toxic than small ones of the same species. A few authorities believe that small fish are never toxic (4). However, little dependable information is available in this regard.

Hiyama was unable to detect any variation in toxicity with sex of the fish, but he observed a variation in toxicity with age in a number of different species (2). Phillips and Brady believe that sexual maturity is not necessarily a factor in toxicity (6).

Bacterial Contamination

Another theory holds that the toxin is produced as a result of bacterial contamination. The contamination may be on or in the fish before it is caught, or it may be introduced during handling or processing after it is caught.

In studying ichthyosarcotoxism, Halstead and Lively found that the freshness of fish had no relation to virulence of the toxin (3). Cohen and his colleagues (7) and Yasukawa (8) do not believe that the toxic agent is of bacterial origin.

Endogenous Theory

Yasukawa found that the location of the poison varied with different species of fish (8). It is found chiefly in the gonads, particularly in the ovaries, and sometimes in the liver. In his opinion the toxin is not produced until the fish reaches maturity and is most virulent in its action during the spawning season.

Tani found that the toxicity of the puffer was highest during the spawning season of the year (9). The toxicity reached a peak a short time before the spawning season, continued at the same level for a few weeks after spawning, and then gradually declined.

It is known that the reproductive organs and roe of certain fish may be poisonous, but

Phillips and Brady are of the opinion that these cannot contaminate the flesh of the fish directly (6).

An Unexplained Phenomenon

None of these theories would seem to explain why the consumption of barracuda caught off this part of the east coast of Florida in the spring and summer of 1954 resulted in illness. Hundreds of the same species of fish were caught in the same waters during the same period and were eaten without harmful effects. Barracuda from these waters have been eaten in the years before and since; yet no other illnesses of a similar nature are on record.

On the basis of the food-chain theory of fish poisoning, the possibility that the incidents were associated with the phenomenon known as red tide was considered early in the investigation. It was dismissed, however, when we learned that the dinoflagellate responsible for red tide, *Gymnodinium brevis*, has never been observed along the eastern coast of Florida, although it is found periodically along the Gulf Coast.

It is earnestly hoped that research on fish flesh poisoning will be intensified so that outbreaks such as those described here can be prevented. Basic knowledge is needed regarding the factors that cause the flesh of sometimes edible fish to become poisonous, the chemical and pharmacological properties of the toxins, and

means by which poisonous fish can be recognized.

Infectious Hepatitis, Diarrhea, and Typhoid Fever

By GILBERT V. LEVIN, M.S., and HOWARD WEST, M.P.H.

A NUMBER of cases of infectious hepatitis, diarrhea, and typhoid fever occurred during the period August 1954 to April 1955 within a six-block radius in Washington, D. C. Circumstances surrounding the earliest known cases indicated that the diseases might be linked to a common source, a contaminated water supply. Consequently, a three-disease epidemiological study of the approximately 7,000 persons in the area was undertaken by the District of Columbia Department of Public Health.

The incident that first attracted the attention of the investigators to this unusual chain of events took place during the week of January 3, 1955. Seven cases of diarrhea occurred among members of four households occupying a building in the 400 block of Sixth St., SW. The only person in the building who did not have the disease was a 6-month-old infant for whom all water had been boiled. The exist-

ence of yard hydrants and yard water closets in this neighborhood heightened suspicion that the water supply had been contaminated. These obsolete plumbing fixtures cross-connect the water supply with the sewer line so that fresh water standing in the riser pipes can drain into the sewer to prevent freezing in the pipes during the winter. Experience in the District of Columbia and elsewhere (1, 2) has shown that under certain conditions sewage can enter the water supply through the cross connections.

Beginning on January 13, the date the outbreak was reported to the health department, a week-long series of 26 water samples was taken from the area. Two of these samples, one from the building where the outbreak took place and one from an adjacent building, were positive for coliform organisms. Free available chlorine of 0.2 p.p.m. or more was present in all the 26 samples except 3 which came from the buildings producing the coliform-positive samples. The chlorine demand thus demonstrated in this restricted area was further evidence of local contamination of the water supply.

A detailed plumbing survey revealed the presence of numerous yard hydrants and yard water closets in the neighborhood. Many of them were defective. Since the four households had no social contact, were served by different dairies, and had individual kitchen facilities, the circumstantial evidence indicated that the outbreak was waterborne.

During the week of January 25, a case of infectious hepatitis occurred just four doors away from the scene of the diarrhea outbreak. This

Mr. Levin, now civil defense representative for the District of Columbia Department of Public Health, was public health engineer with the department's bureau of public health engineering when the study reported here was conducted. Mr. West has been chief of the biostatistics and health education division of that department since February 1954. He was formerly chief of the Statistical Processing Branch, National Office of Vital Statistics, Public Health Service.

Dr. Ralph Paffenbarger, epidemiologist with the Public Health Service, provided technical guidance in making the study and in preparing the report.

aroused the suspicion that there might be a connection between the two incidents. Infectious hepatitis has been known to be water-borne (3-10).

The infectious hepatitis patient was a school child. Inquiry at the school revealed three other cases, and a check with 13 other schools in Southwest and Southeast Washington, four more cases. A sanitary survey of the two schools involved disclosed nothing to indicate that the disease was being spread by conditions at the schools.

The 8 infectious hepatitis patients and the 7 diarrhea patients all lived within a radius of 6 blocks in Southwest Washington. Also within this area were located three cases of typhoid fever which had occurred in the fall of 1954.

Case-Finding Survey

To determine if an epidemic of one or more of the three diseases was in progress, the health department conducted a case-finding survey March 2-16, 1955. Interest now centered about infectious hepatitis, which is not a reportable disease in the District of Columbia. As the normal incubation period of infectious hepatitis ranges from 15 to 35 days, it was decided to request information back to Thanksgiving Day, November 25, 1954, approximately one maximum incubation period before the date of onset of the earliest known case and a convenient mental landmark.

The area selected for the survey, shown in figure 1, was the smallest considered likely to yield conclusive results. Its 27 city blocks encompassed the locations of the known cases of the three diseases.

Interviews were held with members of 1,579 households out of the 1,955 households in the area, yielding information on 5,519, or 81 percent, of the estimated 6,800 persons living in the area.

Ratios of yard hydrants and yard water closets to the population were determined for possible correlation with attack rates of the three diseases. Information on yellow eyes or skin, white or gray stools, and abdominal tenderness was requested from the interviewees. Positive information regarding the first or second item, together with an associated illness of plausible

duration, was considered a probable case of infectious hepatitis. Only cases diagnosed and verified by physicians were classed as definite cases of infectious hepatitis.

The portion of the city in which the survey

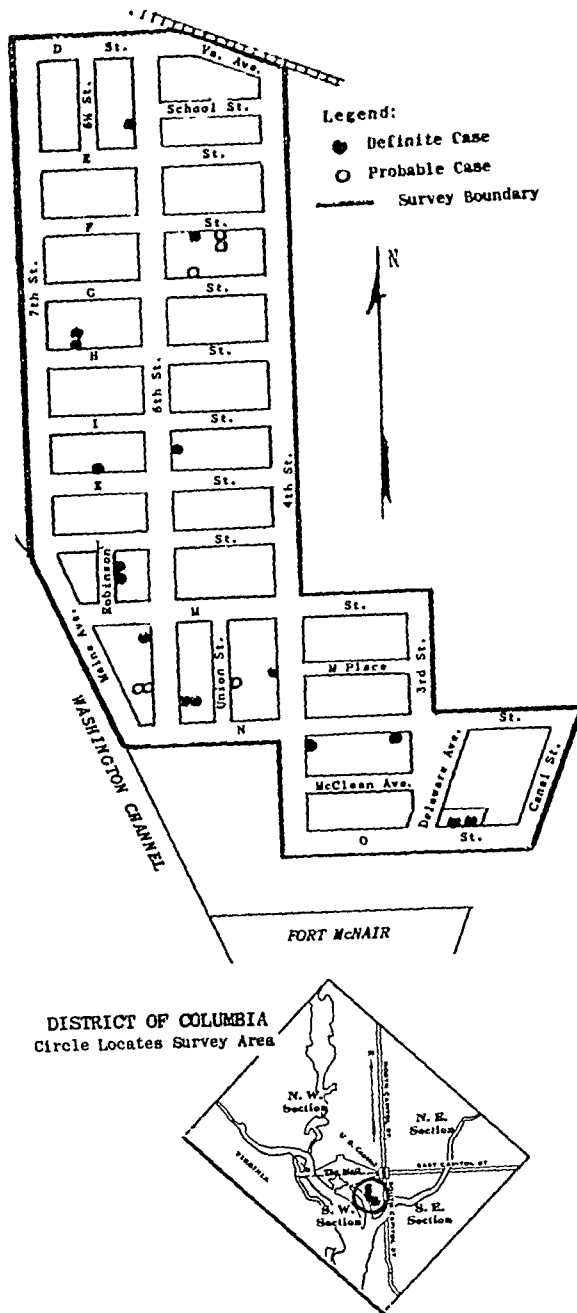

Figure 1. Distribution of infectious hepatitis cases within survey area, Washington, D. C., November 25, 1954-March 10, 1955

area is located is of low socioeconomic status and is characterized as "blighted" to "slum." Most of the buildings are old, two-story, brick, row houses that have been converted into tenements. There are small stores and shops on some of the streets, but no large industrial plants. The area is primarily residential and is inhabited by both the Negro and white races, with Negroes predominating.

The survey area had a population density of approximately 43,200 persons per square mile. Age, race, and sex distributions of the surveyed population are given in table 1. Of the 1,579 households, 27.4 percent had outdoor plumbing fixtures. The households served by outdoor plumbing comprised 1,608 persons, 29.2 percent of the surveyed population.

Infectious Hepatitis

Sixteen definite and six probable cases of infectious hepatitis occurred in the survey area between November 25 and March 10. There was no correlation between incidence and outdoor plumbing. On the contrary, there was strong evidence that the outbreak was propagated by contact. This was demonstrated by a comparison of two ratios: (a) the number of infected persons reporting contact to the total number of infected persons and, (b) the number of noninfected persons reporting contact to the total number of noninfected persons. These ratios expressed as percentages proved to be

Figure 2. Incidence of infectious hepatitis in survey area, Washington, D. C., November 2, 1954–March 10, 1955

23.9 and 0.1, respectively; thus, the rate of contact was 239 times as great for those who had the disease as for those who did not.

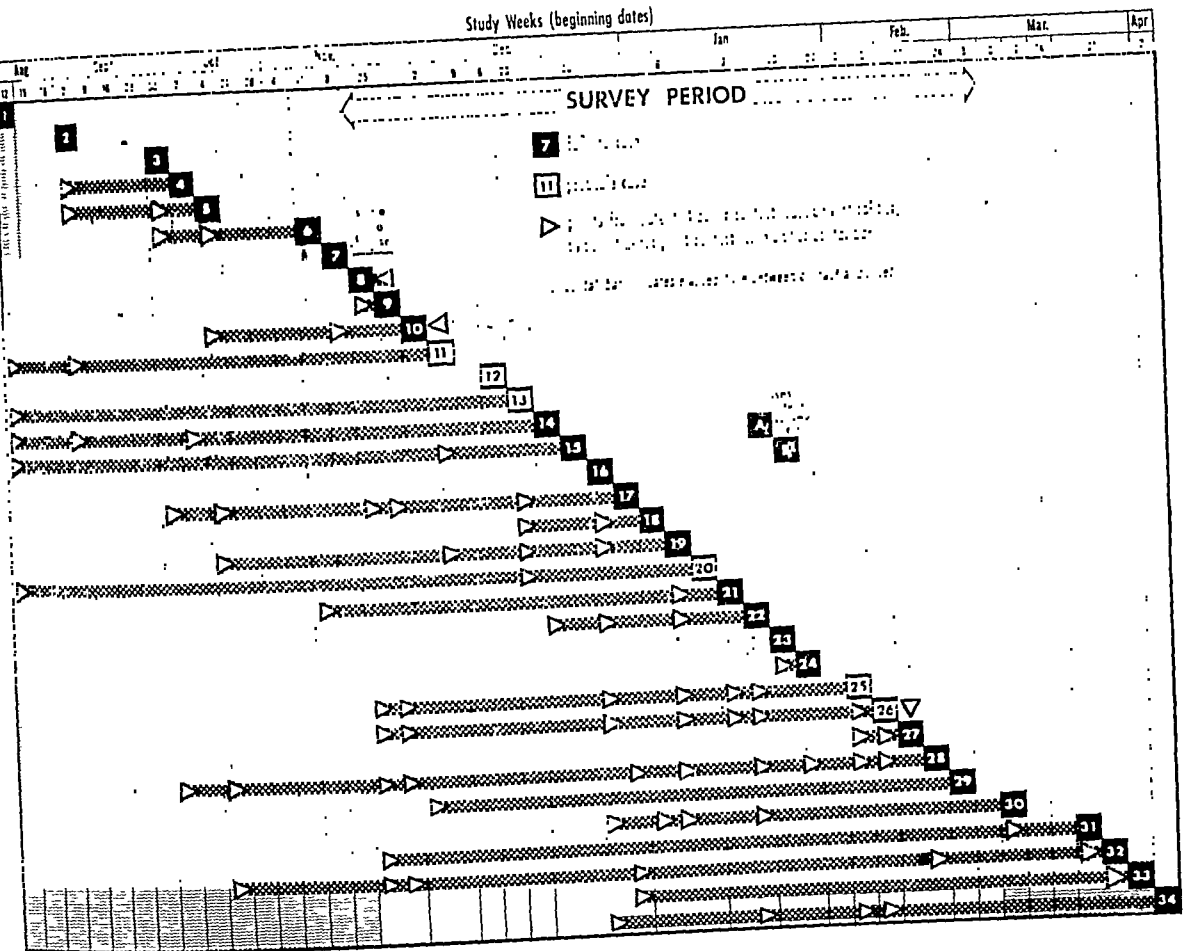

The distribution of the cases by date of onset is given in figure 2. It is typical for contact spread. Distribution of the cases by location is shown in figure 1.

The most striking fact about the outbreak is that it was almost completely confined to white children under 15 years of age. Fourteen of the 16 definite cases and 2 of the 6 probable cases occurred among that group. The number of white children under 15 years of age in the survey area was 620. Thus, the attack rates for that group for the survey period were 2,260 per 100,000 for definite cases and 2,900 for definite plus probable cases.

Figure 3. Chain of "potential contacts" for the 34 cases of infectious hepatitis occurring in the survey area, August 12, 1954–April 14, 1955

The crude attack rate for definite cases was 290 per 100,000 population for the 15-week period; it was 400 for definite plus probable cases. Annual attack rates for reported infectious hepatitis cases in 14 major cities in the United States in 1954 ranged from 5.4 to 141.0 per 100,000 population. Of course, attack rates based on reported cases cannot be compared with rates based on an intensive survey. They are included only to indicate the general level of incidence of the disease.

Four secondary cases occurred during the survey period, 2 definite and 2 probable cases. Eighty-two persons were risks to secondary infections (members of a household in which a primary case occurred) for definite cases, and 105, for definite or probable cases. Thus, the secondary attack rates for the survey period

were 24.4 per 1,000 for definite cases and 38.1 per 1,000 for definite plus probable cases. The ratios of secondary to primary attack rates were 9.6 and 11.7 for definite and definite plus probable cases, respectively. Three of the four secondary cases occurred within 2 weeks of the primary cases. The fourth occurred 12 weeks after its primary case.

In light of the findings of the case-finding survey, the health department made a case-and-contact survey shortly thereafter. An additional 12 definite cases were discovered to have occurred within the bounds of the survey area from August 12 through April 14, giving totals of 28 definite cases and 34 definite plus probable cases for this period. No rates, of course, can be inferred from these numbers since it is unlikely that they include all cases occurring be-

Table 2. Chronology of infectious hepatitis cases by communal place, September 2, 1954–April 6, 1955

¹ Probable case.

fore or after the survey period. The earliest known case associated with the outbreak was that of a woman who worked in a grocery store in the area. While in the store, she had contact with many of the children in the neighborhood; in her case history, she cited four who later became ill.

Analysis of the contact information showed a surprisingly complete chain of "potential contacts" within the limited survey area. A person was considered to be a potential contact if he was named as a contact by a person who had a definite or probable case of infectious hepatitis and if he too was found to have had a definite or probable case. To elicit the maximum contact information from the interviewees, questions were asked regarding persons in the following categories: acquaintances who had had infectious hepatitis since September 6; other patients and their contacts known personally by the interviewee (usually schoolmates); visitors to the patient during his illness; persons associated with the patient in the home environment within 3 days before or 3 days after date of onset. The potential contact chain for the 34 definite and probable cases is shown in figure 3.

For 27 of the 34 cases, the contact information revealed one or more possible sources of infection among members of the group. Only two of the potential donors of the disease lived out-

side the survey area. These facts are a strong indication that the outbreak was confined largely to the survey area. A check with the schools attended by the infectious hepatitis patients, which also draw students from outside the survey area, supported this contention. As shown in figure 1, the survey area has several isolating boundaries: the railroad on the north, the Washington Channel on a portion of the western border, and a military reservation just beyond the southern limit. Several blocks to the east, the buildings had been torn down in a slum clearance project.

When the applicable cases were grouped chronologically by communal places (schools or clubs of which two or more members had the disease), table 2 resulted. These data show that the disease progressed in a fashion typical of contact. Twenty-three of the thirty-four patients were members of six such groups. Intracommunal group contact can be traced by referring to figure 3.

According to available figures, 9.0 to 9.9 percent of all dwelling units in an area similar to, and including, the survey area provide less than 39 square feet of sleeping space per person. For the 30 households in which infectious hepatitis occurred, the percentage was 16.6. For the 6 households in which secondary cases occurred, the figure was 50 percent. (Two secondary cases occurred prior to the period covered by the original survey.) This indicates, as

might be expected, a correlation between incidence of secondary cases and crowding.

All the cases among school children occurred in the white population although the schools are not segregated. Only two definite cases and one probable case, all in persons over 27 years of age, occurred among the large Negro population of the area. These facts arrest attention, but there are two possible explanations. First, classroom contact may not be close enough for spread of the disease, which may take place in more intimate, and still generally segregated, extracurricular activity groups. Second, jaundice is more difficult to recognize and to diagnose in Negroes than in whites. The possibility that the diagnosis and treatment facilities available to the two groups were unequal is not supported by records for the medically indigent of the area.

Diarrhea

Fifty-eight persons had diarrhea during the 15-week survey period, November 25 to March 10, a crude attack rate of 1,050 per 100,000 population. None of these persons knowingly had either infectious hepatitis or typhoid fever during that period. With the exception of the initial outbreak of 7 cases, none of the cases were attributable to outdoor plumbing. On the basis of appropriate population adjustment, diarrhea attacked four times as many whites as Negroes. No explanation for this has been evolved.

The secondary attack rate for diarrhea was 134 per 1,000 exposed persons in the surveyed population. The ratio of the secondary attack rate to the primary attack rate was 15.7, indicating that intrafamilial contact was a potent factor in the spread of this disease.

Typhoid Fever

No cases of typhoid fever occurred during the period covered by the survey. However, the surprisingly large number of 74 persons reported that they had had typhoid fever at some time in the past. Of these, 40.3 percent were served by outdoor plumbing at the time of the survey, as compared with 29.2 percent for the total population. Since many of the 74 had typhoid fever in other homes or even in other

cities, these figures do not indict the plumbing as the source of their disease, but they are of epidemiological significance from the standpoint of typhoid fever carriers.

A check of all available typhoid fever registers in the department of public health yielded records on only 5 of the 74 persons. They were listed as noncarriers. But what about the remaining 69, many of whom live in homes with outdoor plumbing? Furthermore, the finding of these 74 persons, coupled with a knowledge of plumbing conditions in similar areas, implies that there are a large number of persons in the city who have had typhoid fever and who are currently living in dwellings served by outdoor plumbing. That carriers among them pose a real threat is suggested by the fact that during the past 10 years an annual average of 14 cases of typhoid fever has been reported in the District of Columbia.

A 7-year-old girl and 5- and 7-year-old sisters living a block away from her made up the group of three typhoid fever cases reported in the fall of 1954. None had drunk any water other than from the municipal supply within 30 days prior to onset of the disease. The first girl became ill on September 29. She gave a history of contact with the two sisters within 3 days of that date. The other 7-year-old girl became ill on October 8, and her sister, on November 21.

The mother and a relative of the first of the girls had typhoid fever several years ago. Stool specimens from both had been examined in October 1954 and found to be negative for organisms of the *Salmonella* or *Shigella* groups. A test of a specimen from the relative in August 1955 was also negative.

Both households in which the three typhoid fever cases occurred have outside plumbing, and general household sanitation is very poor.

Summary

Circumstantial evidence suggested that contamination of the water supply through outdoor plumbing was responsible for the spread of infectious hepatitis, diarrhea, and typhoid fever in a small area of Washington, D. C., in late 1954 and early 1955. Investigation showed that, although one outbreak of diarrhea was

probably waterborne, contact was the major factor in most cases of the three diseases.

The infectious hepatitis was confined almost entirely to white children under the age of 15 years. The rate of personal contact with prior cases was significantly higher for persons who had the disease than for those who did not. A nearly complete chain of contact among the patients was traced within the survey area.

Data on sleeping space per person indicated a relation between the incidence of secondary cases of infectious hepatitis and crowding.

An unexpectedly large number of persons who had once had typhoid fever were found in the survey area. Poor sanitary and plumbing conditions, as well as contact, were associated with three cases of typhoid fever reported in the fall of 1954.

. . .

Details of the study plan and procedures and the forms used in the surveys are available from the authors.

No Proof of Actual Harm Required In Water Pollution Abatement Action

The Appellate Court of Illinois recently held that, under a statute which defined pollution as including the "alteration of the physical, chemical or biological properties of water," the discharge by a municipality of untreated sewage into the Big Muddy River was subject to abatement by order of the Illinois State Sanitary Water Board on proof that such discharge adversely affected bacterial life normally present in the water. There was also testimony that the sewage discharge resulted in conditions detrimental to fish life.

The court rejected the argument that the board had no power to act except to abate a common law nuisance or without at least a showing of actual harm to fish or of human illness. Such restrictions, the court held, al-

though applicable to private suits, could not limit the board's powers to prevent pollution before actual harm resulted.

This is the first reported case involving the definition of "pollution" contained in the "Suggested State Water Pollution Control Act" (published by the Public Health Service in 1950), which was closely followed in the Illinois statute. *City of Murphysboro v. Sanitary Water Board of Ill.* 134 NE 2d 522 (4th Dist., Ill., 1956).

The "Suggested State Water Pollution Control Act" was endorsed by the Council of State Governments and recommended to the States in the council's "Suggested State Legislation; Program for 1951" issued in November 1950.

Sanitary Engineering Degrees Awarded in 1955

EDMUND J. LAUBUSCH, M.S., and
ARVEY F. LUDWIG, M.S.

FOR the academic year 1954-55, there were 141 graduates from undergraduate sanitary engineering courses in the United States. In this same period, there were 145 graduate degrees conferred: 134 master's and 11 doctor's. The academic year, July 1954-June 1955, covers degrees granted in August 1954, February 1955, and June 1955.

Mr. Laubusch, now with the Chlorine Institute, Inc., was formerly senior assistant sanitary engineer, and Mr. Ludwig is sanitary engineer director, Division of Sanitary Engineering Services, Public Health Service.

The institutions offering sanitary engineering training at various academic levels and the numbers of degrees conferred are shown in the table. Similar data for the 62-year period 1889-1950 are available in the literature (1).

Undergraduate Degrees

All but 12 of the 44 colleges and universities reporting the availability of undergraduate sanitary engineering training had graduates. For the academic years 1952-53 and 1953-54, the numbers of graduates were 216 and 164, respectively. The average number of graduates per year for the previous 5-year period, 1950-54, was 225.

Master's Degrees

Of the 134 master's degrees awarded in 1955, 100 were awarded to United States citizens. Twenty, or about 37 percent, of the colleges and universities reporting the availability of graduate sanitary engineering training at this academic level had no graduates. For the aca-

Engineering degrees awarded in 1955 to persons with sanitary engineering training, United States

Leaders (-----) indicate no courses offered at this level.

¹ Master's in engineering with major in sanitary engineering. ² Doctor's in civil engineering with major in sanitary engineering. ³ Master's in civil engineering with major in sanitary engineering. ⁴ Doctor's in sanitary engineering starting September 1955. ⁵ Has an undergraduate sanitary engineering curriculum. ⁶ Sanitary engineering courses are available as electives rather than as an option to the civil engineering program. ⁷ Master's in civil engineering with sanitary engineering electives or minor. ⁸ One "sanitary engineer" degree awarded (same as science degree except creative research not required). ⁹ One professional degree awarded; no thesis required. ¹⁰ Doctor's in engineering with specialization in sanitary engineering. ¹¹ Doctor's in municipal and sanitary engineering. ¹² Master's in municipal and sanitary engineering. ¹³ Also includes master's in civil engineering with major in sanitary engineering and master's in mechanical with major in sanitary engineering.

demic years 1952-53 and 1953-54, the numbers of graduates receiving master's degrees were 102 (20 by foreign nationals) and 120 (25 by foreign nationals) respectively. The average number of master's degrees conferred per year for the previous 5-year period, 1950-54, was 125.

Doctor's Degrees

Nine of the 11 doctor's degrees conferred during this period by four institutions were to United States citizens. Twenty-four other institutions offering sanitary engineering training at this academic level had no successful candidates this year. For the academic years 1952-53 and 1953-54, the numbers of graduates receiving

doctor's degrees were 5 (3 by foreign nationals) and 9, respectively. In the previous 5-year period, 1950-54, the average number of doctor's degrees conferred per year was 6.8.

Milk Sanitation Honor Roll for 1954-56

Thirty-four communities have been added to the Public Health Service milk sanitation "honor roll" and 69 communities on the previous list have been dropped. This revision covers the period from July 1, 1954, to June 30, 1956, and includes a total of 251 cities and 39 counties.

Communities on the "honor roll" have complied substantially with the various items of sanitation contained in the milk ordinance suggested by the United States Public Health Service. The State milk sanitation authorities concerned report this compliance to the Public Health Service. The rating of 90 percent or more, which is necessary for inclusion on the list, is computed from the weighted average of the percentages of compliance. Separate lists are compiled for communities in which all market milk sold is pasteurized, and for those in which both raw milk and pasteurized milk is sold.

The suggested milk ordinance, on which the milk sanitation ratings are based, is now in effect through voluntary adoption in 427 counties and 1,603 municipalities. The ordinance also serves as the basis for the regulations of 34 States and 2 Territories. In 11 States and the 2 Territories it is in effect statewide.

The ratings do not represent a complete measure of safety, but they do indicate how closely a community's milk supply conforms with the standards for grade A milk as stated in the suggested ordinance. High-grade pasteurized milk is safer than high-grade raw milk because of the added protection of pasteurization. The second list, therefore, shows the percentage of pasteurized milk sold in a community which also permits the sale of raw milk.

Although semiannual publication of the list is intended to encourage communities operating under the suggested ordinance to attain and

This compilation is from the Division of Sanitary Engineering Services of the Bureau of State Services, Public Health Service. The previous listing was published in Public Health Reports, March 1956, pp. 327-330. The rating method was described in Public Health Reports 53: 1386 (1938). Reprint No. 1970.

maintain a high level of enforcement of its provisions, no comparison is intended with communities operating under other milk ordinances. Some communities might be deserving of inclusion, but they cannot be listed because no arrangements have been made for determination of their ratings by the State milk sanitation authority concerned. In other cases, the ratings which were submitted have lapsed because they were more than 2 years old. Still other communities, some of which may have high-grade milk supplies, have indicated no desire for rating or inclusion on this list.

The rules for inclusion of a community on the "honor roll" are:

1. All ratings must be determined by the State milk sanitation authority in accordance with the Public Health Service rating method, which is based upon the grade A pasteurized milk and the grade A raw milk requirements of the Public Health Service milk ordinance. (A departure from the method described consists of computing the pasteurized milk rating by weighting the pasteurization plant rating twice that of the raw milk intended for pasteurization.)

2. No community will be included

on the list unless both its pasteurized milk and its retail raw milk ratings are 90 percent or more. Communities in which only raw milk is sold will be included if the retail raw milk rating is 90 percent or more.

3. The rating used will be the latest submitted to the Public Health Service, but no rating will be used which is more than 2 years old. (In order to promote continuous rigid enforcement rather than occasional "cleanup campaigns," it is suggested that when the rating of a community on the list falls below 90 percent, no resurvey be made for at least 6 months. This will result in the removal of the community from the subsequent semiannual list.)

4. No community will be included on the list whose milk supply is not under an established program of official routine inspection and laboratory control provided by itself, the county, a milk control district, or the State. (In the absence of such an official program there can be no assurance that only milk from sources rating 90 percent or more will be used continuously.)

5. The Public Health Service will make occasional check surveys of cities for which ratings of 90 percent or more have been reported by the State. (If the check rating is less than 90 percent, but not less than 85, the city will be removed from the 90-percent list after 6 months unless a resurvey submitted by the State during this probationary period shows a rating of 90 percent or more. If the check rating is less than 85 percent, the city will be removed from the list immediately. If the check rating is 90 percent or more, the city will be retained on the list for 2 years from the date of the check survey, unless a subsequent rating during this period warrants its removal.)

Communities awarded milk sanitation ratings of 90 percent or more, July 1954-June 1956

NOTE: In these communities the pasteurized market milk shows a 90-percent or more compliance with the grade A pasteurized milk requirements, and the raw market milk shows a 90-percent or more compli-

ance with the grade A raw milk requirements, of the milk ordinance suggested by the United States Public Health Service.

Note particularly the percentage of the milk pasteurized in the vari-

ous communities listed. This percentage is an important factor to consider in estimating the safety of a city's milk supply. All milk should be pasteurized, either commercially or at home, before it is consumed.

Child Guidance Clinic Policy and Practices

THIS REVIEW of the personal, physical, psychological, and social characteristics of patients seen in the Los Angeles Child Guidance Clinic attempts to ascertain whom the clinic served and to derive, as far as possible, some ideas of the problems most suitable for child guidance clinic services, the procedures of intake and of closing cases, and how worth while the work of the clinic seemed to be.

The 500 cases studied were divided into two groups: 450 successive cases for which full responsibility was taken by the clinic and 50 cases for which major responsibility was taken by some other agency. In the latter, known as cooperative cases, the major role of the clinic was that of consultant and, sometimes, provider of continued psychiatric treatment.

All evaluations of medico-psychiatric procedures were the responsibility of the psychiatrist, who had had a major administrative responsibility for overall policies of the clinic for many of the preceding years. The procedures of experienced social research were applied, and a rather large listing of problems by category was worked out.

Some of the more significant conclusions reached and further questions raised were:

1. About 12 percent of the cases were considered unequivocally successful and 47 percent, partially successful. Criteria applied were disappearance or diminution of symptoms, clarification of parent-child relationships, insight into problems by patient or responsible adults, and clarification of problems to agencies.

2. Sharp clarification of the basic orientation of the agency. Is it primarily medical or psychiatric or social casework? What evidence is there that the clinic team functioned to best advantage? The conclusion was that only about one-fifth of the cases clearly called for a team approach; the others seemed to warrant referral

to casework agencies, private psychologists, school clinics, or other facilities not involving the specialized expense and complexity of the child guidance clinic.

3. What should be the relationship of the child guidance clinic toward other agencies in the community? Integration into the work of a health and welfare agency? Or should it

Public Health

MONOGRAPH

No. 42

The accompanying summary covers the principal findings presented in Public Health Monograph No. 42, published concurrently with this issue of Public Health Reports. At the time of the study, the authors were with the Los Angeles Child Guidance Clinic, Los Angeles, Calif.

Readers wishing the data in full may purchase copies of the monograph from the Superintendent of Documents, Government Printing Office, Washington 25, D. C. A limited number of free copies are available to official agencies and others directly concerned on specific request to the Public Inquiries Branch of the Public Health Service. Copies will be found also in the libraries of professional schools and of the major universities and in selected public libraries.

Experimental Approach to DDT Toxicity

Many human health problems have been created with the introduction of chlorinated hydrocarbons as pesticides. Much interest has centered around food residues, since one common method of application of these insecticides has been deliberately to use their residue effect for pest control. Owing to previous experience with other types of insecticides having a residue effect, there is an extensive precedent for food sampling, chemical analysis, legislation, and field regulations. However, to do this intelligently, the magnitude of the problem has to be carefully defined.

Specifically, in regard to chlorinated hydrocarbons there is no argument that these compounds are dangerous and lethal when ingested in large amounts. The only difference of opinion relates to the exact level at which a given food residue becomes sufficiently large so that its potential hazard to man outweighs its value for insect control. The development of insect resistance and tolerance is likely to make this type of decision increasingly difficult. DDT (2,2 bis-(p-chlorophenyl)-1,1,1-trichloroethane) is a typical example of a chlorinated hydrocarbon in extensive field use. This was the compound selected for experimentation.

In view of the importance of safeguarding human life, while permitting agriculture to use these chemicals as indicated, it would appear that there is a need for more basic information on the physiological effect of human exposure to low doses of these compounds. One approach is to simulate the human experience by continuously feeding various levels of DDT incorporated into the diet of white rats. This method, even though representing a laboratory simplification of field conditions, creates new difficulties in the evaluation of the significance of tissue changes or biochemical abnormalities.

Ultimately, the extrapolation of animal studies to human medicine represents the most vexing problem of all.

Public Health

MONOGRAPH

No. 43

The accompanying summary covers the principal findings presented in Public Health Monograph No. 43, published concurrently with this issue of Public Health Reports. The senior author is with the National Cancer Institute, Public Health Service, Bethesda, Md.; and the junior authors are with the Technical Development Laboratories, Communicable Disease Center, Public Health Service, Savannah, Ga.

Readers wishing the data in full may purchase copies of the monograph from the Superintendent of Documents, Government Printing Office, Washington 25, D. C. A limited number of free copies are available to official agencies and others directly concerned on specific request to the Public Inquiries Branch of the Public Health Service. Ortega, Paul, Hayes, Wayland J., Jr., Durham, William F., and Mattson, Arnold: DDT in the diet of the rat. Public Health Monograph No. 43 (Public Health Service Publication No. 484). 27 pages. Illustrated. U. S. Government Printing Office, Washington, D. C., 1956. Price 30 cents.

remain somewhat isolated as a highly specialized technical service?

4. Who should refer cases to the clinic? Is it desirable to have parents apply directly for clinic service when only a very small number of cases can be served in a huge area? Or should referrals come through physicians or professional agencies in which some degree of preliminary screening has been done?

5. The question of the suitability of many cases for clinic service is raised since 31 percent of the cases were closed out for reasons which amounted to "against the advice of the clinic."

6. What evidence is there that cases referred on the basis of symptoms which fall into certain categories are more amenable to treatment than other cases? That is, are cases in which symptoms are concrete, specific items of undesirable behavior more treatable than those in which symptoms are described in terms of generalized abstractions or "cause"?

The study does not give any definitive answers but is believed to raise a number of significant questions, with sufficient data on many of them to provide a basis for further studies.

Confirm Efficacy of Salt and Soda Solution

Clinical tests have confirmed the earlier laboratory findings of three Public Health Service scientists, Dr. Sanford M. Rosenthal, Herbert Tabor, and R. Carl Millican, that oral consumption of salt and soda solution in large amounts is an effective emergency treatment for shock due to burns.

The tests were conducted in Lima, Peru, by Peruvian and American scientists, headed by Dr. Kehl Markley, under the sponsorship of the Public Health Service. Reporting in the *Journal of the American Medical Association*, August 11, 1956, they said no toxic effects from the use of the saline solution, even though it was administered in large amounts, were observed in any of the 193 severely burned patients.

A simple, effective procedure for treatment of shock, which so often kills victims of severe burns during the first 48 hours after injury, is particularly valuable in a major disaster. As the saline solution may be prepared easily of materials available in almost every home (table salt, baking soda, and tap water) the method may save many lives in disasters when skilled medical care is not promptly available.

Shock formerly caused countless deaths among victims of burns and other types of injury. During the past 20 years, intravenous injection of whole blood, plasma, or the so-called plasma extenders has proved effective

in preventing such effects of shock. The difficulties of intravenous therapy, however, are considerable, and they are overwhelming in a major disaster.

Even today, a high proportion of early deaths among victims of burns covering 10 percent or more of the body area is attributable to shock. The trauma induces a state of profound physical and mental depression, usually 3 to 5 hours following injury. Its chief features include the following: marked fall in blood pressure; feeble and rapid pulse; decreased respiration; a sudden and intense, although incomplete, suspension of vital body functions; and, sometimes, unconsciousness. The victim's skin is pale and clammy. In burns, loss of circulating body fluids sets up an immediate and pressing need for replacement.

The saline solution used during the clinical tests may be approximated, for emergency purposes, by dissolving a teaspoonful of table salt and one-half teaspoonful of baking soda in a quart of drinking water. The patient should be encouraged to drink as much as he can of this solution. Of course, liquids should not be given to persons who are unconscious or who cannot swallow. A victim of burns may require as much as 6 or 7 quarts or more during the first 12 hours following injury.

If nerve gases, incidentally or accidentally, contaminate public water supplies, the choice of methods for detection and decontamination will be crucial. Satisfactory methods for Sarin and Tabun are assured.

Nerve Gas in Public Water

By JOSEPH EPSTEIN, M.S.

WATER WORKS ENGINEERS, alert to the hazards of radiological, biological, and chemical warfare agents, must be concerned primarily, among the chemicals, with the nerve gases.

Many other chemical agents, because of intrinsically low toxicity if admitted orally, or because of rapid hydrolysis to relatively nontoxic products, are unlikely to appear in hazardous concentrations in a large volume of water. For example, consider hydrogen cyanide and cyanogen chloride, extremely toxic if inhaled. It would take 1 ton of either, uniformly dissolved in a 10-million-gallon reservoir, to reach a concentration of 25 p.p.m. This concentration in water is considered physiologically tolerable for the average man if consumed in normal quantities for a 1-week period (1).

More specifically, it would take 1.66 tons of either chemical to reach a 25 p.p.m. concentration in Baltimore's 16-million-gallon capacity Montebello Reservoir; 43,200 tons in Boston's 415-billion-gallon Quabbin Reservoir; 13,500 tons in New York City's 130-billion-gallon Ashokan Reservoir.

In reservoirs of less than 1-million-gallon capacity, the margin of safety owing to dilution is, of course, reduced.

Mr. Epstein is chief, Sanitary Chemistry Branch, Biochemical Research Division, Chemical Warfare Laboratories, Army Chemical Center, Md.

Even the highly toxic and vesicant lewisite, when viewed in this light, presents little hazard as a water contaminant. Lewisite hydrolyzes almost instantaneously in water to the mildly vesicant oxide. The toxicity of the oxide is apparently due to its trivalent arsenic content, which may be oxidized with ease by chlorine or other oxidizing agents to the less toxic pentavalent state. In fact, trivalent arsenic becomes converted to the pentavalent state upon standing in water.

If water containing lewisite is chlorinated according to standard procedures for bacterial purification and is used for not more than 1 week to avoid possible cumulative effects, as much as 20 p.p.m. of lewisite can be tolerated in drinking water (1). Calculation of the quantities of lewisite required to produce concentrations of physiological significance in the bodies of water mentioned previously quickly reveal the improbability that significant contamination of large bodies of water by lewisite will occur as a result of general chemical warfare.

By similar reasoning, the danger of contamination of fairly large bodies of water during general warfare by agents such as phosgene, chloropicrin, chlorine, chloroacetophenone, diphenyl-chlorarsine, and the like is not particularly great.

Although it may appear that the danger of contamination of water supplies by most chemical agents will be small, nevertheless, the possibility of contamination to dangerous levels is a contingency which requires knowledge of the

Briefly, our experiments used 178 male and 104 female white rats fed levels of DDT from less than 0.05 parts per million of the poison in the diet as a whole up to 5,000 p.p.m. from periods of 2 weeks to 20 months. The animals were studied for clinical manifestations of toxicity, for gross and microscopic tissue changes, for rapidity of development and permanence of histopathology, and for recovery on a DDT-free diet after previous exposures. Special biochemical tests were used for body fat and tissue storage of DDT, as well as for liver function determinations. Certain laboratory devices

such as serial liver biopsy and study of different chemical isomers of this molecule added some supplementary information.

To summarize the results of the experiment, the salient feature among numerous other data was that cellular alterations could be demonstrated in the liver of rats fed DDT at levels as low as 5 p.p.m. in the diet. However, the findings indicated that stress should be placed on the mildness of these changes, their ready reversibility, and their imperfect correlation with liver function or with the clinical symptomatology of DDT.

technical publications

Infectious Hepatitis in New Delhi

Report of the Committee Investigating the Epidemic of Jaundice, December 1955-January 1956

Public Health Service Reprint from the Hindustani Standard, February 18, 1956. 28 pages. Mimeographed.

The text of a report by the committee which investigated the recent outbreak of infectious hepatitis in New Delhi, India, has been reproduced and is available in limited quantities from the Water Supply and Water Pollution Program, Robert A. Taft Sanitary Engineering Center, Cincinnati 26, Ohio, Attention: Dr. R. L. Woodward.

The report documents the first waterborne infectious hepatitis outbreak associated with a water supply treated in a modern water treatment plant providing coagulation,

rapid sand filtration, and chlorination. Bacteriological tests for coliform bacteria showed no evidence of contamination.

The report holds that the authorities concerned had taken the necessary steps to guard against bacterial contamination of the water but not against viral infection.

Design for Statewide Nursing Surveys

Public Health Service Publication No. 460. 88 pages. 50 cents.

The latest techniques for finding the extent of nurse shortages and removing some of the causes are contained in a new manual prepared by the Division of Nursing Resources. Design for Statewide Nursing Surveys tells how to organize a survey committee, how to obtain community support for making surveys, and how

to gather and analyze information on local supply and nurse shortages.

A section on reappraisal of nursing needs and resources tells how to set up a plan for periodic fact finding after the basic survey has been made. Examples of progress in some 40 States which have made preliminary surveys, samples of the letters, forms, and tables used for compiling the facts, and suggested guides for evaluating adequacy of nurse supply are given.

This section carries announcements of all new Public Health Service publications and of selected new publications on health topics prepared by other Federal Government agencies.

Publications for which prices are quoted are for sale by the Superintendent of Documents, U. S. Government Printing Office, Washington 25, D. C. Orders should be accompanied by cash, check, or money order and should fully identify the publication. Public Health Service publications which do not carry price quotations, as well as single sample copies of those for which prices are shown, can be obtained without charge from the Public Inquiries Branch, Public Health Service, Washington 25, D. C.

The Public Health Service does not supply publications issued by other agencies.

In the absence of large quantities of salts, the half-life ($t_{1/2}$) of Sarin in water at 25° C. (77° F.) at constant pH in the pH range of 6.5 to 13.0 can be estimated from equation 2.

$$t_{1/2} = (5.4 \times 10^4) (10^{\text{pH}}) \quad [2]$$

Thus at pH 7, the half-life of Sarin in water at 77° F. is 54 hours; at pH 8, 5.4 hours; at pH 9, 0.54 hours, and so forth. Between pH 4.0 and 6.5, the hydrolysis rate of Sarin is at a minimum; its half-life in this range is approximately 175 hours. It is evident from equation 2 that above pH 6.5 the rate of hydrolysis increases 10 times per unit increase in pH. Below pH 4.0, the rate increases approximately 10 times per unit decrease in pH. At a given pH, the hydrolysis rate will vary by a factor of approximately 2 for each change of 10° C. The relationship between the half-life of Sarin in dilute aqueous solution at 25° C. and the pH of the water is shown graphically in figure 1.

Figure 1. The relationship between the half-life of Sarin at 25° C. and the pH of water.

The rates of hydrolysis which one might estimate from the use of equation 2 presupposes that the pH will remain constant during the time the Sarin is undergoing hydrolysis. For small concentrations of Sarin, that is, up to 5 p.p.m., in waters containing some buffer capacity, a constant pH will, in all probability, prevail. However, in the absence of significant buffer constituents in the water and at the higher concentrations of Sarin under discussion, the effect of the acidity produced by the hydrolysis may be very important to the stability of Sarin in water. In slightly alkaline water of low buffer capacity, the production of acids caused by a limited hydrolysis of Sarin can lower the pH to the range in which Sarin exhibits maximum stability. Thus, under certain conditions, the hydrolysis of Sarin may produce materials which retard subsequent hydrolysis. In effect, Sarin can stabilize itself.

The rate of hydrolysis of Sarin is accelerated by anions other than hydroxyl ions. The hydrolysis of Sarin is more rapid in the presence of such anions as trivalent phosphate or carbonate ions than might be predicted from the pH of the solution. On the other hand, the hydrolysis rate in the presence of rather large quantities of sulfate, chloride, or nitrate does not materially differ from the rate in water devoid of salts at the same pH. However, the quantities of the catalytic anions, for example, trivalent phosphate, needed to produce appreciable effects upon the hydrolysis rate, will not normally be encountered in water supplies.

Depending upon the pH of the water, some metal ions have strong catalytic effects upon the rate of hydrolysis of Sarin. Cupric, manganous, magnesium and calcium ions, to mention a few, are very effective catalysts, whereas sodium and potassium ions are virtually ineffective. Cupric and manganous salts are more effective in neutral or slightly acidic waters, whereas magnesium and calcium are more effective in alkaline waters.

At pH 6.5 and 25° C., where magnesium salts show practically no effect upon the hydrolysis rate of Sarin, the half-life of Sarin in water containing only 1 p.p.m. cupric ion is 2 hours as compared to a half-life of approximately 175 hours in the absence of the metallic ion. At pH 8.5 and 25° C., on the other hand, where

behavior of chemical agents in water and of methods of water purification or removal of the agents from water.

Quantitative data applicable particularly to the treatment of water contaminated with all but the more recent nerve gases are available (2,3). For a general history of the nerve gases and information relative to the mechanism of action, effects, and treatment of nerve gas poisoning, the reader is referred to articles by Holmstedt (4), Krop and Kunkel (5), Grob and Harvey (6), Wood (7), and Krop and Loomis (8).

In discussing the properties and behavior of the nerve gases Tabun and Sarin in dilute aqueous solution, the concentrations will be of the order of $1-2-10^{-4}$ M or about 15-30 p.p.m., unless otherwise noted. The structures and chemical and common names of Tabun and Sarin as well as DFP, an agent similar to Sarin, are shown below.

Toxic Levels of Nerve Gases in Water

The level of tolerance to Sarin in water has been set at 0.5 p.p.m. with the limitation that the total volume of water taken per day will be no greater than 5 liters and that the period of ingestion will be no more than 3 days (1). This sets 2.5 mg. of Sarin as the maximum intake in a 24-hour period, and 7.5 mg. the maximum in a 3-day period. Except for the unlikely case of recontamination, the concentration on the second and third day will probably be somewhat lower than the initial concentration of 0.5 p.p.m., due to the natural and spontaneous hydrolysis of the nerve gas. The products of

hydrolysis, from experimentation with rats, can be considered nontoxic.

By comparison of the toxicities to rats, it is estimated that Tabun is about one-fourth as toxic as Sarin via the oral route. A reduction of the "tolerance level" by 10 to 100 times may be advisable when infants or small children are to be the consumers. The quantities of nerve gases, then, which are needed to bring the level of contamination to a tolerance level for reservoirs of medium capacity do not appear to be of a magnitude sufficient to make contamination improbable.

In fact, it must be concluded that it is probable that water will become contaminated to hazardous levels if the nerve gases Sarin and Tabun are employed during warfare.

Hydrolysis of Sarin

Qualitatively, the behavior of Sarin in water is very similar to that of DFP whose hydrolysis in dilute aqueous solution has been thoroughly investigated (9). Like DFP, Sarin hydrolyzes to form two acids (equation 1), and the hydrolysis is catalyzed by both acids and bases, although bases are more effective catalysts.

The rate of hydrolysis is dependent not only upon the pH but also upon the type and quantity of dissolved solids in the water and the temperature of the water.

Common Name	Chemical Name	Structure
Tabun.....	Dimethylamido ethyl phosphorocyanidate.....	$\begin{array}{c} \text{O} \\ \parallel \\ (\text{CH}_3)_2\text{N}-\text{P}-\text{CN} \\ \mid \\ \text{O C}_2\text{H}_5 \end{array}$
Sarin.....	Isopropyl methylphosphonofluoridate.....	$\begin{array}{c} \text{CH}_3 \\ \mid \\ \text{HC}-\text{O}-\text{P}-\text{F} \\ \mid \qquad \qquad \mid \\ \text{CH}_3 \qquad \qquad \text{CH}_3 \end{array}$
DFP.....	Diisopropyl phosphorofluoridate.....	$\begin{array}{c} \text{CH}_3 \\ \mid \\ \text{HC}-\text{O}-\text{P}-\text{F} \\ \mid \qquad \qquad \mid \\ \text{CH}_3 \qquad \text{OCH}(\text{CH}_3)_2 \end{array}$

may serve to warn that contamination has occurred. An abnormally high fluoride ion concentration in water should arouse the suspicion of the operator as to the potability of the water. However, since only 13 percent of the Sarin molecule after complete decomposition is fluoride ion, probably only when relatively high concentrations are in the water supply would the water be suspected because of fluoride ion concentrations.

The existence of fluoride ion and the low pH can only serve to point out that undecomposed Sarin may be present, not that it is. The same limitations apply to detection methods via the phosphorus moiety of the molecule.

It appears reasonable to conclude that dangerous concentrations of Sarin may remain undetected if only the nonspecific pH and chlorine demand tests and the tests for the fluoride ion and phosphorus are used. However, judicious choice of methods for estimation of fluoride ion concentrations and correlation of these tests with others such as pH and the alteration of the pH of the water observed at various time intervals may be helpful in the detection and estimation of Sarin.

Depending upon the method used for estimation of fluoride ion, one may obtain varying values for fluoride ion in waters containing both unhydrolyzed and hydrolyzed Sarin. If the methods recommended for fluoride in Standard Methods for the Examination of Water and Sewage, Ninth Edition, 1946, are used, then the total fluorine of the hydrolyzed and unhydrolyzed Sarin will be determined, since under the conditions of acidity required for this test, the bound fluorine in Sarin will be converted to ionic fluorine in a few minutes and thus will be determined as ionic fluorine. On the other hand, if fluoride ion is determined in neutral solution, and in the absence of hydrolytic catalysts, then only the fluoride ion present at the time of the test will be determined.

Both Sarin and Tabun in the presence of their hydrolysis products may be detected and estimated rapidly and in very low concentration by their reaction with benzidine or *o*-tolidine and alkaline peroxide solutions (12). By means of this reaction, the author and co-workers have been able to estimate quantitatively as little as 0.1 p.p.m. of Sarin in water, and the method

can probably be modified to increase the sensitivity.

The test has been adapted for field use and is included in two Chemical Corps water testing kits described in technical bulletins (13, 14).

The response of three small species of fish, the fathead minnow (*Pimephales promelas*), the green sunfish (*Lepomis cyanella*), and the goldfish (*Carassius auratus*) to Sarin and Tabun are useful to the detection and, in some cases, estimation of small concentrations of nerve gases in water. The approximate LC₅₀ (concentration of agent required to kill 50 percent of the test animals) for exposures of 10, 15, and 20 minutes at 70°–75° F. for the three species are shown in table 1.

It is possible to decrease the concentration of the nerve gas necessary to produce an LC₅₀ by increasing the exposure time, but with increased exposure times, the effect of the pH of the water becomes very important due to hydrolysis rates of the agents. Thus, for a 24-hour period, the LC₅₀ of Sarin for the sunfish is 2 p.p.b. (.002 p.p.m.) if the water is kept at pH 6.5 (minimum hydrolysis), but 9.5 p.p.b. at pH 8.0. Similar data have been obtained with the other species for Sarin and Tabun.

The LC₅₀ values are increased if the temperature of the water is lowered. For a change of approximately 25° F., the LC₅₀ values for a 10-minute exposure should be multiplied by 6 to 8 for the three species.

Table 1. Approximate LC₅₀ of Sarin and Tabun (p.p.m.) for fish at 70°–75° F., by various exposure times

Fish species	Tabun			Sarin		
	Minutes of exposure			Minutes of exposure		
	10	15	20	10	15	20
Green sunfish.....	1.5	1.0	0.70	0.35	0.23	0.27
Fathead minnow.....	1.5	.9	.60	.63	.40	.3
Goldfish.....	2.4	1.7	1.3	.93	.6	.5

Decontamination

On the premise that decontamination procedures should reduce the level of Sarin and

the cupric ion is ineffective (due presumably to its insolubility) the half-life of Sarin may be decreased from 1.7 hours to 0.5 hours by the addition of 100 p.p.m. magnesium ion. The proportional effectiveness of magnesium ion is greater at alkalinities above pH 8.5, but is less necessary because of the effectiveness of hydroxyl ion alone at a higher pH.

Thus, in waters of high magnesium or calcium ion content, or in waters containing even trace quantities of some heavy metal ions, the hydrolysis rate of Sarin may be much more rapid than that predicted by equation 2. In most natural waters, however, the quantity and type of dissolved solids are such that prediction of the hydrolysis rate may be made from equation 2, provided, of course, that the pH is maintained constant during the hydrolysis.

Hydrolysis of Tabun

The hydrolysis of Tabun, like that of Sarin and DFP, is catalyzed by acids and bases, and bases are more effective than acids (10). Unlike Sarin and DFP, whose products of hydrolysis are independent of the catalyst used, Tabun is destroyed by attacks upon different parts of the molecule by acid and base, and the products of hydrolysis are different. In alkaline solution, the phosphorus to cyanide linkage is cleaved, resulting in the formation of a substituted phosphonate and sodium cyanide. In acid solution, the Tabun molecule is cleaved between the phosphorus and nitrogen. Both attacks result in destruction of the toxic properties of Tabun. (See below.)

In alkaline solution, the formation of acid tends to lower the pH of the solution; in slightly acid medium, the hydrolysis products are one acid and one base, and the pH remains constant.

From the data of Larsson (10) and Holmstedt (11), it appears that the rate of hydrolysis of Tabun at the P—CN bond is for all practical purposes independent of the hydroxyl ion concentration between the pH range of 4.0 to approximately 8.5. The half-life of Tabun in this pH range at 20°–25° C. is 2–4 hours.

Detection

Although a nerve gas attack would alert water works personnel, Sarin in water in concentrations of at least 35 p.p.m. is not detectable by odor or taste. Water containing concentrations of the hydrolysis products of Sarin as high as 200 p.p.m. was acceptable to rats. However, Tabun, which possesses a fruity odor, is detectable by smell in rather low concentrations. Furthermore, suspicion as to potability of water supply would be aroused by the odor of hydrocyanic acid which is formed by the hydrolysis of Tabun. Unlike Sarin, Tabun, through its released cyanide, will alter the "chlorine demand" of a water.

The uptake of chlorine in the reaction with Tabun will depend upon whether the chlorinating material is hypochlorite or chloramine. The chloramines will react only with cyanide ion which becomes available as a result of the hydrolysis of Tabun. The uptake of chlorine when hypochlorite is one of the reactants is also due to its reaction with cyanide, but apparently hypochlorite ion catalyzes the decomposition of Tabun to form cyanide so that, in effect, the uptake of chlorine is due to the Tabun as well as to the hydrolysis product.

If appreciable quantities of Sarin have hydrolyzed, and the contaminated water if of low buffer capacity, the low pH of the water, resulting from the acidic hydrolysis products,

Chlorine as hypochlorite will destroy Tabun, and the cyanide produced upon hydrolysis of Tabun will consume the chlorine.

Satisfactory procedures for decontamination of Sarin have been developed, utilizing the catalytic properties of hypochlorite. In field trials, HTH was used as the source of hypochlorite and, because rapid decontamination was desired, 100 p.p.m. chlorine was used. Following decomposition, the hypochlorite concentration was reduced to less than 1 p.p.m. by treatment with activated carbon.

Another satisfactory procedure for decontamination proved by field trials is to raise the pH of water to approximately 10.0 with soda ash, slaked lime or magnesium hydroxide, allow the Sarin or Tabun to hydrolyze, and when tests indicate that the concentration of the nerve gas is 0.1 p.p.m. or less, use a coagulant such as ammonium alum or ferric chloride, filter and

chlorinate. The rate of hydrolysis is followed by the test methods described (14) and the quantity of alkaline material to be added is regulated by the rate of hydrolysis. The alum or ferric chloride function not only as coagulants but also to reduce the pH of the water to normal acidities. Water treated by either procedure is potable and palatable.

Conclusion

From the preceding discussion, it appears reasonable to conclude that, in the event of general chemical warfare, the nerve gases Tabun and Sarin must be considered potential water contaminants because of the very small quantities of these agents required to produce toxic symptoms from ingestion. The hazard due to Tabun, however, is lessened somewhat because of its ease of detection in water by taste, odor, and chlorine demand test. Sarin presents a more difficult problem inasmuch as specific detection methods are necessary. Once detected, both Sarin and Tabun can be rapidly destroyed by simple decontamination procedures.

Figure 2. The relationship between the half-life of Sarin at 25° C. and the pH of water for different concentrations of free chlorine.

Tabun concentration to 0.1 p.p.m., field tests have shown that coagulation with ammonium alum, followed by filtration through diatomite or sand filters is not an effective decontaminating procedure. A procedure involving the use of ferric chloride as coagulant and powdered limestone as coagulant aid, followed by filtration through diatomite filters is also ineffective. These materials are used in the Corps of Engineers Mobile Water Purification Unit (15).

Approximately 62 pounds of carbon would have to be added to each 1,000 gallons of water to reduce the concentration of 30 p.p.m. to 0.1 p.p.m. A smaller total dose of carbon can accomplish the same objective if a multiple treatment procedure is applied. However, the time involved and the multiplicity of operations make such a procedure objectionable.

Sarin in water is rapidly hydrolyzed by the catalytic action of strongly basic ion exchange resins, such as Amberlite IRA-400 and Nalcite SAR and strongly acidic cationic resins such as Dowex 50 and Amberlite IR-112. The anionic resins are more effective, and function not only as catalysts, but also remove the hydrolytic products. In doing so, however, the resins lose their available hydroxyl ion and ultimately their ability to catalyze the hydrolysis.

Furthermore, in water of appreciable dissolved solid content, the anions of the salts replace the hydroxyl groups in the resin (and cations, the hydrogen ions of the cationic resins) resulting in a decreased efficiency of the resin, since the efficiency is related to the number of available hydroxyl or hydrogen ions in the resin. The use of resins for large scale water decontamination is not economically feasible.

At least two feasible methods for the destruction of Tabun and Sarin in water supplies are available. Both methods are based upon an acceleration of the normal hydrolysis rate. The methods involve chlorination or alkalization.

Chlorine will not react with Sarin, but hypochlorite ion is a very effective catalyst for the hydrolysis of both Sarin and Tabun. Compounds containing combined chlorine, such as chloramine T, on the other hand, exert practically no catalytic action. Table 2 shows the half-life of Sarin in water at approximately

Table 2. Half-life of Sarin ($2 \times 10^{-4}M$) in water in the presence of free chlorine

Temperature	pH	p.p.m. Cl_2	Half-life in minutes
77° F. -----	6	200	11
	7	25	13
	8	9	12

36°-37° F. -----	6	200	38
	7	100	12
	8	100	3
	9	50	4

77° F. and 35° F. at various pH's and in the presence of free chlorine, added as high test hypochlorite (HTH).

The importance of pH in this reaction is seen from the figures shown in table 2 on experiments at 77° F. Only one-eighth of the chlorine concentration was required at pH 7.0 as was required at pH 6.0 to give approximately the same rate of destruction. Approximately one-third the concentration of chlorine was required at pH 8.0 to produce the same effect at pH 7.0, and so forth. It can also be seen by comparing the half-lives of Sarin in the presence of equal concentration of chlorine and at the same pH but at two different temperatures, for example, pH 6, that the rate of destruction is approximately doubled for each rise of 10° C.

Where time of treatment can be extended to several hours, much lower concentrations can be used to produce effective decontamination. For example, by maintaining the water at pH 8.0, addition of 5 p.p.m. chlorine will reduce the concentration of Sarin from 30 to 0.1 p.p.m. in approximately 3 hours. Figure 2 shows half-life of Sarin at 25° C. at pH ranges between 6 and 9 in the presence of different concentrations of free chlorine.

A dosage of chlorine to be added to a water supply may be calculated from the values given in figure 2, a knowledge of the concentration of Sarin in the water, the temperature and pH of the water. The action of hypochlorite may be completely inhibited, however, if amines or ammonium salts are present in the water because of the very rapid reaction of hypochlorite with the nitrogen compounds to form chloramines (16) which are catalytically inactive.

Present Status of Controlled Fluoridation in the United States

CONTROLLED water fluoridation for the prevention of dental caries started in 1945 with study projects in three communities—Newburgh, N. Y., Grand Rapids, Mich., and Southbury Training School in Connecticut. The study projects were a natural outgrowth of earlier epidemiological research in cities where fluoride has been present naturally in the water supply, and which demonstrated the inverse relationship between fluoride-bearing water and dental caries experience.

Reports of lowered caries incidence in the study communities were published in 1950 (1-3). As a result of these and other studies, the fluoridation of water supplies was endorsed by national health organizations and the practice adopted by many communities.

Summarized is the present status of controlled water fluoridation in the United States. The summary data include the number of communities, water supply systems, and population served by fluoridated water; the date the procedure was instituted; ownership of the water plant, and authorization for fluoridation. These data are presented primarily as reference material.

From 1945, when controlled fluoridation was introduced, through May 2, 1956, 1,352 communities served by 727 water supply systems instituted fluoridation (table 1). Sixty-six com-

munities (5 percent of the total) served by 54 water supply systems discontinued fluoridation. Of these, 7 communities, each one its own water supplier, reinstituted the procedure.

By May 2, 1956, a net total of 1,293 communities with 26 million people were served by 680 water supply systems to which fluoride had been added.

The annual increment in the number of communities and water supply systems in which fluoridation was initiated, discontinued, and reinstituted and the population they serve is shown in table 2. The greatest increase in the initiation of fluoridation occurred during 1952. Subsequently, annual increments in number of communities, water supply systems, and population have been at a lower level.

Table 3 shows the number and percentage of communities in each of 11 population groups using fluoridated water at the end of 1955.

Of the 1,255 communities using controlled fluoridation at the end of 1955, nearly 30 percent are under 1,000 in population, or of size not specified. Most of the latter are quite small since no population figures were available from Bureau of the Census sources. A little more than 30 percent of communities using fluoridation range in size from 1,000 to 5,000 population. Another 30 percent are between 5,000 and 50,000 population. The remaining 6 percent are over 50,000 in size.

When these figures are compared with the total number of communities of given size, nearly 45 percent of the communities of 500,000 population or over are fluoridating their water supplies, and from 20 to 30 percent of the com-

The Mayo Memorial

Forming the heart of what is virtually a complete medical center on the University of Minnesota campus is the recently completed Mayo Memorial. The university's School of Public Health occupies 2½ floors of the new building's 14-story tower section.

The Mayo Memorial, which was dedicated on October 21, 1954, is the fulfillment of an idea begun more than a decade ago. In 1939, shortly after Doctors Charles H. and William J. Mayo had died, the Governor of Minnesota appointed a Mayo Memorial Commission to propose an appropriate monument. After considering many projects, the commission agreed that a center for teaching and research as a building of the University of Minnesota Medical Center would be the most fitting memorial. During their lifetime, the Mayo brothers had devoted much time, interest, and aid to the work of this institution.

A Committee of Founders started the project on its way. Funds were raised by legislative appropriation, public subscription, and grants from public and private agencies.

Construction was started in 1951 and completed in the early autumn of 1954.

The new building brings together the facilities of the School of Public Health formerly scattered in several university buildings. On the 11th floor are laboratories, offices, and classrooms for work in environmental sanitation and epidemiology. The 12th floor houses facilities for biostatistics, health education, and the course in hospital administration. The public health nursing unit, offices for the non-professional health and hygiene courses, and other offices are located on the 13th floor, which the school shares with the medical school administration. Conference and reading rooms are provided on each of the three floors used by the School of Public Health.

In addition to the tower section, the Mayo Memorial has three 6-story wings that connect with existing hospital and medical school buildings. The building has facilities for education, research, and service in connection with various departments of the medical school.

using central water supplies, were drinking water with an adjusted fluoride content.

During the last few years, the number of people drinking fluoridated water has increased by about 4 million persons a year.

There is every reason to believe that this rate of increase will not decline and may very well become greater. However, as of May 1956 only 6 percent of the towns and villages of under 10,000 population had fluoridation, even though

munities of 10,000 to 50,000 population. For communities of less than 10,000 population, the percentage of fluoridation ranges from 4 to 14 percent. The proportion of communities that have instituted controlled fluoridation increases almost directly with grouped community size.

Public or private ownership of water supply facilities and authorization by which fluoridation was instituted, by grouped size of community, are shown in table 4.

It is interesting to note that of the 1,255 places with fluoridation as of December 31, 1955, more than a thousand owned their own water plants, and in 160 places the plants were under private ownership. Of the privately

owned plants, 68 percent were in places of under 10,000 population. Distributed on the basis of size of towns, however, 17 percent of the places under 10,000 population and 9 percent of the towns over 10,000 had privately operated water plants.

Table 4 also shows that in almost all communities the problem of whether or not to fluoridate is decided by the governing body. In only 6 percent of the communities was the question of fluoridation decided by referendums.

This census shows that in May 1956, after more than 10 years of water fluoridation, approximately 26 million people in about 1,300 communities, or roughly 1 out of every 4 people

Analysis of a Hospital Consultation Program

By HELEN M. WALLACE, M.D., MARGARET A. LOSTY, R.N., ROBERT S. SIFFERT, M.D.,
JEROME S. TOBIS, M.D., and MIRIAM LENDING, M.D.

APPRAISAL of the effectiveness of individual programs is one of the basic needs in public health administration. All too frequently programs are initiated without an accompanying plan for evaluation. Or they are perpetuated without critical review and analysis to determine whether the originally planned objectives are being achieved. While it is not always easy to stimulate the development of new programs, sometimes it may be equally difficult to discontinue or modify old programs that prove to be partially or totally ineffective; frequently the underlying reason is the lack of substantiating facts of an evaluative nature.

Evaluation of public health programs should provide answers to two basic questions: (a) Is the program making a significant contribution toward improving the health of the public served? (b) Is the program making good use of the tax funds expended for the purpose? It is logical that if the answers to both ques-

tions are affirmative an existing program should be continued. If the answers are negative, the program should be reviewed carefully and either modified significantly or discontinued.

Since 1952 the bureau for handicapped children of the New York City Department of Health has provided consultation to hospitals participating in the health department's program for orthopedically handicapped children. To assess the value of this hospital consultation program, we have examined the results thus far and are reporting the findings.

Background Information

The New York City Department of Health now spends approximately \$2 million annually for the hospital and convalescent care and rehabilitation of children with many other types of handicaps besides orthopedic—congenital cardiac, orthodontic, plastic surgical, hearing, cleft palate, epilepsy, drug addiction, visual, and miscellaneous types. Within this broad diagnostic list, the orthopedic category remains one of the larger groups because it represents the original program for handicapped children in New York City. Some of the other categorical programs are only a few years old. The bureau staff has developed hospital consultation for most of these categorical groups.

Hospital consultation has been carried on for many years in the fields of epidemiology and maternal and newborn care and for a shorter time in the field of general hospital care (because of the Hill-Burton Act). But to our knowledge the hospital consultation program

Dr. Wallace is professor of maternal and child health, University of Minnesota School of Public Health. At the time of this study she was director of the bureau for handicapped children, New York City Department of Health. With the bureau are Miss Losty as hospital nursing consultant, Dr. Siffert, senior orthopedic consultant, Dr. Tobis, consultant in physical medicine and rehabilitation, and Dr. Lending, pediatric consultant. Herbert Rich, senior statistician of the bureau of records and statistics, assisted in the statistical presentation.

¹ Presumably under 1,000. The names of the towns are known, but their populations are not reported.

some 45 percent of the cities of more than 500,000 population were using fluoridated water. In numerical terms, this means 10 cities of over 500,000 persons do not have fluoridation and some 16,000 communities of under 10,000 population are not using fluoridated water.

from failure to consider all his needs—social, psychological, and followup, as well as pediatric and therapeutic. Improvements in outpatient service only were recommended 63 times and carried out 16 times (25 percent). The most frequent recommendation, that of instituting an appointment system, was not applied in any hospital. Implementation was obtained in approximately one-third of the recommendations for (a) a separate children's orthopedic clinic; (b) an effective followup of children failing to keep clinic appointments; and (c) for developing clinic staff conferences. In seven hospitals it was recommended that, for the convenience of the child and his mother, cast changes, where indicated, be performed at the time of the clinic visit instead of requiring another clinic visit on another day; almost three-quarters of the hospitals adopted this procedure.

Two major recommendations applied to both the inpatient and outpatient services. One consisted of the referral of patients to the voluntary public health nursing agencies in the community for home followup, public health nursing supervision, and physical therapy. This recommendation was adopted in two-thirds of the instances. The other consisted of setting up a unit system of records in the hospital to provide continuity of recorded information in the hospital setting. This recommendation was carried out by 39 percent of the hospitals.

Personnel

A total of 95 recommendations pertained to personnel caring for orthopedically handicapped children and were carried out in 37 instances, or 39 percent (table 2).

The frequency of personnel recommendations

for handicapped children in New York City is the first of its kind in the field of chronic disease in children.

The details of this program have been presented in another report (1), but briefly the hospital consultation program functions in the following manner:

1. An advisory committee recommends a set of standards.

2. A team of specialists surveys the institutional services in the particular fields concerned.

3. The team then transmits a letter of recommendations to the key personnel of the institution.

4. At a postsurvey conference, the specialists discuss the recommendations with the key members of the institutional staff.

5. The survey team conducts followup activities, depending on the needs and requests of the individual institutions.

In the bureau's consultation program in the orthopedic field, the services of 25 children's hospitals have been surveyed by a team composed of an orthopedic surgeon, a pediatrician, a physiatrist, a hospital nursing consultant, and a medical social worker. Letters of recommendation have been sent to the staffs of 24 hospitals, and postsurvey conferences have been held with the staffs of 22 hospitals. Of the 25 hospitals, 15 are large general hospitals; 5 are specialty hospitals devoted predominantly or exclusively to the care of the orthopedically handicapped; 4 are for chronic diseases and 1 for communicable diseases.

We have taken as the endpoint in this analysis the information collected at the postsurvey conferences.

Survey Recommendations and Results

The survey data have been subdivided into four headings for presentation: (a) policies and procedures; (b) personnel; (c) accreditation; (d) physical plant and equipment. These four headings represent the great majority of all the recommendations made. To arrive at a simple summary of the survey data, a function "hospital-items" has been used. It is the product of the number of hospitals times the number of items evaluated, recommended, or adopted in any particular subgroup. Thus,

in the policies and procedures group, 25 hospitals were surveyed and 15 items evaluated, that is, 375 hospital-items. In all, 189 hospital-items were recommended under the policies and procedures heading (50 percent of the 375 hospital-items evaluated in this category); 95 pertained to personnel (38 percent); 13 to accreditation (17 percent); and 12 to physical plant and equipment (24 percent).

Policies and Procedures

In the policies and procedures area a total of 91 recommendations pertained to inpatient service only, 63 recommendations to outpatient service only, and 35 recommendations to both services. Thirty-five percent of the recommendations were adopted by the hospitals (table 1).

For inpatient service, the recommendations of individual items varied in frequency from advising the team approach to patient care in 24 hospitals to advising improvement of social service and occupational therapy notes in 5 hospitals. Implementation of recommendations by the hospitals varied from 60 percent for improvement in social service records to 29 percent for developing a team approach to patient care. Changes were made most frequently as a result of the recommendations in the most specific, simplest, and superficial areas, such as recording of patient information. The least frequent implementation occurred in the conceptual area of patient care—the team approach, which signifies that the optimum care of the handicapped child requires the participation of many professional disciplines working together as a team.

Only about one-third of the hospitals in which the recommendations concerned the inpatient service improved their pediatric supervision of children and improved their pediatric notes. Also only one-third of the hospitals liberalized visiting hours for the parents of the children. Although this type of recommendation does not deal specifically with the orthopedic care of the child, its importance should not be minimized since the consideration of the "child" is as important as the consideration of the "patient." Too often the child leaves the hospital with a healed operative scar but with an unhealed scar resulting

consolidation of the physical location of the orthopedically handicapped children from six different places within the hospital into one central service; provision of a modern operating room, more adequate facilities for physical therapy, and a more suitable plaster room; and removal of an "isolation cubicle" from the children's ward. The recommendations for the outpatient service include: more space in general, more examining space, more space for physical therapy activities, and more privacy for patient examination and interpretation.

Discussion

The results of the first survey of the children's hospital orthopedic services, the transmission of postsurvey recommendations, and the postsurvey conferences may be summarized as follows:

The hospitals put into practice 35 percent of the hospital-items recommended in the area of policies and procedures, more frequently those pertaining to inpatient service than to outpatient service. They adopted 39 percent of the

hospital-items recommended in the area of personnel and 33 percent recommended for physical plant improvement. None of the recommendations for accreditation by the American Boards of Orthopedic Surgery and Pediatrics were fully implemented although several hospitals tried.

That this degree of implementation was achieved is gratifying, particularly so because of the apprehension some of the hospital staffs expressed initially about the project. This communitywide survey of the children's hospital orthopedic service was the first in the history of the health department's program. The hospitals may have been apprehensive about the possibility that the New York City Department of Health might withdraw approval, with resultant loss of prestige and funds for patient care and of patient referral.

It was the impression of the survey team, however, that many institutions were genuinely anxious to improve their services. By discussing recommendations frankly, bringing all the medical and nonmedical personnel concerned together, and acquainting them with the suc-

varied from the assignment of a pediatrician to the children's orthopedic clinic in 17 hospitals to the appointment of a qualified director of the anesthesia services in 4.

Where recommended, about 60 percent of the hospitals employed physical therapy staff and improved services for psychological testing of the children. About 50 percent improved the medical supervision of the hospital's department of physical medicine and rehabilitation and appointed a qualified director of the anesthesia service. About 40 percent appointed a qualified nurse in charge of the children's orthopedic service, provided 24-hour coverage of the service by a registered professional nurse, arranged for additional work experience in orthopedic nursing for the nursing staff, and employed an additional social worker for the children's orthopedic service. However, only one-fifth of the hospitals were able to develop a department of physical medicine and rehabilitation within the hospital or to assign a pediatrician to the children's orthopedic clinic.

Accreditation

Thirteen hospitals were counseled to seek accreditation by the American Board of Orthopedic Surgery or the American Board of Pediatrics or to seek a modified pediatric residency in affiliation with a hospital approved for this purpose within the community. None of these hospitals were able to fulfill any of these

recommendations, although 2 of the 6 hospitals tried to obtain approval for an orthopedic residency training program, and 1 hospital tried to obtain a pediatric resident on an affiliated basis (table 3).

No recommendations were made for residency approval in the specialty of physical medicine and rehabilitation because practically all of the hospitals with departments of physical medicine and rehabilitation are also approved for residency training in the specialty.

Physical Plant and Equipment

In 12 instances, improvements were recommended in the physical setup, divided equally between the inpatient and outpatient services (table 4). Three of the hospitals carried out the recommendation for the inpatient service and only one hospital for the outpatient service. In addition, during the survey period, two hospitals (one a large general hospital and the other a large specialty hospital) constructed entirely new buildings, and a third hospital (a large specialty hospital) undertook an extensive reconstruction program. In these three instances, the bureau staff participated in a review of proposed blueprints but could not be credited as being the instigating force for the change.

Illustrating the types of recommendations made for the inpatient service are: installation of running water in a large children's ward;

Table 2. Recommendations for personnel, 25 hospitals

Recommendation	Hospitals in which recommended		Hospitals applying recommendation	
	Number	Percent	Number	Percent
Assign pediatrician to children's orthopedic outpatient department.....	17	68	3	18
Provide 24-hour nursing coverage by registered nurses.....	16	64	7	41
Develop department of physical medicine and rehabilitation.....	10	40	2	20
Employ physical therapy staff.....	10	40	6	60
Appoint qualified charge nurse.....	9	36	4	44

Appoint qualified director of anesthesia service.....	4	16	2	50
Total hospital-items (250).....	95	38	37	39

Here too, much greater success was achieved in the inpatient than in the outpatient services.

That hospital consultation for orthopedically handicapped children is productive and has achieved some degree of accomplishment, even in its early phases, is clear. The greatest areas in need of further interpretation and strengthening include outpatient care, pediatric care,

development of departments of physical medicine and rehabilitation, and the team concept.

NRC Medical Research Fellowships

Applications for 1957-58 postdoctoral research fellowships in the medical sciences and radiology are being accepted by the National Research Council until December 1, 1956.

Awarded and administered by the Medical Fellowship Board and the Committee on Radiology of the Division of Medical Sciences, the fellowships include the following groups: national research fellowships in the medical sciences, supported since 1922 by the Rockefeller Foundation; the Donner fellowships for medical research, made possible by a new grant from the Donner Foundation; Markle fellowships in the medical sciences, provided through a new appropriation of the John and Mary R. Markle Foundation; and fellowships in radiological research, administered for the James Picker Foundation.

The first three of these programs offer research in the basic medical sciences for persons seeking careers in academic medicine and investigation. Fellows devote essentially full time to research at the fundamental level. Funds are not available to those wanting to get practical experience in clinical fields.

These awards, open to United States and Canadian citizens holding doctorates in medicine or philosophy or the equivalent, are not ordinarily granted to persons over 35 years of age.

Candidates for the radiological research fellowships must hold the degree of M.D., Ph.D., or Sc.D., or the equivalent. Preference is given to those whose training has been in the field of radiology, but persons from closely related disciplines are eligible to apply. There are no limitations as to citizenship, and the age limit is the same as in the other awards.

The fellowships are awarded in the early spring. Complete details and application blanks may be obtained from: The Division of Medical Sciences, Room 310, National Academy of Sciences-National Research Council, 2101 Constitution Avenue, NW., Washington 25, D. C.

cessful experiences of more efficient services, the team could help the chiefs of service and administrators plan and carry out important basic changes.

Intensive efforts of the survey team members, both as a group and individually, to interpret the purpose of the surveys dispelled some of the concern and apprehension, and the hospital staffs began to realize that the survey team's aim was constructive assistance. An important factor in success or failure of the survey technique and of hospital consultation in general is the interpersonal relationships established between the members of the hospital staffs and the members of the survey team. A friendly working relationship, professional respect, effective interpretation, sincerity, and technical knowledge are the essentials in determining success.

Frequently queried was the reason for the development of the hospital consultation program for handicapped children. The paying agency does have a responsibility in this field, both for helping to improve the care given the children and for guaranteeing to the taxpayer that the tax funds expended are being carefully and justifiably used.

The surveys disclosed several unexpected conditions: (a) An unevenness exists in the quality of care given the children by the group of hospitals; (b) children are being kept in the New York City hospitals longer than they need to be; and (c) more hospitals are approved for the care of orthopedically handicapped children in the New York City program than probably are needed.

Of these three findings, the hospital consultation program has been able to begin to cope with the first two, quality of care and overinstitutionalization. The excess of inpatient beds over the number of children requiring inpatient care is harder to solve. Most of these hospitals have been approved for participation in the orthopedic phase of the handicapped children's program for many years. Withdrawal of long-standing approval is usually difficult.

It is not surprising that more success was achieved in implementing the recommendations for the inpatient than for the outpatient services. In a large urban area the chief of the clinical service and his higher ranking staff usually do not participate personally in the realm of

outpatient care. This criticism of outpatient services is not only applicable to the institutions concerned, but it applies equally to the paying agency, which has supported inpatient care but has not yet accepted any financial responsibility for outpatient care. This is a curious policy since most orthopedically handicapped children in the lower income groups receive their medical care through the outpatient service, with only a small percent receiving inpatient care for briefer periods of time. Furthermore, the outpatient service has many roles to play in the care of orthopedically handicapped children—case finding, evaluation, and diagnosis; ongoing medical care and supervision; medical recommendations for special educational placement; and, theoretically at least, some responsibility for the care of the patient at home. Thus, if improvement in the care of orthopedically handicapped children is to progress significantly, outpatient care must be strengthened.

One of the expected findings was that hospital staffs are more immediately able to implement the simpler and more tangible recommendations, for example, improvement of patient records, than the broader and more complex recommendations such as the development of a team concept. While the term "team approach" has been used for many years, nevertheless, it is apparent that the concept has not yet been thoroughly understood in the care of the orthopedically handicapped child. Here, the value of a long-standing effective hospital consultation program can be truly demonstrated since continuing consultation and interpretation will be necessary to motivate the hospital staffs to develop their teams.

That no success was achieved immediately in the area of accreditation by the medical specialty boards is not surprising for several reasons: first, because it takes time for an institution to accomplish this objective, and, second, because there is the knotty problem of supply of approved residency training programs as opposed to the lesser demand for them quantitatively.

It was surprising that in such a brief period of time there was as much implementation of the recommended physical plant and personnel items, the two major areas in which the institution would have to spend the most funds.

acids have the ability to form soluble metal chelate compounds in which the polyvalent metal ion has been bound in a nonionic form. They are nonspecific; that is, they will inactivate practically any metallic ion with which they come in contact.

In a 1.0 percent solution, Versene Regular has a pH of 11.8. In order not to change materially the pH of the test waters, a 10^{-1} stock solution was prepared by combining 1 part Versene Regular with 8 parts double distilled water and 1 part 1N HCl. The pH of this solution was approximately 6.5. The neutralized EDTA 10^{-1} solution was sterilized by autoclaving for 15 minutes at 121°C .

The plating medium used was Bacto-tryptone glucose extract agar.

Escherichia coli ATCC 11229 was the inoculum used. All suspensions were prepared in buffered distilled water diluent (11) from cultures grown in nutrient broth for 24 hours at 37°C .

Effect of EDTA on *E. coli*

The first in the series of experiments was a study of the effect of the chelating agent on *E. coli*. For this study, varying log dilutions of EDTA in buffered distilled water were prepared. To each of these dilutions, tubed in 9.0-ml. aliquots, was added 1.0 ml. of a diluted cell suspension so that the test dilutions contained 200 to 300 cells per milliliter. These suspensions were kept at 25°C . for 2 hours and then plated to determine the viable cell count.

The light solid line in figure 1 shows the mean result of five trials. The 10^{-3} to 10^{-6} dilutions of EDTA gave a pronounced increase in recovery of cells over the recovery in cell suspensions containing no EDTA, that is, the buffered suspensions. This increase is indicative of an adverse effect of the buffer solution on *E. coli* under these conditions.

Chelation of Polyvalent Metals

The second in the series of experiments was a demonstration of the chelation of polyvalent metallic ions. Varying amounts of EDTA were combined with concentrations of metals known to be toxic to *E. coli* cells, and cells were then added to these chelated solutions.

Figure 1. Effect of EDTA on survival of *Escherichia coli* in several waters after 2 hours' exposure at 25°C .

Copper and zinc were the metals chosen for this demonstration. Stock solutions of 0.1 molar $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ and $\text{ZnSO}_4 \cdot 7\text{H}_2\text{O}$ were prepared using double distilled water. These were further diluted with sterile buffered distilled water so that the final concentrations were 0.25×10^{-5} molar for the copper solution and 1.0×10^{-4} molar for the zinc solution, which correspond to concentrations of 0.16 and 6.5 p.p.m., respectively. These solutions were tubed in 8.0-ml. aliquots. Log dilutions of EDTA from 10^{-1} to 10^{-7} were prepared separately, and 1.0-ml. portions were added serially to the copper and zinc solutions. *E. coli* cell suspensions were added to each of the copper and zinc solutions containing varying amounts of EDTA so that the final cell concentration was approximately 200 to 300 cells per milliliter. These suspensions were held at 25°C . for 2 hours and then assayed for viable cell count.

The dotted line in figure 1 shows the mean result of five trials with the copper solution. The optimum range for chelation of the copper

The addition of a chelating agent to water samples examined for pollution may be one answer to the problem of maintaining the coliform index near the level existing when a sample is taken. For periods up to 24 hours, a chelating agent materially reduced the "death rate" of coliform bacteria.

Chelation as a Method for Maintaining the Coliform Index in Water Samples

By E. L. SHIPE, Jr., M.S., and ADELAIDE FIELDS, B.S.

THE POSSIBLE USE of a chemical chelating agent to preserve coliform bacteria in water samples examined for pollution has been explored in a series of experiments by the Tennessee Department of Public Health. Samples of various waters, inoculated with *Escherichia coli*, were tested to determine the rate of decrease in viable cells and the effect of a chelating agent on this rate of decrease.

The coliform bacteria are widely used as indicators of pollution in untreated waters, although at present this practice is a matter of some controversy. Evidence that coliform organisms multiply in waters containing organic matter has been reported by a number of workers, including Caldwell and Parr (1), Leahy (2), and Mallmann (3). However, there appears to be more evidence that the coliform index decreases rapidly during storage of samples, even during storage at low temperatures. Caldwell and Parr (4), Cox and Claiborne

(5), the British Public Health Laboratory Service Water Subcommittee (6), and Leininger and McCleskey (7) have reported a material decrease of coliforms in samples after storage at various temperatures and for various periods of time.

These reports dealt primarily with temperature and time as factors influencing the decrease in coliforms. It seems reasonable, however, that the presence of certain chemicals in the water might also be a factor. The toxicity of polyvalent metallic ions for *E. coli* has been demonstrated by several workers, including Hotchkiss (8) and Fabian and Winslow (9). Waters receiving certain industrial wastes may well contain concentrations of metals sufficient to reduce the number of bacteria. A chelating agent added to samples taken from such waters would bind, or complex, any metallic ions present and would thereby prevent their deleterious effect on the bacteria.

Materials

The chelating agent used in the experiments was Versene Regular, the tetrasodium salt of ethylenediamine tetra acetic acid (EDTA). This compound is one of several powerful amino acids and their salts which are useful as complexing agents for metal ions (10). These

Mr. Shipe is associate director of the division of laboratories, Tennessee Department of Public Health. He is in charge of the section concerned with research and laboratory methodology. Miss Fields is principal bacteriologist of the division of laboratories.

Ten trials were performed for each water tested.

In figure 2 the loss of viable cells exposed to copper is shown by the heavy line. The circles indicate the viable cell count at the time of chelation with EDTA; the triangles, the count in the chelated suspension after a period of 2 hours' exposure; and the squares, the count after 24 hours' exposure.

In an unchelated sample, the cells in the suspension apparently die off shortly after 2 hours' exposure. In the 2-hour samples, the rate of cell count decrease was definitely changed by the addition of EDTA. As exposure to copper continued, the slope of the line increased from time of chelation to the 2-hour period. This indicates that as exposure continues progressive damage may be done to the cells which cannot be overcome by chelation. The slope from 2 hours to 24 hours was about the same for all of the time intervals.

Figure 3 shows similar data for the zinc solution. Chelation of zinc apparently holds the count at approximately the same level as it is at the time of chelation. From the 24-hour

Figure 4. Effect of EDTA on rate of decrease in *Escherichia coli* in buffered distilled water.

Figure 5. Effect of EDTA on rate of decrease in *Escherichia coli* in deionized distilled water.

samples, it can be surmised that some of the cells recover after standing in EDTA, or else the remaining cells are stimulated to multiply to a slight degree.

Figure 4 shows the results obtained when buffered distilled water was used as a suspending fluid. EDTA is apparently effective in reducing the rate of decrease in *E. coli* cells in buffered distilled water void of added metals.

In figure 5 are shown the data for the deionized water. This material had the lowest "bacterial death rate" of any of the waters tested. Even so, the addition of EDTA to deionized water resulted in an improved recovery, possibly because of an osmotic pressure difference more favorable to the cells than deionized water.

The mean pH of the waters tested was 6.87 ± 0.13 .

Discussion

These experiments have shown a rate of decrease in *E. coli* cells suspended in various waters. Waters containing small amounts of

solutions was 10^{-3} to 10^{-5} dilutions of EDTA. Above the 10^{-5} dilution there was a decided decline in recovery of viable cells because of insufficient EDTA and a resultant copper toxicity.

The mean result of five trials with the zinc solution is shown by the heavy solid line in figure 1. The optimum dilution of EDTA for chelation of zinc appears to be 10^{-3} . A gradual loss in cell recovery occurred as the dilution of EDTA increased.

Effect on Bacterial Death Rates

If fecal pollution enters water containing sufficient quantities of polyvalent metals to result in toxicity to the coliforms, samples collected from this water may well be free of coliforms by the time they reach the laboratory for analysis, even in a matter of a few hours. The addition of EDTA to such samples might interrupt this "death rate" at the time the sample is taken. To investigate this possibility, the following series of laboratory trials was made.

Cell suspensions of *E. coli* containing 2,000 to 3,000 cells per milliliter were prepared. Enough $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ solution was added to

Figure 2. Effect of EDTA on rate of decrease in *Escherichia coli* in 0.25×10^{-5} molar (0.16 p.p.m.) $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ buffered distilled water.

Figure 3. Effect of EDTA on rate of decrease in *Escherichia coli* in 1.0×10^{-4} molar (6.5 p.p.m.) $\text{ZnSO}_4 \cdot 7\text{H}_2\text{O}$ in buffered distilled water.

these suspensions to produce a 0.25×10^{-5} molar (0.16 p.p.m.) solution. Immediately after addition of the CuSO_4 , 10.0 ml. of the suspension was removed and placed in a tube containing 0.1 ml. of 10^{-1} dilution of EDTA. This tube was held at 25°C . for later analysis. After 10 minutes another 10 ml. was removed from the original suspension and added to a tube containing 0.1 ml. of the 10^{-1} dilution of EDTA. This was immediately assayed for viable cell count, and the remainder was held at 25°C . for subsequent analysis. Samples were taken at 20, 30, 60, and 120 minutes and treated as the sample taken at 10 minutes. All chelated samples were reassayed after 2 hours at 25°C . and again after 24 hours at the same temperature.

Similar trials were performed with a zinc solution, using 1.0×10^{-4} molar (6.5 p.p.m.) $\text{ZnSO}_4 \cdot 7\text{H}_2\text{O}$ as the final concentration of zinc.

Since buffered distilled water had shown an adverse effect over a 2-hour period, it was included in this study. Deionized (Crystalab Deeminizer) distilled water was also included. Samples of these waters were chelated at the various time intervals described.

Susceptibility of New Mexico Rodents to Experimental Plague

By R. HOLDENRIED, Ph.D., and S. F. QUAN, Ph.D.

DURING the last three decades, extensive studies have been made to elucidate the plague vector capacity of many flea species infesting wild rodents (1). On the other hand, there has been a lack of adequate investigation concerning the susceptibility to *Pasteurella pestis* infection of the wild rodent hosts of these fleas. Until both factors, vector potential and host susceptibility, are determined, the ecology of sylvatic plague will be difficult to understand. A flea whose natural host is refractory to the development of *P. pestis* bacteremia is unlikely to be a plague vector.

In the early laboratory studies of the susceptibility of wild rodents to *P. pestis*, McCoy (2, 3) and McCoy and Smith (4) established that several species of animals succumbed to experimental infection. Subsequently, other

rodents of these species were found in the field infected from natural sources. Although these investigators produced infection in seven species of rodents, the relative susceptibility of these animals to plague infection could not be evaluated from their data because the number of bacteria either injected or introduced by skin scarification was not recorded. But a rough comparison of species susceptibility was presented. For example, all 19 inoculated California ground squirrels (*Citellus beecheyi*) died of plague while only 8 of 15 inoculated valley pocket gophers (*Thomomys bottae*) died, an indication that of these 2 species the ground squirrel was more susceptible.

Later, from an extensive series of investigations on California ground squirrels, Meyer (5) concluded that young squirrels were more susceptible than adults; adult males were more susceptible than adult females; squirrels from a known plague focus were more resistant to infection than were squirrels from a plague-free area.

For detailed comparisons of the susceptibility of various animal species to plague, Meyer's work indicated the need for considering the plague history of the area supplying the experimental animals, as well as their age and sex.

With this background, the ecology of wild rodents and their ectoparasites was studied at the Santa Fe Field Station of the Communicable Disease Center, Public Health Service.

Dr. Holdenried, a senior scientist, and Dr. Quan, a medical bacteriologist, are with the Public Health Service's Communicable Disease Center, San Francisco Field Station in California. At present, Dr. Holdenried is detailed to the Dugway Proving Ground, Chemical Corps Research and Development Command, Dugway, Utah. During the time of this study, Dr. Holdenried was chief of the Santa Fe Field Station in New Mexico, and Dr. Quan was on temporary duty at the station. The New Mexico State Health Laboratory at Albuquerque provided use of its facilities and certain materials.

metals, 0.16 p.p.m. of copper or 6.5 p.p.m. of zinc, were the most deleterious tested. Even buffered distilled water was responsible for loss of approximately 99.7 percent of the cells within a 24-hour period. In deionized water 98.0 percent of the cells were gone within 24 hours.

EDTA in dilutions of 10^{-2} to 10^{-6} was found to be nontoxic for *E. coli* cells. Greater dilutions were of no value in maintaining cell viability.

The Public Health Service Drinking Water Standard sets 3.0 mg. per liter (3.0 p.p.m.) as the upper limit for copper and 15.0 mg. per liter (15 p.p.m.) as the upper limit for zinc (11). Both of these limits exceed the amounts of these metals used in our experiments. Copper and zinc in the quantities used were shown to increase materially the rate of cell count decrease of *E. coli* as compared with the rate for buffered or deionized distilled water. Addition of EDTA to samples of these waters, taken at various time intervals, resulted in a reduced rate of decrease in the cell count, the amount of reduction depending upon the time the sample was taken. For example, in a sample from water containing copper (0.16 p.p.m.) the percentage of survivors was reduced to 0.08 after 2 hours and to approximately zero shortly thereafter. The addition of EDTA at the time of sampling resulted in approximately 69.0 percent of the cells remaining viable after 2 hours and 40.0 percent after 24 hours. Similar increased recovery was shown for the other waters tested.

Several trials, not described in this report, have been run on samples of rural water supplies. In some samples, the addition of EDTA seemed to promote growth of the coliforms when the samples were stored at 25° C., whereas without EDTA, there was a decrease in numbers of cells during storage. This effect of EDTA, of course, has its disadvantages, in that it tends to give an overestimation of coliform density. On the other hand, would it not be better to find positive those water sources that previously have been reported negative because of a loss of viable cells from the time the sample was taken until it was tested in the laboratory than to report them as safe supplies? The addition of EDTA to samples might be of value in the isolation of enteric pathogens from

waters. Studies of this possibility are now being undertaken in this laboratory.

Summary and Conclusion

In laboratory experiments by the Tennessee Department of Public Health, the addition of the chelating agent ethylenediamine tetra acetic acid to samples of various waters (water containing copper or zinc, buffered distilled water, and deionized water) materially reduced the rate of decrease in *Escherichia coli* cells. It appears that, for periods up to 24 hours, chelating agents would be of value in maintaining the coliform index near the level existing at the time the sample is taken.

ification into mice. On death, the subinoculated mice were subjected to the same procedure followed for the test animals.

To investigate the possible development of latent infections, some of the animals that had survived at least 21 days after inoculation were sacrificed. Their spleen, liver, and, if present, enlarged lymph nodes, were pulped and inoculated into guinea pigs or mice.

Eleven rodents that survived previous inoculations were inoculated intraperitoneally with 0.5 ml. of plague toxins prepared according to the method used by Quan and associates (7) and Goodner and associates (8).

Results and Discussion

A total of 398 wild rodents of 21 species and 105 white control mice were inoculated with varying numbers of plague organisms. The wild rodent species ranged in susceptibility to infection from being as uniformly sensitive as the control mice to complete refractoriness. The LD_{50} for the laboratory mouse was about 7 bacilli.

The species found as homogeneously susceptible as the control strain of laboratory mouse were:

- Reithrodontomys megalotis aztecus* Allen, western harvest mouse
- Perognathus flavus flavus* Baird, silky pocket mouse
- Peromyscus leucopus tornillo* Mearns, white-footed mouse
- Peromyscus truei truei* (Shufeldt), piñon mouse
- Neotoma albigula albigula* Hartley, whitethroat woodrat
- Neotoma mexicana fallax* Merriam, Mexican woodrat
- Eutamias minimus operarius* Merriam, least chipmunk (probably as susceptible)

Although some individuals of the following species were resistant, the majority died of plague after infection with 1 to 1,000 mouse LD_{50} :

- Peromyscus maniculatus rufinus* (Merriam), deer mouse
- Peromyscus boylii rowleyi* (Allen), brush mouse
- Peromyscus nasutus nasutus* (Allen), rock mouse
- Neotoma micropus canescens* Allen, southern plains woodrat
- Eutamias quadrivittatus quadrivittatus* (Say), Colorado chipmunk

Those moderately resistant to infection (more than 1,000 mouse LD_{50}) were:

- Citellus variegatus grammurus* (Say), rock squirrel
- Citellus spilosoma marginatus* Bailey, spotted ground squirrel
- Microtus longicaudus mordax* (Merriam), longtail vole
- Onychomys leucogaster pallescens* Merriam, northern grasshopper mouse
- Thomomys bottae nervagus* Merriam, valley pocket gopher
- Thomomys talpoides fossor* Allen, northern pocket gopher

On the other hand, the following were refractory to intracutaneous inoculations of about a million mouse LD_{50} :

- Dipodomys spectabilis baileyi* Goldman, bannertail kangaroo rat
- Dipodomys ordii medius* Setzer, Ord kangaroo rat

The number of rodents in each species dying of plague after the experimental infection and the total number of rodents inoculated at each dilution are tabulated as fractions in tables 1 and 2.

Reithrodontomys megalotis aztecus and *Perognathus f. flavus* were more susceptible to experimental plague infection than were the white mice controls. The five species of *Peromyscus* were quite susceptible and succumbed to about the same number of organisms required to kill the controls, but certain individuals of both *P. maniculatus rufinus* and *P. n. nasutus* showed a fairly high degree of resistance. None of the three species of *Neotoma* survived inoculation of 10,000 organisms, but a few survived doses of less than 10 organisms. Reinoculated *Neotoma* survivors succumbed to 1,000 organisms. It was found that the diluted bacterial suspension initially inoculated into these animals was noninfectious. *Microtus*, *Citellus*, and *Eutamias* appeared to be more resistant than the *Neotoma*.

Thomomys and *Onychomys* showed a high degree of resistance, especially upon reinoculation. This may have been the result of an immunizing effect of the first inoculation. Two *Thomomys* that survived two previous intracutaneous inoculations succumbed to 100 million organisms inoculated intraperitoneally. Both species of *Dipodomys* were amazingly resistant

We present here the results of testing locally trapped adult rodents for susceptibility to experimental plague.

Procedure

Test animals were trapped between September 21 and December 17, 1953. After a liberal dusting with pyrethrum powder to kill their fleas, the rodents were held in the Santa Fe laboratory for testing between October 21 and December 18, 1953.

The inoculum was obtained from 24-hour cultures of *P. pestis*, Alexander strain, New Mexico (6), grown at approximately 28° C. in brain-heart infusion broth and in dilutions of the broth varying from 10⁻¹ to 10⁻⁸ in 1 percent peptone water. The number of viable organisms in an inoculum was calculated from the counts of the bacterial colonies, obtained by spreading on each of several blood-agar plates 0.2 ml. portions of 10⁻⁶ and 10⁻⁷ dilutions of the culture and allowing the bacteria on these agar plates to grow for 2 days in a 28° C. incubator. White laboratory mice, Princeton strain, inoculated with dilutions of the cultures, served as susceptible controls.

Each rodent in the experiments received initially 0.05 ml., inoculated intracutaneously into a shaven area over the right thigh. Intracutaneous inoculations were used on the assumption that they simulate infection by flea bites more closely than either subcutaneous or intraperitoneal inoculations. Some survivors of the initial injection were reinoculated intracutaneously 17 days after the first inoculation. A few survivors of the second injection were inoculated a third time. This was done intraperitoneally with 0.5 ml. of undiluted culture 41 days later.

On death, animals were autopsied. Evidence that plague was the cause of death was obtained from microscopic examination of stained smears of lymph nodes, spleen, liver, or heart blood exhibiting the typical bipolar bacillus; from appropriate macroscopic pathology; and from plague organisms identified on blood-agar culture of tissue smears. Tissues from test animals failing to show plague by one or more of these three processes were subinoculated by scar-

Areas in Santa Fe County, N. Mex., from which rodents were collected for susceptibility tests to experimental plague infection.

(table 2) are shown in table 3. The mortality index (10) is the ratio of the percent mortality to the average survival time in days and is identical to the mouse protective index as originally used by Meyer and Foster (11) to evaluate human serum with mice. The mortality index for the species of rodents that were homogeneously susceptible to infection varied directly with the dose of the infecting inoculant, whereas the index for the heterogeneously responding species (*P. maniculatus rufinus*) did not. The calculated range of the 95 percent fiducial probability is well within the observed results.

Three *P. maniculatus rufinus* yielded tissues infected with *P. pestis* 25 to 34 days after they received their last inoculation. These animals showed no obvious signs of illness prior to the

time they were sacrificed. The significance of the recovery of virulent *P. pestis* in tissues of apparently healthy mice, 5 weeks after inoculation, is not known. Obviously, the ultimate fate of the infecting organisms, had the mice continued to live, could not be determined. Of all the species tested, only *P. maniculatus rufinus* was found to harbor the organisms while remaining alive in apparent good health.

Olitzki (12) recently reported the isolation of plague bacilli from the spleen of *Microtus guentheri* and from the abscess at the inoculation site 6 weeks after the subcutaneous injection of 1 million bacteria. At the George Williams Hooper Foundation, University of California, Quan (unpublished data) recovered virulent *P. pestis* from apparently healthy

² Albino mice controls for all experiments.

to infection. None died upon intracutaneous inoculations of as many as 10 million organisms, but some succumbed to 100 million organisms inoculated intraperitoneally.

The number tested in each rodent species was insufficient to indicate possible variation in susceptibility between sexes and different ages. The lack of an opportunity to experiment at another time than the October-December period leaves unanswered the possibility that there may be a seasonal change in host receptiveness to infection.

Following the completion of the plague susceptibility experiments some of the surviving rodents were injected with plague toxins. Each of these animals received a toxic dose equivalent to 600 times the LD₅₀ for white laboratory mice. Each of two *Onychomys* receiving toxins died. The two *Thomomys*, one each of species *talpoides* and *bottae*, also succumbed. Three of the four *Dipodomys ordii medius* and one of three *Dipodomys spectabilis baileyi* were killed. All deaths occurred within 24 hours after the injection of poisons. The controls for each species survived for more than 3 weeks.

For four species of the rodents, the susceptibility to *P. pestis* of rodents from a plague-free area was compared with that of animals trapped in an area in which plague-positive rodents and fleas had been found (9). The map shows the proximity of the two areas. No difference was observed in the degree of susceptibility of the two sets of rodent species, *Neotoma a. albigula*, *Peromyscus t. truei*, *Peromyscus leucopus tornillo*, and *Peromyscus maniculatus rufinus* (table 2). These results contrast with the observations made by Meyer (5) on California ground squirrels. The reasons for these contrasting observations are not readily apparent. It is possible that the animals trapped in the plague-focus area were from populations without previous plague experience. Actual geographic limits of the plague focus could not be delineated, and no evidence could be found to substantiate an assumption that the infection spread throughout the trapping area. The difference between Meyer's observations and those in the present study may possibly be explained by the different species of hosts used.

The mortality indexes of four rodent species

General Hospital and Nursing Home Beds in Urban and Rural Areas

By JERRY SOLON, M.A., and ANNA MAE BANEY, B.A.

HOSPITAL and other medical facilities are distributed in particular patterns. Understanding the existing distribution patterns and the factors producing or accompanying them is an important step toward planning for facilities properly distributed to meet health needs.

This report analyzes the relative availability of general hospital and nursing home beds in terms of counties classified according to their urban or rural character. Within this framework it examines the distribution of beds in relation to per capita income, proportion of older people, and supply of medical personnel. This approach permits a more detailed examination of rural-urban differences than was possible through analysis of such differences based on general hospital service areas (1).

The study is based in part on data on general hospitals submitted for 1953 in State hospital plans for the Hospital Survey and Construction (Hill-Burton) Program. Information on skilled nursing homes was obtained in a 1954 national survey conducted by the Public Health Service. Detailed explanation of these and other data used in this report is given in Public Health Monograph No. 44.

Urban-Rural Classification

For the purpose of identifying the existing distribution patterns of beds in general hospitals and nursing homes, the county is a useful analytical unit, although it does not necessarily constitute a "trading area" in actual use of health facilities. However, ready statistical information pertaining to population and socioeconomic characteristics is available on a county basis. It is through correlation with such information that the distribution patterns of medical resources become understandable.

Public Health

MONOGRAPH

No. 44

The accompanying article supplements and reexamines, from another avenue of approach, the ground covered in Public Health Monograph No. 44, published concurrently with this issue of Public Health Reports. The monograph analyzes the availability of general hospital and nursing home beds in the framework of general hospital "service areas," which correspond to trading areas for hospital services. The authors are health program analysts with the Division of Hospital and Medical Facilities, Public Health Service.

Readers wishing the more extensive analysis may purchase copies of the monograph from the Superintendent of Documents, Government Printing Office, Washington 25, D. C. A limited number of free copies are available to official agencies and others directly concerned on specific request to the Public Inquiries Branch of the Public Health Service. Copies will be found also in the libraries of professional schools and of the major universities, and in selected public libraries.

guinea pigs killed more than 30 days after inoculation. Although recovery of virulent microorganisms from apparently healthy animals, 4 to 6 weeks after inoculation, may suggest how the plague bacillus could be maintained in wild rodents during interepizootic periods, this finding cannot be regarded as latent plague (13, 14) without proof that disease will finally occur (15).

Summary

A total of 398 wild rodents of 21 species were inoculated intracutaneously with 0.05 ml. of aqueous suspensions containing various numbers of *Pasteurella pestis* (Alexander strain, New Mexico) to test their susceptibility to plague infection in comparison with white laboratory mice inoculated identically.

The wild rodent species ranged in susceptibility from homogeneous sensitivity equal to that of the control mice to complete resistance.

The majority of the rodents that survived plague inoculation, regardless of species, died of toxemia after receiving about 650 LD₅₀ of plague toxins intraperitoneally.

The comparison of four species, *Neotoma albigula albigula*, *Peromyscus truei truei*, *Peromyscus leucopus tornillo*, and *Peromyscus maniculatus rufinus*, trapped in an area where plague was found with those collected from a plague-free area, demonstrated no differences in susceptibility to experimental *P. pestis* infection.

Since the available number of animals of any one species tested was small, such factors as sex and age could not be evaluated.

The possible effect of seasons on the susceptibility of the rodents was not investigated. The persistence of plague in the area where it occurred was not determined.

Figure 1. Ratio of general hospital beds to skilled nursing home beds, by urban-rural character of county, 1953-54.

The county classification system used here was first developed in the 1946 American Academy of Pediatrics study of child health services (2) and was brought up to date on the basis of 1950 data by Pennell and Altenderfer (3). In this classificatory scheme, size of population and nearness to densely populated areas determine the designation of each county as:

- Greater metropolitan.* Counties included in any one of 14 "standard metropolitan areas" of 1,000,000 population or more. A "standard metropolitan area" consists of a county, or group of adjoining counties, which forms an integrated economic and social unit around a central city or cities of 50,000 or more (4).
- Lesser metropolitan.* Counties included in "standard metropolitan areas" of less than 1,000,000 population.
- Adjacent.* Counties that touch a metropolitan county as defined above.
- Isolated semirural.* Any other county containing at least one incorporated place of 2,500 or more population.
- Isolated rural.* Counties having no incorporated community of 2,500 or more.

This urban-rural characterization of counties has an especially significant application to the manner in which medical facilities are distributed. The metropolitan and adjacent counties represent areas served by, or readily accessible to, medical facilities available in larger urban centers. The isolated counties, however, do not have easy accessibility to a metropolitan center and are therefore usually limited to the generally less comprehensive medical services which can be secured locally.

Table 1 shows the number of counties in each of the urban-rural categories and the corre-

sponding distribution of population. One-third of the counties in the United States, those identified as metropolitan and adjacent, with nearly three-fourths of the population, are accessible to the medical resources concentrated in large urban centers. The remaining two-thirds of the counties, designated as isolated, with about one-fourth of the population, are comparatively remote from the medical facilities of metropolitan centers.

Distribution of Beds

Metropolitan counties have the most general hospital beds, averaging over 4 per 1,000 population (table 2). Isolated rural counties have the fewest, with an average of less than 2 per 1,000 population.

Isolated semirural counties have relatively more general hospital beds (3.8 per 1,000 population) than do counties adjacent to metropolitan areas (2.8 per 1,000). Obviously, the location of a county adjacent to metropolitan medical services reduces the need for beds in the county proper.

Beds in skilled nursing homes show a somewhat different pattern of distribution (table 2). Metropolitan and adjacent counties have, proportionately, about equal numbers of nursing home beds (average of 1.3 to 1.4 per 1,000 population). The availability of nursing home beds diminishes as the counties become more rural (isolated semirural counties, 0.9 per 1,000 population, and isolated rural counties, 0.4 per 1,000).

Table 1. Distribution of counties and their population by urban-rural character of county, 1950

Character of county	Number of counties	Population	Percentage distribution	
			Counties	Population
All counties	3, 076	150, 697, 361	100. 0	100. 0

² Bed ratios for national and county-type totals are computed on estimated total number of beds (cf. table 2) rather than on actually reported beds as shown here.

County Characteristics

The availability of beds may be associated with certain measurable characteristics of counties other than their urban-rural character. Per capita income may be one such factor; its influence on the supply of general hospital beds has been demonstrated in earlier studies (2, 5). The proportion of the population aged 65 years and over may be influential, in view of generally greater use of both hospital and nursing home facilities by this age group. Another related factor may be the relative availability of medical personnel, including physicians and professional and practical nurses.

Per Capita Income

That the supply of beds in general hospitals and skilled nursing homes in counties tends to increase with per capita income is evident from table 4.

The volume of beds in nursing homes shows proportionately greater increases with increasing income levels than does the volume of beds in general hospitals. However, the individual counties do not adhere closely to the overall

tendency which shows nursing home beds increasing with income level. Rather, the pattern represents an average of county experiences which are widely dispersed about the general trend. The increase of general hospital beds with increase in per capita income, on the other hand, is more consistently displayed county by county. (The more consistent association of general hospital beds with per capita income is reflected in a correlation coefficient of .45, compared with a correlation coefficient of .27 for skilled nursing home beds—both significant at the 1-percent confidence level.)

Older Population

The proportion of the county population aged 65 years and over is as significant as per capita income in relation to nursing home beds (correlation coefficient of .28). The supply of general hospital beds, however, shows no relation to the number of older people in the area. As figure 2 indicates, this situation is found in both urban and rural counties.

The association of aged population with the availability of nursing home beds is independ-

Nationally, there is one skilled nursing home bed for every 3.3 general hospital beds. Figure 1 expresses the relationship between the availability of general hospital beds and skilled nursing home beds in the several types of counties. One skilled nursing home bed is available in metropolitan counties for every 3.0 general hospital beds; in adjacent counties, for every 2.2; and in isolated counties, for every 4.3 general hospital beds.

Areas surrounding metropolitan counties thus are comparatively favored in the location of nursing homes. They maintain proportionately as many nursing home beds as do the neighboring metropolitan counties, on an average, although their supply of general hospital beds is much below that of the metropolitan counties. This suggests a differential geographic pattern of development between general hospitals and nursing homes. The greater concentration of both hospitals and nursing homes in urban areas as opposed to rural areas may be explained in large part on the basis of economic factors. Nursing homes, in addition, have developed to a greater extent in urban areas as a consequence of the distinctive housing and family living arrangements characteristic of cities. They have, however, gravitated largely to the fringes of the cities, whereas hospitals have tended to be centrally located. Differential land values have been a strong factor in inducing nursing homes to locate away from expensive in-city sites, particularly in seeking larger tracts of land to provide some grounds

around the home. This phenomenon has probably come about through the conversion to nursing homes of certain types of residences typically found in more outlying residential areas. All of the patterning observed in the foregoing data represent central tendencies within a wide range of bed availability. In fact, among themselves, the counties of any one urban or rural type show a broad range of availability of beds.

Interrelationship in Availability of Beds

As we have noted in treating each of the types of counties as a whole, the distributions of beds in general hospitals and nursing homes are similar in some respects and dissimilar in others. Of further interest is the question of how the relative volumes of beds correspond within individual counties.

Table 3 presents the average availability levels of beds in skilled nursing homes for counties with different levels of supply of general hospital beds. Despite some tendency for levels of nursing home beds to increase with increasing supplies of general hospital beds, many departures from such a pattern occur. Furthermore, the counties represented within any one group by the given bed ratio are actually quite dispersed in their individual ratios. (The low degree of correspondence between the county supply levels of beds in general hospitals and nursing homes is reflected in a simple correlation coefficient of .09.)

Table 3. Relative availability of beds in skilled nursing homes, by level of availability of beds in general hospitals within each urban-rural county type, 1953-54

General hospital beds per 1,000 population in county	Average nursing home beds per 1,000 population					
	All counties	Greater metropolitan	Lesser metropolitan	Adjacent to metropolitan	Isolated semirural	Isolated rural
Total.....	1.2	1.3	1.4	1.3	0.9	0.4
None.....	0.8	2.2	1.0	0.9	0.6	0.5
Less than 1.0.....	.4	.6	.7	.8	.1	.1
1.0-1.9.....	.8	1.0	1.3	1.0	.5	.3
2.0-2.9.....	1.0	1.1	.9	1.2	.7	.5
3.0-3.9.....	1.2	1.3	1.2	1.4	.8	.3
4.0-4.9.....	1.4	1.4	1.5	1.7	.9	.3
5.0-5.9.....	1.1	.9	1.5	1.0	1.3	.1
6.0-6.9.....	1.3	1.6	1.4	1.3	1.1	.2
7.0 and over.....	1.4	1.5	1.5	1.4	1.1	.2

Correlation with
county bed-popu-
lation ratio for—

	General hospitals	Skilled nursing homes
Physician-population.....	.45	.25
Professional nurse-population.....	.55	.33
Practical nurse-population.....	.33	.22

Removing the influence of county per capita income does in fact reduce the extent of correlation between bed levels and the supply of professional nurses. However, a measure of association remains (partial correlations with general hospital and nursing home beds, respectively, of .39 and .21, compared with the

Figure 3. Average availability of general hospital and skilled nursing home beds among counties with different relative availability of medical personnel.

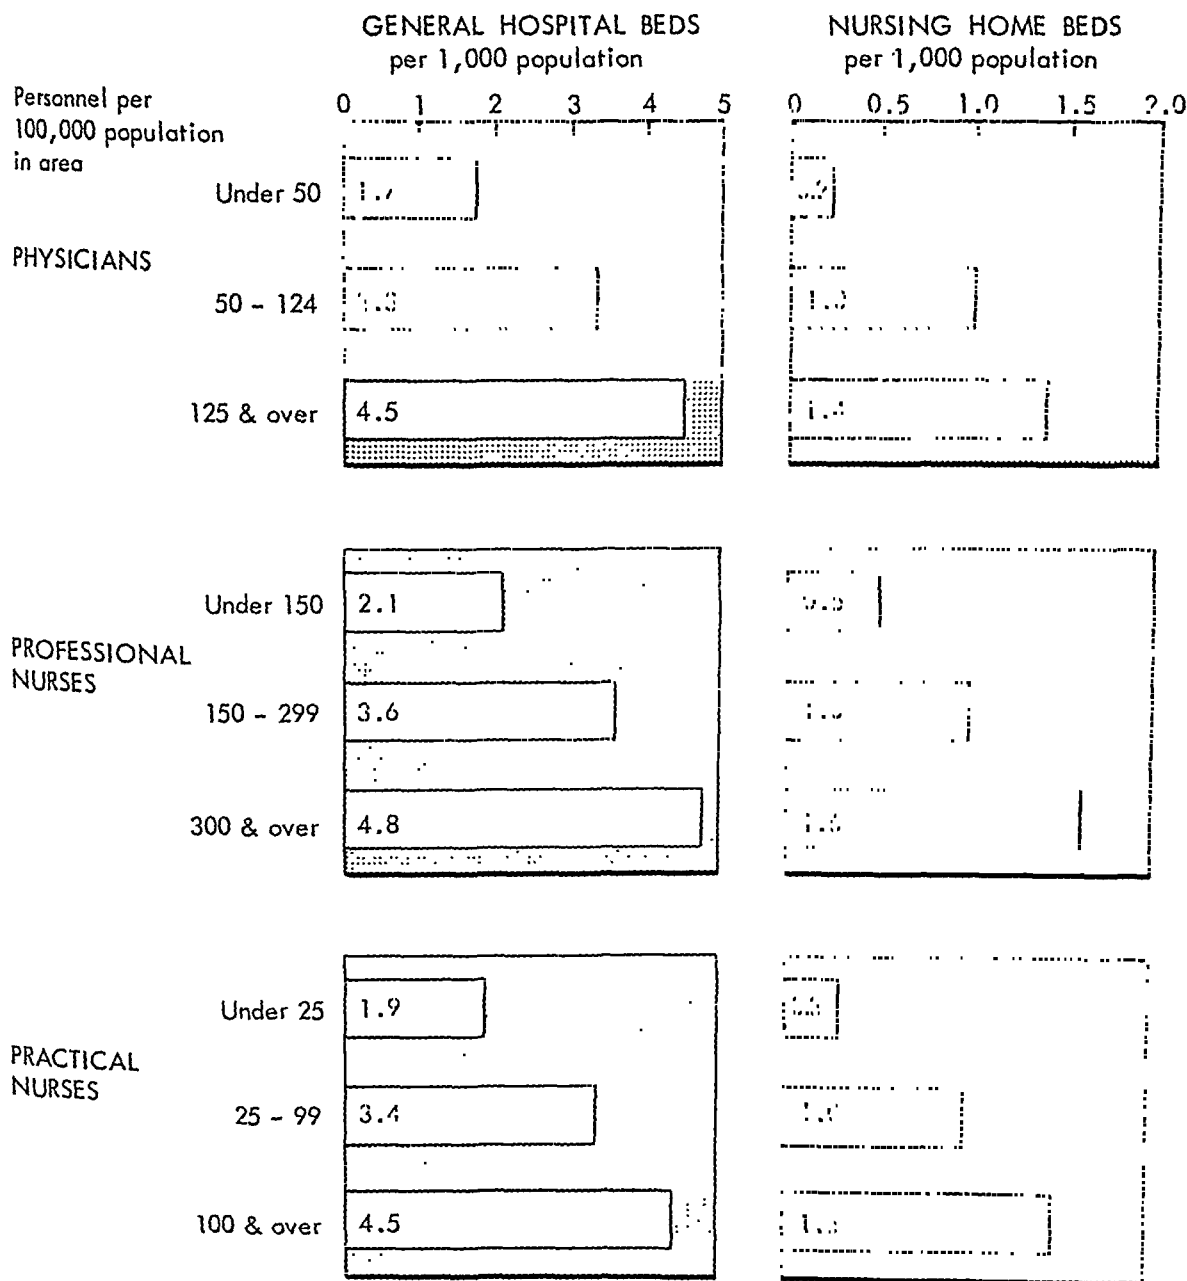

Figure 2. Average availability of general hospital and skilled nursing home beds among counties with different proportions of older people, by urban-rural county type.

ent of the influence of income level. The relationship with age is maintained even among areas of similar income. (Removing the effect of income, the partial correlation of nursing home beds with aged population is .26, similar to the simple correlation of .28 noted above.)

Medical Personnel

As figure 3 demonstrates, counties with relatively larger numbers of physicians and professional and practical nurses also have, on an average, more general hospital and nursing home beds. This holds true for the different types of urban and rural counties.

County per capita income probably has an

underlying influence here. There is a substantial association between county income levels and the supply of physicians and professional and practical nurses (the three types of medical personnel correlate, respectively, with county per capita income .58, .60, and .29).

To observe the effect of availability of medical personnel alone, with the effect of income removed, the category of professional nurses was examined in detail. This category, as just noted, correlates quite highly with per capita income. It also shows the highest correlation of the three types of medical personnel with the volume of general hospital and nursing home beds.

Conference Report

Administration building at the Public Health Service Hospital in Carville, La.

Progress and Potentials in Leprosy Research

A conference on leprosy research, the first sponsored by the Public Health Service's Interbureau Advisory Committee on Leprosy, was held at the Public Health Service Hospital, Carville, La., January 10-11, 1956. In a program planned by the Subcommittee on Leprosy Research, this conference brought together most of the persons in the United States currently studying the disease. Their discussions, which covered bacteriology, animal inoculation, immunology, biochemistry, pathology, metabolism and nutrition, chemotherapy, epidemiology, and clinical observations, are represented here by brief summaries of 25 of the papers.

simple correlations of .55 and .33—all statistically significant).

Composite Relationships

Per capita income and complement of professional nurses emerge from the foregoing analysis as rather significant factors associated with the volume of general hospital and nursing home beds in counties. The relative number of older people in an area is an additional important factor in the supply of nursing home beds.

The supply of professional nurses appears as the most effective correlate of availability of general hospital beds among the several factors studied. The nurse factor operates in the same direction as county income level, itself a major correlate, and further effectively incorporates the influence of income level. (Multiple correlation of general hospital beds with both these factors combined yields a coefficient of .57, no improvement over the simple correlation of .55 with supply of professional nurses by itself.)

In the case of nursing home beds, the combined effect of per capita income, proportion of older population, and professional nurse supply is greater than the effect of any one of these alone (multiple correlation of .42, as compared with simple correlations with these factors, respectively, of .27, .28, and .33). Here again, however, the influence of income is adequately reflected in the factor of professional nurse supply. Consequently, the combined effect of aged population and professional nurses yields as high a correlation (.42) with nursing home beds as the correlation with income level included.

Summary

Metropolitan counties, relative to other types of counties, are best supplied with both general hospital and nursing home beds. Isolated rural counties are the least supplied with both types of beds. The intermediate types of counties exhibit opposing patterns between general hospital and nursing home beds: General hospital beds are in rather low supply in those counties adjacent to metropolitan counties and in high supply in isolated semirural counties. Nursing home beds, in contrast, exist in relatively large

supply in counties adjacent to metropolitan counties and are in much lower supply in isolated semirural counties.

Little correspondence is found, county by county, between the number of general hospital beds and the number of nursing home beds. Although some average tendency is observed for the volume of nursing home beds to increase as general hospital beds increase, great variability among counties obscures the actual relationship.

The availability of beds is moderately correlated with certain socioeconomic factors. Per capita income and supply of medical personnel form a complex which is significantly related to the availability of general hospital beds. Correlating not as highly, but significantly, with these factors is the supply of nursing home beds. The proportion of county population aged 65 years and over apparently influences the supply of nursing home beds positively but reveals no measurable effect on the volume of general hospital beds.

Beyond the relationships examined in this study, there is much that is yet unexplained in the volume of beds established in different areas. For better understanding we must look to more subtle factors in the medical-sociocultural environment.

chain fatty acids. Intermediate types still metabolize the fatty acids, but not the succinates and usually not the acetates. Tubercle bacilli metabolize the fatty acids, but rather poorly. Johne's bacillus metabolizes only the short-chain fatty acids. Murine lepra bacilli metabolize none of these substances. This leads to the conclusion, said Gray, that they lie at the extreme pole of the sequence.

Studies of the behavior of various mycobacteria under varying oxygen tensions indicate that, whereas saprophytes may not grow in the absence of oxygen, they are not injured by the condition. However, anaerobic conditions are definitely injurious to lepra bacilli, suggesting a deficient or weak cytochrome system. Oxidative capacities of tubercle bacilli and murine lepra bacilli toward carbon dioxide are roughly equal; neither act on glycerine or glucose.

Tubercle bacilli are active in oxygen metabolism through the pyruvate sequence, but murine lepra bacilli are not. Johne's bacillus has been shown to require a "growth factor," especially for primary isolation. This is doubtful for tubercle bacilli and unknown for lepra bacilli.

Albumin and body fluids have a greater capacity to inhibit the metabolism of murine lepra bacilli than that of tubercle bacilli; for tubercle bacilli, the production of toxic lipids and the inhibition of succinates favor the bacillus vs. cell balance. The metabolic "capacities" of murine lepra bacilli appear to favor their infectiousness for animals.

Inducing Pathogenesis of *M. leprae* in Animals

WILLIAM H. FELDMAN, D.V.M., *professor of comparative pathology, Mayo Foundation, University of Minnesota Graduate School, Rochester, Minn.*

A method of inoculating animals with *Mycobacterium leprae* obviously would be of value as a means of enlarging understanding of leprosy. Yet, experiences with tuberculosis indicate that duplication of the human disease is not necessarily to be expected. For success, it would appear that the lepra bacillus must survive and reproduce intracellularly. The better known laboratory animals, as well as some others, have

proved refractory to infection, but many available species have not been tried.

The intradermal route of inoculation seems not to have been investigated adequately, Feldman suggested, especially from the standpoint of a medium of relatively low average temperature. There are at least two examples of animal mycobacterial diseases in which skin temperature appears to be a determining factor.

Possible procedures for reducing host resistance include whole-body radiation to reduce properdin levels and the use of hormonal substances or agents adversely affecting animal metabolism. The role of lipids in the lepromatous type of granuloma suggests a field for investigation. Adjuvant substances such as silica might be used in the inoculum.

Suggested animals are the anthropoid apes, hamsters, young swine and calves, and wild rodent species. Marsupials have not been studied adequately, although promising results have been obtained with them in related fields. Experiments of long duration should be planned.

The empirical approach to the problem of inoculating animals is necessary as long as nothing definite is known. To date, this approach has not been subjected to the applications of more than a fraction of the imaginative possibilities.

Comprehensive Program for Inoculation of Human Leprosy Into Laboratory Animals

CHAPMAN H. BINFORD, M.D., *chief, Laboratory for Leprosy Investigations, Armed Forces Institute of Pathology, Washington, D. C.*

Binford described the cooperative program of the Armed Forces Institute of Pathology and the Public Health Service Communicable Disease Center laboratories which is designed specifically for experimental inoculation of animals with human leprosy. The animals will be inoculated and kept in the CDC laboratories. The histological study of biopsy and autopsy specimens of the inoculated animals will be done at the Armed Forces Institute of Pathology.

Binford elaborated the numerous details which support the thesis that in man the lepra

Mycobacteria in Intracellular Environment

JOHN H. HANKS, Ph.D., *bacteriologist in charge, Leonard Wood Memorial Bacteriology Laboratory, Harvard Medical School, Boston, Mass.*

Metabolic methods of studying mycobacteria, with respect to their behavior during growth, embody two essential features which are quite different from the features of standard bacteriological methods. The first consists of a study of the hydrogen exchange as measured by the quantities of hydrogen liberated when oxygen is excluded from the reaction. Hanks discussed several methods of measuring hydrogen, by means of methylene blue or tetrazolium compounds. In combination with the tetrazolium compounds, the hydrogen produces a variety of colored substances. The second feature consists of study of the oxygen uptake by bacteria in the Warburg apparatus.

Studies by Hanks on the organism of rat leprosy have shown that the fresh suspensions failed to oxidize any one of a large number of test substrates. They have indicated that the substrate is not of particular significance in endogenous metabolism. When the basic substrate is given a yeast supplement, the metabolic effect is enhanced to some degree, but the enhancement is greater when an albumin-yeast complex is provided. Anaerobiasis greatly decreases the metabolic activity of the organism. This capacity of the organism to respire independently of the substrate clearly indicates that in the rat's tissues it is not dependent on cell respiration or intracellular enzyme systems. Although the organism may compete with the cell, it is able to respire or to metabolize independently from the cell.

Hanks discussed the substances present in plasma proteins, particularly with reference to factors that inhibit endogenous metabolic activity. These factors appear to be more effective in relation to the rat leprosy organism than to other mycobacteria. To illustrate, he presented diagrammatic sketches of the metabolism of the murine leprosy organism as affected by various inhibiting factors in plasma proteins. Until metabolic activity of the organism can be shown by metabolic study methods to

gain energy in time, there is no point in employing standard bacteriological methods in leprosy, he concluded.

Growth in HeLa Cells of Cultivable Mycobacteria

CHARLES C. SHEPARD, M.D., *Virus and Rickettsia Laboratory, Communicable Disease Center, Public Health Service, Montgomery, Ala.*

Shepard presented illustrations of his work on growth of tubercle bacilli in tissue cultures, using as his baseline H-37Rv human organisms as grown in the HeLa cell. Horse serum in the medium produces much better entry of organisms into the cell than does human serum. However, once bacilli are admitted to the cell, irrespective of the nature of the process, the organisms grow within the cell much better in the presence of human serum. Bacillary suspensions used were from those grown in Tween media, with their very small individual clumps.

Only doubtful growth can be visualized in 24 hours, but substantial growth is evident in 3 days and excellent growth in 5 days. At 7 days, under favorable conditions, growth begins to expand beyond the cell so that from this time onward intracellular growth is complicated by extracellular growth and by possible cell injury. Shepard showed sections and smears confirming the intracellular site of growth and illustrated the cords and perinuclear chains of growing organisms. He indicated an area near the centrosome of the cell as a particularly favorable site for growth.

Shepard concluded with a presentation of data indicating the usefulness of the tissue culture in the measurement of activity of drugs against mycobacteria.

Analysis of Properties of Mycobacteria by Metabolic Study

CLARKE T. GRAY, Ph.D., *biochemist, Leonard Wood Memorial Bacteriology Laboratory, Harvard Medical School, Boston, Mass.*

Saprophytic acid-fast bacteria metabolize succinates, acetates, and both long- and short-

been used in trying to identify the cultivated organism with that of the disease. Complement fixation tests, flocculation tests, and agglutination tests have been used for diagnostic or prognostic purposes.

The various serologic tests performed at Carville in the past 30 years were reviewed by Sister Hilary Ross. She described in detail the flocculation test devised by Olmos Castro and discussed its possible value as a routine laboratory method in the detection of overlooked cases of lepromatous leprosy in endemic areas. Also of possible value in leprosy is Middlebrook's hemagglutination test. A proposed study designed to detect specific antibodies in leprosy serum was outlined.

Induction of Reactivity to Lepromin by BCG Vaccine

JAMES A. DOULL, M.D., *medical director, Leonard Wood Memorial, Washington, D. C.*

In a carefully controlled study in the Philippines, Guinto, Doull, and Mabalay found that in 71.2 percent of previously negative children, the lepromin (Mitsuda) reaction had become positive 90 days after BCG vaccination. In control groups given saline or diphtheria toxoid, the proportion becoming lepromin positive was 27.1 percent, a finding that is attributed to natural (unknown) causes or the lepromin test itself, or to both.

By the device of leaving a sample of the originally selected children untested at the outset and unvaccinated, it was possible to compare the final lepromin status of three comparable groups: (1) children given BCG and an initial lepromin test, (2) children given saline or toxoid and an initial lepromin test, and (3) the basic controls. From comparisons of these groups, it was estimated that the proportion of all children who had become lepromin positive because of BCG was only 33.4 percent, because of the lepromin test, 7.2 percent, and because of natural causes, 11.5 percent.

Natural acquirement of reactivity is of great interest. It is too frequent to be accounted for by exposure to leprosy. It can hardly be caused by exposure to tuberculosis because only

2.3 percent of these children reacted to tuberculin (5 T.U. of PPD-S) at the outset as compared to 23.2 percent that showed reactivity of the Mitsuda type.

The Marianum Antigen in Leprosy

ROLLA R. WOLCOTT, M.D., *clinical director, Public Health Service Hospital, Carville, La.*

Wolcott presented three of a number of patients who were receiving monthly intradermal injections of a killed culture of a mycobacterium (called *Mycobacterium marianum*) isolated from a leprous nodule by Sister Marie Suzanne of Lyons, France. In all these patients, prolonged sulfone treatment had failed. Some local reactions to the antigen had occurred, indicating some type of activity on the part of the vaccine, but it was too early to say whether the vaccine was beneficial. No biopsies of the reactive lesions had as yet been made. The antigen was being used as a supplement to sulfone or other therapy.

Protein Patterns in Leprosy

RUDOLPH J. MUELLING, Jr., M.D., *associate pathologist, Charity Hospital, New Orleans, La.*

Chemical fractionation and paper electrophoresis studies by Muelling of serum protein in patients with leprosy gave the following results.

Active: 98 patients. The total globulin was usually elevated. The total protein level depended on the level of the serum albumin. The most common globulin aberration was a single clear elevation of the gamma globulin. A two-fraction elevation of the beta and gamma fractions came next, followed by a generalized increase in globulin with a predominant rise in gamma globulin. The lipoprotein was not remarkable. Fifty-five of the patients showed peaking elevation of the mucopolysaccharide. This fraction seems to be related to activity of the disease.

Amyloid: 15 patients. The total protein was elevated or not, depending on the level of albumin. As the albumin disappeared, there was an increasing curve reversal. There was more

bacillus has a natural preference for sites of lower body temperatures, and he expanded upon methods of applying this temperature selection to animal experimentation, using the most superficial inoculations practical and attempting to lower skin temperatures by frequent clipping of the fur of the animals. Mice of a hairless strain will also be used. Since in man the lepra bacillus has a predilection for peripheral nerves, intraneural inoculation will be tried.

For use in this animal inoculation program, human leprosy tissue frozen in solid carbon dioxide has been obtained from untreated patients in the Philippines and shipped by air to Washington. This was made possible by the cooperation of leprologists of the Philippine Government and the Leonard Wood Memorial and pathologists of the United States Air Force and United States Army in the Philippines and in Tokyo.

Possible Approaches to a Study of Antibody Responses in Leprosy

DONALD S. MARTIN, M.D., *chief, Bacteriology Section, Communicable Disease Center, Public Health Service, Chamblee, Ga.*

According to Martin, questions of serology in leprosy cannot be advanced far until bona fide cultures of the organism are available. In submitting a number of suggested procedures, he recommended study of the many variations in a few carefully selected patients. His discussion dealt primarily with possible applications in leprosy of the more recently developed serologic techniques, such as the Middlebrook-Dubos hemagglutination technique, which measures the specific anticarbohydrate titers. As in blastomycosis, there could be a relation in leprosy between protein antibodies and prognosis. Studies to separate the different protein and carbohydrate antigens and their antibodies could be approached, albeit only indirectly until cultures are available.

Methods of study potentially available include using precipitin bands in gels, tannic-acid-coated cells, and electrophoretic potentials of the reacting areas.

Possible Uses of the Properdin System in Studying Immunity and Bacteriology

JACK W. MILLAR, *Lt. Comdr., MC., USN, commanding officer, Naval Medical Research Unit No. 1, University of California, Berkeley, Calif.*

Approaches to the study of properdins in leprosy, both as they occur in the patient and as they might be activated or inactivated to alter infectivity of leprosy for animals, were discussed by Millar.

Briefly, properdin is a normal serum constituent, differing from antibody—a euglobulin activated by complement and magnesium. It kills or inactivates certain bacteria, lyses red cells, and combines chemically and reversibly with a yeast-carbohydrate complex (zymosan), from which compound it can be isolated. Properdin activity can be blocked temporarily in vivo by certain compounds, many of which occur in bacterial cell walls. Properdin is lowered by radiation.

Separation of Leprosy Organisms From Tissues

HOWARD J. HENDERSON, *research associate, Henry Phipps Institute, Philadelphia, Pa.*

Henderson proposes to separate the lepra protein antigens from suspensions of tissues rich in leprosy organisms, by homogenizing the tissue, overlaying the suspension with oil, and collecting the acid-fast material, by centrifuge, at the oil-water interface. Preliminary work was done by Henderson nearly two decades ago. He believes that, granting an adequate supply of material, this method will yield sufficiently concentrated bacilli to enable chemical studies of their protein moiety, lipoprotein moieties, and others. Various techniques have become available since his earlier studies.

Studies in Serology

SISTER HILARY ROSS, *biochemist, Public Health Service Hospital, Carville, La.*

Serologic studies in leprosy have had different objectives. Complement fixation tests have

that murine leprosy gives a spectrum closer to human leprosy than does murine tuberculosis.

Some variation in duration of experiments and drug withdrawals have been studied in relation to drug effectivities.

Epidemiology of Leprosy in Louisiana

L. F. BADGER, M.D., *chief, Leprosy Control Unit, Communicable Disease Center, Public Health Service, Atlanta, Ga.*

On the basis of an epidemiological study of leprosy, especially as seen in Louisiana, Badger stressed the following points:

1. The ideas that the disease is feebly contagious and that prolonged exposure is necessary are not supportable. The figures show that infections in children have been overemphasized; a good many occur after exposure in adult life. The sex incidence seems of relatively little or no significance.

2. The source of infection is more frequently outside the family than within.

3. Early recognition and early treatment are essential to control. Extensive case finding, in contrast to casual discovery of new cases, must be undertaken.

4. There is no basis for assuming that the disease could not appear and spread through other parts of the United States.

Leprosy Control in Louisiana

WILLIAM H. MEYER, M.D., *leprologist, Louisiana State Department of Health, New Orleans, La.*

Leprosy may have been introduced into Louisiana by slaves brought into the colony between 1719 and 1732. Or it may have been introduced from the earlier Spanish colonies in Mexico and elsewhere, as it is known that leprosy existed in those colonies in early days.

The first recorded control effort was the establishment by the Spanish governor Ulloa of an isolation area for persons with leprosy at Bolize in 1766. Historical records show also that from 1785 to 1807 there was a leprosy hospital near New Orleans, but from 1807 to 1880 nothing seems to have been done. In 1894 the State established a hospital for leprosy patients

and in 1921, gave it to the Federal Government.

Current control efforts include visits to the patient's home by the physician to obtain information concerning possible sources and new cases of the disease.

There has been a steady decrease in admissions from Louisiana to the leprosy hospital at Carville. An estimated one-third or more of the AWOL cases from Carville reside within the State.

The Risk of Contracting Leprosy in the Household

FRED C. KLUTH, M.D., *Leonard Wood Memorial associate epidemiologist, Texas State Department of Health, Corpus Christi-Nueces County Health Unit, Corpus Christi, Tex.*

Among 456 household contacts of lepromatous leprosy patients in Texas, 12 new cases of leprosy (2.7 percent) were discovered. Nine others were suspected but unproved; some of these were in older individuals and were possibly inactive. In 78 nonhousehold contacts, 2 cases were discovered. In 112 contacts with cases of tuberculoid leprosy, leprosy was suspected in 1 and definite in 1.

In agreement with Meyer, Kluth emphasized the need for quiet and unheralded operation of contact investigation, with minimization of the "official" character of home visits, even to the point of mild deception of the patient's neighbors.

The number of new cases of leprosy in Texas each year remains about stationary. In 1955, there were 24, all from the usual foci. The average age of onset is surprisingly high, over 30 years.

Clinical Evaluation Studies of Drugs

JAMES A. DOULL, M.D., *medical director, Leonard Wood Memorial, Washington, D. C.*

Clinical evaluation studies of drugs in leprosy have been conducted by the Leonard Wood Memorial during the past 4 years in widely separated institutions in Japan, South Africa, and the Philippines. Results from the different institutions are similar.

single-fraction elevation than double-fraction; if there was a general increase, it was overwhelming.

Tubercloid: 17 patients. The albumin was usually normal. The total protein varied between 7.3 and 10.4 grams percent. The beta globulin was usually increased over gamma globulin. Alpha elevation was rare. The mucopolysaccharide was usually not elevated (11 patients out of 17); when increased, the increase was usually the type produced by a general infection. The lipoprotein was usually increased, probably because of the beta globulin increase.

Inactive: 30 patients. Two out of the 30 had elevated mucopolysaccharides.

Muelling offered suggestions for further investigations, particularly of the idea that the mucopolysaccharide levels are related to activity of the disease. Dr. Catherine Goetz and Sister Hilary Ross participated in the studies.

Histopathology and Leprosy

GEORGE L. FITE, M.D., *Laboratory of Pathology and Histology, National Institute of Arthritis and Metabolic Diseases, Public Health Service, Bethesda, Md.*

Fite posed the question: How does the accumulated knowledge of anatomic leprosy suggest or indicate lines for further inquiry? He declared that any consideration of advanced leprosy anatomically is ridiculous, as compared with the need for knowledge of the early phases. Classifications of leprosy are of themselves worthless. They are of value only in indicating where to look for the factors that determine whether a patient, including the "no leprosy at all type," has this or that type of leprosy.

Although studies of terminal nerves and nerve endings in early leprosy might yield a clue to a finite mechanism, it would be the mechanism that was important, not the nerve-ending involvement of itself. Fite discussed the realms in which the determinant factors might lie, indicating that none of them involved a primary histological study.

The epidemiologist has learned that the study of the epidemiology of the lepromatous disease alone is almost valueless. The serologist might profit by the lesson: The place to search for

serum antibodies may not be the person with the disease, but the exposed individual without the disease.

Amyloidosis in Leprosy: Observations in Pathology

LAWRENCE L. SWAN, M.D., *Lafayette Medical Laboratory, Lafayette, La. (formerly, chief of pathology, Public Health Service Hospitals, New Orleans, and Carville, La.)*

In 50 consecutive autopsied cases of leprosy, amyloid disease was the definite cause of death in nearly 40 percent, and was present in more than 46 percent. Figures available indicate that amyloidosis is not as important in leprosy in other countries, but the subject is not well studied. The disease, which is associated with abnormalities in the serum globulin, is still difficult to identify during life.

At Carville, amyloidosis has occurred in cases without such complications as tuberculosis, throat complication, syphilis, or chronic ulcerations, showing that leprosy of itself is factorial.

Chemotherapy of Murine Leprosy

Y. T. CHANG, M. D., *Leonard Wood Memorial fellow in pharmacology, National Institute of Arthritis and Metabolic Diseases, Public Health Service.*

Chang presented a review of the work on chemotherapy in murine leprosy. Mice are used as the experimental animals, and measurement of intraperitoneal lesions following intraperitoneal injections is used as the criterion. Test experiments require 3 months. This test, according to Chang, is as sensitive as similar tests for in vivo activity against tuberculosis.

Thirteen compounds have been tested: streptomycin, chlortetracycline, oxytetracycline, chloramphenicol, erythromycin, nicotinamide, pyrazinamide, para-aminosalicylic acid, amithiozone, isoniazid, B-283, diphenylthioureas, and sulfones. Only five of these, streptomycin, nicotinamide, pyrazinamide, isoniazid, and diaminodiphenyl-sulfone, were found active. Recently, cycloserine has also proved effective. Comparison of the various effectivities indicates

FRANK E. LUNDIN, Jr., M.D., *Public Health Service Hospital, Carville, La.*

Lundin reported briefly on clinico-pathological examinations of electrolytes in leprosy, BSP tests, and cold precipitable lipoproteins. In determinations of magnesium, calcium, phosphorus, and potassium, many serums gave results below the control range. Sodium and chloride showed a few serums above the range for normals. In six of the BSP tests, there was abnormal positive retention for which there was no explanation. Five of 144 patients showed protein precipitates in serums refrigerated for 24 hours. The precipitates redissolved

on warming and were shown by electrophoresis studies to be lipoproteins.

Treatment of Ocular Complications

STEPHEN J. HERBERT, M.D., *Public Health Service Hospital, Carville, La.*

Eye complications in leprosy, in particular improvements in treatments of oculomotor nerve residuals and the problems of treatment of keratitis, lid reconstructions, and the like, were reviewed by Herbert. Misconception and mistreatment of the secondary glaucomas have followed acute attacks of iridocyclitis in leprosy in the past.

Grants-in-Aid for Training in Air Pollution Control

Grants-in-aid for graduate training in air pollution prevention and abatement are now available from the Public Health Service.

Designed to increase the number, competence, and knowledge of professional personnel engaged in community air pollution control work, the grants-in-aid will be awarded to three groups: State and local air pollution control agencies or other public agencies for training their personnel, educational institutions for assistance in developing and supporting new courses, and individuals for specialized training in air pollution.

In awarding the grants, the Public Health Service will consider such factors as severity of the air pollution problem, appropriateness of the proposed course, and qualifications of the prospective trainee. Grants to public agencies and individuals will cover tuition and fees, travel expenses, and subsistence allowances or stipends. Those to educational institutions may be used to pay all necessary expenses connected with a course, including salaries of instructors. Grants will be limited to 12-month periods, but in most instances they may be renewed for additional periods.

Those interested in training during the 1956-57 academic year should apply as soon as possible. For each academic year thereafter, applications should be submitted by April 1 of the preceding academic year. However, grants will be awarded as vacancies occur, and applications may be submitted at any time.

Additional information and application forms may be obtained from the regional offices of the Public Health Service or from the Chief, Division of General Health Services, Bureau of State Services, Public Health Service, Washington 25, D. C.

The first series, with 852 patients, proved too complicated to be completely satisfactory. Five drugs or drug combinations and one placebo were used. Diasone, diaminodiphenyl-sulfone, and streptomycin proved equally effective. There was no advantage in the combined drugs and no effective bacteriological improvement.

A second series of 499 patients gave equal results with diasone, isoniazid plus diasone, dihydrostreptomycin, isoniazid and streptohydrazid.

In a third series now in progress, BCG vaccination in combination with drug treatment is being studied.

Additional pilot studies in the Philippines are designed to examine isoniazid, thiosemicarbazone, pyrazinamide, cycloserine, and combinations of these. Thus far, none of the hepatitis and convulsive complications have been met.

The first series, according to Doull, provided the first statistical evidence of the value of the sulfones in treating leprosy. Such evidence is absent in many of the reports of drug treatments.

Seromycin Trials in Leprosy

FRANK E. LUNDIN, Jr., M.D., *Public Health Service Hospital, Carville, La.*

Lundin reported the results of experimental treatment of 10 patients with seromycin. The dosage was 250 mg. every 12 hours. Treatment in two patients was discontinued because of complications. Five patients received sulfones in addition to seromycin. No bacteriological improvement has been recorded. Although there was probably some improvement, it was no greater than might be recorded from sulfone treatment alone.

Hemoglobin Types in Leprosy

HORATIO C. WOOD IV, M.D., *Public Health Service Hospital, Carville, La.*

In studies at Carville on the distributions of various genetically determined types of hemo-

globin, no differences were observed between the leprosy patients and normal populations.

Orthopedic Procedures in Leprosy

DANIEL C. RIORDAN, M.D., *division of orthopedics, Tulane University School of Medicine, New Orleans, La.*

Orthopedic procedures used for the prevention and alleviation of deformities resulting from leprosy were described by Riordan. He mentioned in particular ulnar nerve transplantations from the superficial site to a deeper site, in order to prevent trauma to the nerve, and opening of the nerve sheath in older cases, which often gives immediate relief of nerve pain.

Other reconstructive procedures used are:

1. Shoe corrections, drop-foot braces, and splinting to prevent hand deformities.
2. Toe and metatarsal amputations, removal of ulcers plus underlying bones, joint fusions of hand joints plus bone shortenings, fixations in half-grasp positions in severe cases, and tendon transfers.

Limitations of Sulfone Therapy

ROLLA R. WOLCOTT, M.D., *clinical director, Public Health Service Hospital, Carville, La.*

Reviewing the story of the introduction and spread of sulfone treatment, Wolcott emphasized that the sulfones have their limitations. He concurred in Doull's remark that statistical studies clearly indicate the need for a more effective drug. According to a "probability of arrest" chart, a patient with lepromatous leprosy has a 40 percent chance of arrest of the disease after 8 years of steady sulfone treatment. This is not a good probability for an 8-year course of treatment. However, many other benefits accrue from the sulfones, especially in prevention of complications. Tracheotomies, once steadily performed, are not required; there is far less need for minor amputations, and almost certainly life expectancy is improved.

given way to the "nuclear" family of parents and minor children, who live apart from other kin and keep in touch largely through Christmas cards and occasional visits. As children mature, they leave the parental home to form separate nuclear families of their own, in a continual fragmenting process.

Today's family is mobile.

In this moving van era, a high proportion of families pick up and move to a new community, away from former friends and relatives, to take advantage of new job opportunities.

Dependent aged parents are now less likely to be supported by their grown children.

Rejection or isolation of the aged, linked in part to the modern family structure and functions (3), has contributed to a major health problem. Many of the ills of the aged (for example, much of the so-called senile dementia) flow not only from organic aging but also from roles of social isolation dictated by family, cultural, and economic rejection (4a). From a public health viewpoint, it is important to investigate the ways in which the changing family, among other forces in the social environment, has affected the aged.

The production of most goods and services has passed from the home to the factory and to service industries.

In 1949 for the first time the number of wives employed outside the home exceeded the number of employed single women. Women in the home perform fewer economic functions: They no longer preserve great quantities of food, make the family's clothing, or cultivate large gardens (5). The typical family of a century ago was rural and a major productive unit. Wives were valued in proportion to their economic contribution, which in large part determined the family's status. Children were valued as producers. The change in the family as an economic team, today less frequently operating a farm or family business, is widely believed to be a contributing factor to its shrinkage in size and its relative instability. For the most part, only outside wage earners now make a direct contribution to the family's income although wives and children still may perform economic services at home.

The family's formal control over the decisions of its members is much less than in past years.

The patriarchal figure, except in a few subcultures, has receded into myth; nowadays, grown children tend independently to choose careers, mates, and neighborhoods. Much of the family's former recreational, protective, and related functions have been transferred to community agencies, or they are purchased as services. Not all families and not all members of the family accept the changes equally or necessarily integrate them into their attitudes and emotions. Emotional conflict or deprivation often accompanies such a transformation, with implications for individual and public health.

The divorce rate, though down somewhat from its prewar peak, is relatively high as compared with levels of 1850 or 1900.

The future divorce rate will be affected by probable continuation of past changes in the family which have tended to weaken its stability (6a). Most of the evidence suggests that divorce is relatively more frequent in families with fewer children although we do not know to what extent children are a deterrent to divorce (7). (The past and present extent of desertions—the "poor man's divorce"—is unknown.) With the decline of the extended family and the anonymity of the urban family, particularly in a new community, there is less pressure by relatives and friends to keep the family together. The reduction of the family's economic functions diminishes the material dependence of the marriage partners on each other.

The Irreducible Functions

In view of the major changes and loss of functions, does the family still serve purposes of sufficient importance to assure its survival? The available data, fragmentary as they are, leave no doubt as to the affirmative answer. Marriage is more popular in the United States than ever: People now marry at a considerably younger age than, for example, in 1890; a much larger proportion of men and women are married today than two generations ago, and, though divorce rates are high, the remarriage rate is also high.

For the family to lose many of its traditional functions but still to become personally important to more people than ever before would

Public Health Begins in the Family

By HALBERT L. DUNN, M.D., and MORT GILBERT

THE FAMILY, as the most important institution in society (1), is intensively studied by sociologists and anthropologists. It is seldom studied by public health agencies, and it is almost entirely outside the current framework of vital and health statistics.

Births, deaths, diseases, marriages, and divorces are generally reported as events occurring to individuals. Our routine statistics tell us next to nothing about the family setting or family situation of these individuals or about the role of the family in health and disease. Although information of this type is admittedly difficult and perhaps impossible to derive from routine records, it is quite feasible to collect routine data on the "universe" of American families. The factual background would provide a base for specialized sample studies.

In this paper we will suggest, on the basis of existing statistical mechanisms, some of the ways in which public health agencies might proceed to collect usable data on families as well as on individuals. This of course raises a larger question, which we will attempt to explore first: What does the family have to do with public health?

Dr. Dunn is chief of the National Office of Vital Statistics, Public Health Service, and Mr. Gilbert is publications officer. Dr. Dunn presented a slightly longer version of their paper at the meeting of the Southern Branch of the American Public Health Association at Tulsa, Okla., April 4-6, 1956. Other reports on the family-centered approach to public health are presented on pp. 1011-1031.

With some 40 million families in this country—the number depends on how family is defined—most of us have firsthand knowledge of only a few. Nearly everybody defines the family differently and holds strong, individual opinions on its character. High divorce rates, dispersion and mobility of families, changes in moral codes and in occupation patterns, and, until the 1940's, falling birth rates had convinced many that the family as an institution was crumbling. The consensus of modern studies is that the family is going through a profound transition but that it shows no signs of leaving the social scene.

Over the Past Century

To gain perspective on the structure and functions of today's family, it may be helpful to compare it with the American family of a century ago. Ignoring cultural variations and concentrating on the typical American family, we have surveyed the extensive literature of family sociology, starting with Ogburn's classic analysis, "The Family and Its Functions" (2), and including many of the more recent works. Although interpretations and emphases are controversial because nearly all aspects of the family need more intensive research, most students of the family appear to agree that the following changes and effects between 1850 and 1950 have been significant.

The family has shrunk in size.

Today's typical family has fewer children and is limited to two generations, parents and minor children. What sociologists call the "extended family"—several generations living near together and bound by close ties—has

the place to catalog child ailments that have their principal genesis in family maladjustments. A vast literature of psychopathology deals with the pathetic results of parental overprotection or rejection; of prolonged mother-child separation; of hostile, overpunishing, or hypercritical parents; of abnormal sibling rivalry; of homes with continuous tension and discord; and sometimes of homes broken by divorce, desertion, or death. Public health is interested in the family if for no other reason than to investigate the etiology and prevention of a wide range of childhood ills.

Though the American family today is most likely to be small and urban, the dominant ideal still clings to rural ways and large kinship. The American family concept has never adjusted to the facts of city life. Many people have not yet learned to live in the modern family, and this lag has contributed to family ill health. In the small, isolated family unit, every relationship is intensified and more continuous (14). A child slighted by his mother cannot seek or expect comfort from his aunt if the aunt lives in another city. Bossard makes this point (15):

"It is the consensus that many Americans suffer from a sense of insecurity, and there can be little doubt that this is in part a heritage of the immediate family form. The very size of the family unit is important to the child in this respect for the same reason that the size of the ledge from which we view the precipice below affects our sense of security. The American child who lives and matures in a father-mother-child family unit stands on a very narrow family platform, even if it is in no way imperiled. To this is added the constant danger for the child that the few persons he must rely on may falter or fail."

Despite vast clinical experience with psychosomatic illness, despite millions of hours devoted to the recall of childhood traumas, there still is no agreement on the role of childhood experience in the development of health or sickness in adults. Many cases of the so-called "maladaptive reactions" of adults—the chronic fatigue or neurasthenic syndromes, the organ neuroses such as peptic ulcer and colitis, the disabling hysterias, the anxiety disorders, and the other psychophysiological ills—have been

traced (to the satisfaction of most psychiatrists and clinical psychologists) to inappropriate patterns learned too rigidly in childhood (16-18). Wartime evidence indicated that even the strong personality has a breaking point under sufficient traumatic stress; psychological disorder in adults does not necessarily stem from childhood maladjustment (19). Though the evidence is mixed, the family of childhood undoubtedly affects adaptations to stress in adult life. Whether we habitually react to stress or frustration by withdrawal, aggression, escape in fantasy or functional illness is often a reflection or continuation of fundamental patterns acquired in early life.

The Adult Personality

Emotional security in our culture is based mainly on assurances of affection and intimate companionship with other individuals. Human nature has a basic need for favorable emotional response from others (11b). No one outgrows it, and most suffer unhappiness and psychic, even physical, ills without it. This brings us to the other major function of the family: the stabilization of the adult personality.

The individual in an urbanized culture is often isolated and largely anonymous. He may be separated from kin and from most of his old, intimate friends. He makes new friends but in relatively formal relationships. Winch refers to the prevalent feeling of loneliness, to "the separation anxiety" that is apparently characteristic of today's society (20). For many individuals, the family has survived as the only remaining primary group, which Murphy defines as "the face-to-face world, the world of tenderness and immediacy, the world of security" (4c). Except for the family, our lives are now spent mostly in secondary groups—with associates on the job, in trade union or professional meetings, in fraternal or political organizations. We use these for many purposes, but they cannot meet our deep-seated need for love and emotional security. In this respect the family has become much more significant, and this is perhaps an important reason for its persistent strength.

Shurtleff has pointed to associations between marital status and mortality (21, 22). Taking

seem to present a paradox. Parsons and Bales (8a) in a recent study of family structure in the light of group interaction theory, resolve it this way:

"The family has become a *more specialized agency than before*, probably more specialized than it has been in any previously known society. This represents a decline of *certain* features which traditionally have been associated with families; but whether it represents a 'decline of the family' in a more general sense is another matter; we think not. . . . The family is not in any general sense less important, because the society is dependent *more* exclusively on it for the performance of *certain* of its vital functions."

These remaining vital functions include the rearing of children and the stabilization of the adult personality. Each is basic and irreducible, and in our culture it is difficult to imagine how they could be transferred to any other agency. Since the family is indispensable for bringing up the child and providing an emotional setting for most adult personalities, its optimum performance could avert many of the strains and maladjustments that now require pediatric, general medical, and psychiatric service.

The Rearing of Children

The newborn infant is without language, habits, customs, moral values, skills, or differentiated patterns of emotional expectation and response (9, 10). It is the family's function, particularly during infancy and the 6 early "golden years" of personality development, to transform the child into a social creature who is at home in the culture, and who carries and acts out the culture patterns without undue strain. The family has been variously called the cradle of the personality, the nursery of human nature, the porous buffer that lets the child meet experience as he can assimilate it, and that protects him from parts of the environment damaging to him if encountered too soon (4b).

It is in the family that the child acquires the basic patterns of living—everything from table manners to ethical values. He learns to look for certain types of emotional response from others,

to strive for various types of approved experience, to avoid experience that brings him pain and disapproval. Interacting with his family, learning how to win acceptance and avoid rejection in this small world, he forms behavior patterns, attitudes, and even deep-seated emotional reactions that will profoundly affect his character and personality throughout life.

The family experience begins to provide the child with a usable set of responses, attitudes, and habits that will later enable him to function as an independent adult in society. Without this foundation, human behavior would be totally unpredictable, and even an uncomplicated social structure would be unworkable (11a). But the family, in its infinite variety, does more than this. No child-rearing family is society in miniature, but a unique group that is easy to differentiate from any other group.

Children in a family setting acquire not only the generalized patterns of the culture but also a unique interpretation of the parents' subculture. Although all children of the same generation in a society develop much the same kind of human nature, each child is somewhat different from the products of other families. Thus the role of the family is not only to nurture a new generation that fits into the society but also to provide the great variety of personalities that society needs (8b).

Infants and small children in order to thrive apparently need personal, adult response over and above the satisfaction of hunger and other physiological needs. The high death rate that prevailed in even the most sanitary foundling institutions and the host of studies demonstrating damage in institutionalized children are often cited as evidence of the child's need for personal attention (12). This is a principal reason that foundlings and young orphans are placed in foster families as quickly as possible: Even a poor family generally does better by the child than a scientific regimen without personal interest.

But, as the psychologist John Dollard has remarked, "domestication" of the child "is without exception a process attended by conflict and strain" (13). Though the family is the best source of healthy, well-adjusted children, it is also the source of cases that crowd outpatient and child guidance clinics. This is not

medical practice has recovered much of its former prestige, and public health has broadened its interest to include the chronic diseases and their long-term effects on individuals.

But, despite progress, the family often remains in a medical vacuum, largely outside the scope of private medicine and nearly neglected by public health. We say "nearly" because one public health practitioner, the public health nurse, has always focused her attention on the family unit. It has been obvious to her, as to the family caseworker in social service agencies, that health or illness or recovery occurs in a family context.

The public health nurse always has taken stock of the unique family situation, of the family's income and education. Her methods have been mostly rule of thumb, based on the impressionistic data of her own experience. Lack of reliable baseline data on the family as a unit in health and disease has not prevented her from doing an effective job, just as the lack of mortality and morbidity data did not prevent effective work by the physician and the health officer 50 years ago.

But if the needed family data were available, the nurse and every other member of the health professions would learn to use the material, and come to rely on it as much as on our highly developed mortality data. None of us works in the dark by choice. Public health workers along with sociologists, demographers, family service workers, family counselors, child psychologists, psychiatric specialists, and business and market analysts would profit from real knowledge of the "universe" of American families: the norms and the ranges, the averages and the anomalies, and the interrelation of disease with varying families and family situations. Eventually public health, drawing on both the science of medicine and the methods of family casework, must develop an epidemiology of family disorders and diseases. Classical epidemiology knows how to deal with the spread of infectious disease in families, but for lack of technique and data it shies away from explaining why several members of a family develop the same gastrointestinal dysfunction or similar neurotic cardiac complaints. The wide spectrum of public health includes not only tuberculosis, poliomyelitis, and other infectious diseases that are routinely studied and attacked in

the family context but also many noninfectious ailments such as obesity, alcoholism, asthma, and essential hypertension, all of which are influenced usually by the family situation.

Although many types of illness have little or no connection with the family situation, "illness is one form of family maladjustment" (29a). This observation was made by Henry B. Richardson, a doctor of internal medicine who collaborated with associates in psychiatry, public health nursing, and social service, in a pioneering study of the family as the unit of illness. After several years spent in establishing the direct connection of disease with specific family situations, Richardson wrote (29b):

"The individual is a part of the family, in illness as well as in health . . . The idea of disease as an entity which is limited to one person . . . fades into the background, and disease becomes an integral part of the continuous process of living. The family is the unit of illness, because it is the unit of living."

Sources of Family Data

How do we begin to build up the family data that public health officials can apply?

An immediate, basic task of public health agencies is to improve the reporting of information contained on marriage and divorce certificates. Marriage and divorce are major punctuation marks in family history, as are birth and death. All these events change the characteristics of the population and of the family units within the population. They interrelate with a variety of other material from the decennial census and the current population surveys of the Bureau of the Census and from the special surveys of Federal and State agencies. This material as a whole makes up the benchmark statistics that describe the American family as an institution and as a process. Consumers of marriage and divorce statistics want facts on the formation of new families, on their growth and composition, and on their dissolution. Marriage and divorce statistics are part of family statistics.

The collection of marriage and divorce statistics is a function of the public health agency in most States and in the Federal Government. Generally, it is among the less emphasized functions.

the 1949-51 death rates of married men as equal to the index 100, Shurtleff found that the age-adjusted rate for single men was 163. For widowers it was 185, and for divorced men 207—more than twice as high as for married men. For women, the comparable index figures were: married women, 100; single women, 124; widows, 155; and divorcees, 155.

The figures themselves do not indicate whether marriage keeps people well or whether people who are well tend to marry and stay married. But various students of divorce, particularly the late sociologist Willard Waller, have likened the traumatic effects of separation to those of bereavement. They speak of the "terrific ego shock," the often "shattering" and "calamitous" effect of divorce on the personality, and point to the frequency of depression and occasionally suicide in the series of divorces that have been investigated (6b). Some recent studies suggest that the long-term personal disorganization that often followed divorce in the past is now on the decrease, perhaps because divorce has become socially more acceptable. But divorce, desertion, and bereavement are still major social forces with health aspects that deserve study and perhaps action programs.

The nature of marriage in our culture warrants study of its implications for public health. When the nuclear family is the only continuous intimate association, the partners expect more of each other in emotional response. This is one example of potential stress in an age of transition, characterized according to Kirkpatrick, "by confusion as to the family tradition." He continues: "Tangled ideologies produce family dramas for which the script and roles are not clearly defined. It is no wonder that family tragedies are enacted and that family members suffer confusion, anxiety, and unhappiness" (23a). Research studies of marital stress are inconclusive, but they indicate that a substantial proportion of husbands and wives are tense and unhappy in their marriage. Weiss and English, whose monumental survey of psychosomatic medicine includes a wide range of family-related illness, noted that "the advice to marry and have children has been a frequent prescription for certain ailments. But, paradoxical though it may seem, many illnesses

arise from the marriage situation, and this fact has not been so clearly appreciated" (24).

In two recent population studies in New York City and a rural part of New York State, and in a study of routine admissions to the surgical service of Cincinnati General Hospital, about half of the people examined in each sample showed moderate to severe neurosis (25). Many outpatient clinics and private physicians report that from half to three-quarters of their patients have symptoms primarily nonorganic in origin or have organic pathology which is aggravated by emotional disorder (26, 27).

These studies are cited not to suggest that any known proportion of this well of human misery originates in the family spring but rather to emphasize the need to explore the major human interrelationships that may bear on public health. One of these, though certainly not the only one, is the family situation. As Kirkpatrick says, "The family is the setting for the most intense emotional experiences which the individual has in the course of a lifetime. Birth, puberty, marriage, and death are family experiences. The family is the source of serene security, of anguished insecurity, of love and hate, of pride and shame, of ecstasy and anguish" (23b). It is small wonder that the family dramas and crises have a profound effect on the course of health and disease.

Illness and the Family Unit

Fifty years ago the family was the center of medical practice, as suggested in the old, revealing term, family practitioner. Before the era of specialization, the family doctor had a more intimate knowledge of all the family members, of their incomes and ambitions, of the subtle ways in which each reacted to the other. In treating each of his families, he could call on a store of firsthand social, economic, and cultural data, mostly unrecorded on the medical history, and apply this knowledge both to diagnosis and therapy. With the advance of medical science, the family doctor gave way to the specialist who rarely or never saw the patient in a family setting (28). Public health was devoted to preventing disease in the community at large, particularly through sanitary control of water, milk, and insects. In recent years, general

lating the events to the family might be introduced as record items? Would it be valuable to know in what kinds of families deaths from various causes are occurring? Do we want information about successive deaths in families and the composition of the family remnants? What could be done to improve fertility data and child statistics in general through a family-centered approach to the birth certificate? In all of this, the vital statistics system would need the thinking and consultation of health program people at the planning stage.

2. What types of special studies and surveys should be undertaken to enlarge our statistical knowledge of the family in health and disease and to enrich the developing core of vital and health statistics relating to the family? In addition to cross-section studies of family-centered records, we should investigate the feasibility of cohort studies for followup of marriage records and follow-back from divorce records. Moreover, a variety of surveys undertaken for health purposes could be made more valuable if family aspects were considered at the planning stage and incorporated in the study plan. The vital records, perhaps with additional items agreed to by the selected area, might serve as anchor points for such studies.

An urgent research problem is to learn how best to classify families, to determine by limited, short-term studies the kinds of information most essential for characterizing families. Such studies would provide the basis for the collection of family-characterizing data on a larger or a national scale. Without this basic knowledge of the "universe" of American families, the usual study of disease behavior in a selected sample of families cannot be generalized to any known population since there is no way to tell what part of the population the sample represents.

3. In addition to the decennial census, which has always been a rich source of data to students of the family, the current population surveys of the Bureau of the Census are open to special questions on marriage, divorce, and the family structure. They have been used several times for this purpose in the recent past. Questions relating health to the family situation in selected samples could be answered quickly and economically by this means.

4. Hospital and clinic records not only should include questions on the family medical history, as many do at present, but the records for all members of the family might be more accessible as a unit. Exploration of the objectives and technical problems might well be undertaken jointly by vital statistics people and medical record librarians.

5. Similar potentials exist in public health nursing records, which routinely contain data on the family, and which for special study purposes might profitably be collated with birth, death, and marriage records.

From a public health standpoint, the family is not just a social unit, it is an epidemiological unit. Study of the family requires an interdisciplinary approach of classical epidemiology and the social sciences. The statistical technique, for want of a short and simple term, might be called "social biostatistics," to which family-oriented vital statistics would contribute a share of the basic data.

A final quotation from Richardson is appropriate (29c):

"... we may now consider how to develop a science of the family. The language in which this science will be expressed will not have the precision of mathematical analysis, unless on a statistical basis. Much of the material, as in many of the natural sciences and in psychology, will remain on a descriptive level. Nevertheless we may hope to develop an understanding of the family unit, which will help us to predict the future course of events."

Although some health departments have worked vigorously to improve marriage and divorce reporting, the system on a nationwide basis is relatively primitive and compares unfavorably with that of most other countries of the western world.

No data at all are collected from a substantial number of registration areas in this country; marriage and divorce numbers and rates must therefore be estimated. One of the potential sources of error in these estimates is that in many areas marriage licenses are reported, but marriages are not; the proportion of unused licenses is a fluctuating variable. To take advantage of State differences in legal requirements for marriage and divorce, large numbers of people cross State lines; since reports do not distinguish between temporary and actual residence, the true marriage and divorce rates for any State's residents cannot be determined.

Because certificate information varies from State to State, national cross tabulations cover from 5 to 29 States, depending on the items included in the table. The number of States covered in tables of marriage and divorce characteristics varies not only from table to table but sometimes from year to year, making trend comparisons difficult and area comparisons all but impossible. This appraisal ignores the historical difficulties and the real progress that has been made (30, 31), but discussion of these points is outside the scope of this paper.

In thinking of the potential use of marriage and divorce data as components of family statistics, we should not confine ourselves to the existing fragments, which obviously can have only limited application at present, but instead we should think of what kinds of data might be acquired and applied.

The National Office of Vital Statistics and the American Association of Registration Executives have submitted a proposal to the Association of State and Territorial Health Officers for the establishment of a marriage registration area to be followed by the establishment of a divorce and annulment registration area.

The reasonable criteria for the admission of States to the marriage registration area which were developed by the Public Health Conference on Records and Statistics (32) will permit the inclusion of about 26 States at the outset.

The objective is the collection of a uniform body of data, consistent for all States in the initial area and eventually for the entire Nation, that will maximize the value of the statistics obtainable from items reported on marriage and divorce records.

But if all this were achieved, the present certificates alone could provide only a fraction of the family data needed. Although the present certificate data are indispensable as a base, there is much more information to be acquired.

How do we go about exploring the potentials in family statistics? The question has special application to the organizations directly concerned with vital and health records and statistics: the statistics section of the American Public Health Association, the American Association of Registration Executives, and the Public Health Conference on Records and Statistics. The initiative should come from vital statistics and records people because they are in the best position to know the possibilities and the limitations of vital records as a source of family data.

Each of us concerned with records on individuals should search for additional items for cross tabulation that would enable us to connect individuals as family members and to connect marriages, births, deaths, and divorces of these individuals as related events occurring in families with particular characteristics.

To serve the statistical needs of public health, it is time we broadened our concepts to include statistics on the family as a unit as well as on the individual. None of us at this stage can be expected to come up with immediate, definitive answers on the specific content of vital certificates, on appropriate technical methods and mechanisms, on the total scope of benchmark family statistics, or on any particular office's proper share of the collection of these data. It will take considerable work and discussion within our organizations to formulate even the first actual steps, but here are some specific lines that seem to be worth exploring.

1. From a family-oriented viewpoint, what can be done to improve the systematic data collection from birth, death, marriage, and divorce records? In reexamining the standard record forms, especially in connection with future revisions, what statistical elements re-

A FOCAL POINT IN HEALTH EDUCATION

THE FAMILY

Last April, the 16th Eastern States Health Education Conference at the New York Academy of Medicine dealt with the family as a "focal point in health education." But the main emphasis was on the family as a focal plane for health practice, as a basic ingredient of the social process. The program talks and lively discussions were sparked by questions and comments from the floor, as the audience discovered new resources and unsuspected peaks and valleys on what had been thought to be familiar terrain.

The full text of the papers offered is to be published by the academy, under editorship of Dr. Iago Galdston, secretary of the Committee on Medical Information. Dr. Galdston also is secretary to the conference committee, headed

by Dr. Herbert B. Wilcox, chairman. He will welcome inquiries or suggestions with respect to this conference or future ones. The address is 2 East 103d Street, New York, N. Y.

Public Health Reports is publishing briefs intended to touch upon a few of the salient issues suggested by the speakers. This treatment necessarily omits essential background discussion and illuminating details. The charts which appear in this conference report were among those given the delegates in the statistical survey prepared by Edward A. Lew.

A paper by Dunn and Gilbert discussing the need for improving family statistics for public health applications precedes this section (pp. 1002-1010).

of the family as a unit. And about the same time, family welfare agencies, once absorbed in relieving cold, hunger, and the need for clothes and shelter, began to broaden their services.

Dogmatic Opinion to Objectivity

During the early days, each piece of educational literature contained a heavy dose of moralizing based on Victorian ideals. Shortly after the end of World War I came the fault-finding and finger-shaking approach which tended to favor the child-centered home and to find fault with the parents. Articles in slick-paper magazines carried such titles as "1, 2, 3 for Better Parenthood" or "Temper Tantrums? You're at Fault!"

In recent years, research has produced a greater degree of objectivity, and it has challenged many of the earlier assertions. For example:

1. Three studies refute the notion that fathers are of diminishing functional importance in the personality development of American children.
2. Three studies fail to support the idea that interfaith marriages are less likely to be happy than marriages of those of the same faith.
3. Conflicting findings in dozens of investigations challenge the idea that personality development is adversely affected if a child is an only child.

Another trend apparent in the family life education movement is that from personal or neighborhood concern to professional concern supported by charitable foundations and universities and to public concern backed by Federal, State, and local funds. Interest was first exhibited by groups of parents who wanted to learn how to rear their children. Early support for research came from foundations and was carried out at universities. Family life courses were first introduced in colleges.

Opportunities Unlimited

Health agencies have countless opportunities to participate in the movement for generalized family life education. Many aspects of the prevention and control of disease and the promotion of health can be approached effectively through the family framework. Nutrition, for

example, is more than vitamins and proteins or calorie charts. It is the food customs of families that help give a larger purpose and meaning to mealtimes. Cancer is more than a question of early symptoms and the search for a cure. It is the adjustment of a family to a crisis, a test of its stability.

Changing Family Profile

The profile of the American family has changed markedly in the past 15 years.

More persons than ever before live in families. Americans are marrying earlier in life. The level of births continues to set new high records each year. And family size shows an upward trend.

Living in families are 94 percent of the population, with an average of $3\frac{1}{3}$ persons per household.

The number of families has increased 28 percent, from 32,166,000 in 1940 to 41,202,000 in 1954, or almost one-fourth more rapidly than the total population (table 1).

Husband-wife families have accounted for almost the entire increase. The number of married couples in 1954 exceeded 37,300,000. And all but about 1.5 million had their own households, reflecting a considerable decrease in doubled-up families prevalent during the war years.

It is significant that married couples represent 7 out of every 8 families with their own households. Of the other than husband-wife families, approximately 3 out of 4 are headed by a woman, denoting mainly that there are many more widows than widowers and that many husbands are serving in the armed forces or are away from home for other reasons.

The marriage rate, which spurted to an all-

By Edward A. Lew, actuary and statistician of the Metropolitan Life Insurance Co.

Evolution of the Character Of Family Life Education

In a book published in 1881, "Gems of Knowledge," Dr. Paul Barrington wrote that women have as much right as men to choose a life companion.

This—and other statements in a similar vein—contrasted sharply with the Victorian view of women as chattel and the family as an institution for the pleasure and comfort of men. A new point of view was emerging—a point of view that recognized the need for study of the family and its members and the values of education for personal and familial living. What has happened since Dr. Barrington's day may be traced in the accompanying list of significant events.

In the beginning, organized interest was centered on some particular member of the family or some special aspect of family living: children, mothers, or sex, for example. No thought was given to the family as a whole. During the 1920's and most of the 1930's, the focus was on children and how they could be taught habits and how best to discipline them. Family relationships were reduced virtually to a set of rules.

The 1920's saw the beginning of courses in family living in colleges, but what gave generalized family life education one of its biggest boosts was the change in the concept of education itself. High school was recognized as the privilege of everyone and therefore a key place for education for marriage and family life.

Originally, family life courses in high schools concentrated on generalizations about the family, but the youngsters were not content with this. They wanted their questions answered, questions about sibling rivalry (though they wouldn't use those words), petting, or going

steady. Thus, the discussion technique in family life courses evolved, and with it, the need for teachers trained in the subject.

Concurrently, parents, too, sought to find answers to family issues. General interest in the family court concept in the late 1930's showed that the legal profession was beginning to think

Significant Events

1877. Family service agency established in Buffalo in recognition of the need for casework services for the whole family.

1888. Child Study Association of America founded in New York by a group of parents who wanted information on how to bring up their children; Association for Child Study and Parent Education organized in Chicago by a group specifically interested in child psychology.

1896. National Congress of Parents and Teachers founded for the study of the child at home and at school.

1911. Family Welfare Association of America organized to bring together persons and agencies engaged in family casework.

1914. Family court established in Hamilton County, Ohio; American Social Hygiene Association founded to promote "those conditions of living, environment and personal conduct which best protect the family as a social institution," with emphasis on suppression of prostitution and reduction of venereal diseases.

1918. Federal funds made available to the States for venereal disease control and education.

1922. Federal funds made available to the States for maternal and child health programs.

1925. Marriage preparation and family living courses introduced at the University of North Carolina.

1938. National Council on Family Relations organized to provide a meeting ground for all who share in helping the family solve its problems.

1951. American Social Hygiene Association began expanded programs in education for family life; projects aimed at teacher preparation for family life education courses started soon thereafter.

By Wallace C. Fulton, M.P.H., public health associate, bureau of public health, medical department, Equitable Life Assurance Society, New York City.

20-24 are now married, or have been, compared with only 28 percent in 1940. At ages 25-29, the proportion now is 72 percent compared with 64 percent in 1940.

The median age of men at first marriage is only about 23 and that of women barely 20.

A study recently made by the National Office of Vital Statistics of the Public Health Service points out that 1 in 3 couples marry on a "shoe-string," with an income of less than \$60 a week.

Currently, about 11,800,000 married women, 29 percent of the total, are in the labor force. While it has long been customary for young wives to work until the baby came, recently more and more of them are returning to the labor market as the children grow up. Thus, about a third of all wives at ages 35-54 now work outside the home; for the younger women the proportion is about one-fourth. The fact that 2 out of 3 married women live in urban areas enables them to take advantage of employment opportunities.

The Baby Boom

Even more remarkable than the recent increase in the married population has been the continuing boom in babies. Since the close of World War II, births have averaged 3,800,000 annually, with each of the past 5 years suc-

cessively establishing new high records. Almost 4,100,000 babies were born in 1955, the equivalent of a rate of 24.9 per 1,000 population.

Accounting in part for the unprecedented number of babies born in recent years is an almost uninterrupted rise in fertility from its low level in the 1930's. In each of the postwar years, about 1 out of every 6 married women under age 45 bore a child, whereas in the mid-1930's the proportion was only 1 in 8.

The rate for first births began to climb immediately after 1933 and spurted sharply in 1941 and 1942. Demobilization brought an even greater jump in the birth rate of first babies in 1946 and 1947.

The upward trend in the birth rate of second and third babies since the beginning of World War II has raised such birth rates to considerably higher levels than those prevailing in the 1920's. Since about 1951 there has also been a definite rise in the birth rate of fourth and fifth children. This trend certainly presages a return to moderate-sized families, but it is not likely that families will become as large as those 50 years ago.

The high birth rates of the past decade are, of course, reflected in the proportion of families with dependent children, particularly among the younger married couples. A large proportion of families have a child within 5 years

Table 2. Percent ever married according to age, by sex, United States, 1890 to 1955

DEFINITIONS: *Family*—group of two or more persons related by blood, marriage, or adoption residing together. *Primary family*—embraces all the persons related to and including the head of the household. *Secondary family*—head of household is not related to the family sharing his dwelling, such as a group of roomers or resident employees. *Subfamily*—a married couple with or without children, or one parent with one or more children under 18 years, living in a household and related to, but not including, the head of the household or his wife.

time high of 16.2 per 1,000 population in 1946 upon demobilization, has since been declining. In 1955 the rate was 9.3 per 1,000. It is not expected that the number of marriages will vary greatly for several years to come. After the early 1960's, however, there should be a marked upsurge when the large number of babies born during the war and postwar years begin to reach marriageable age.

Early Marriages

The trend toward early marriage is equally marked for both men and women. In 1955 more than 14 percent of all girls at ages 14-19 had been married compared with only 10 percent in 1940. At ages 20-24 the corresponding proportions for women were 71 percent in 1955 and 53 percent in 1940 (table 2).

Slightly more than half of the men at ages

postponed to the older ages, it remains nevertheless an important social and economic problem. About 1 woman in every 2 who now becomes a widow before age 60 has 20 or more years of life ahead of her. Nine out of every ten widows live either in their own homes or with relatives. Of the remainder, about one-half live as lodgers or as resident employees; one-fourth live in hotels or similar places, and an equal number in homes for the aged or other institutions. Many widows past the prime of life are in the labor force.

Psychological Dynamics Of the Familial Organism

PHR A new prototype of the American family is emerging from the steadily changing patterns of family organization.

There is the changed position of women in society, their new role in industry, their achievement of equal rights with men, their sexual awakening and emancipation. Also there is the removal of the working father from the home,

By Nathan W. Ackerman, M.D., associate clinical professor of psychiatry, Columbia University.

the mother's expanded domination of home and children—the whole tradition of “momism.” With all this has come an inevitable shift in the relations of men and women, and in child-rearing attitudes. The homestead has been stripped of the traditional functions of work, religious worship, schooling of the children, and care of the sick and aged.

The values of self-selection of mate, of compatibility in marital relationships, and of child-centered family life are accentuated. But the increased freedom, while promoting greater creativeness, also induces confusion and turmoil in family roles. What a man expects of a wife and what a wife expects of a husband has become complicated by a multiplicity of needs, many of which are contradictory in nature.

Unit of Diagnosis—the Family

Many persons and many families feel insecure, confused, and isolated in their community position. They perceive these rapidly changing social patterns as menacing and as a withdrawal of support. Young parents, separating themselves from the older generation but failing to find a substitute in the wider community, feel alone and adrift. They undergo personal torment in searching out an appropriate path. Their torment intensifies the strain in family relations and imposes an additional burden on the family's inner life. The family then tries to compensate to an exaggerated degree for the individual's lack of security in the wider community by providing a protective barricade against what often seems to be a cold, harsh outside world.

The experience of the modern family underscores the fact that accurate psychiatric evaluation and effective treatment of individual patients is simply not possible unless the disturbances of these individuals are defined in the context of their emotional position in their family. The family is the unit of growth and experience, and therefore the unit of health and illness. There must be a shift of interest from the individual as the unit of diagnosis and therapy to the family group as the unit of diagnosis, therapy, and prevention.

Clinically, the first person to seek psychiatric help may prove to be either the most or the least

of marriage. The average number of children per family has also increased appreciably where fathers are under 35 years of age (table 3).

Children under 18 years of age now number nearly 57 million, an increase of 15 million in the 11 years since the end of World War II. This increase has broken all previous records and is greater, in fact, than the gain in the preceding half century.

The total number of children is expected to continue to climb, and by 1965 it is estimated that there may be upward of 65 million children

under 18 years in the United States. This would mean a somewhat larger average family than we have now.

Currently, close to 8 million children under 18, almost one-seventh of the total, live with only one parent or with neither, mainly because of family disruptions through death, divorce, or separation. Of these, almost three-fifths live with their mother, about one-tenth with their father, and the remainder under a variety of other arrangements, mainly other relatives.

The problem of orphanhood has been diminishing, but about 1 percent of the children under 5 years, 9 percent at ages 10-14, and 14 percent of those at ages 15-17 are orphaned.

Widowhood

Even though the number of widows in the population has been mounting rapidly, the proportion of women who are widows has been decreasing at every period of life. This is mainly the result of the decline in mortality.

Of the 7,600,000 widows, more than half are 65 years of age or older; two-fifths are in the age range 45-64, and less than one-tenth are under 45. Many of the widows in the younger age brackets have dependent children in their care (table 4).

Although widowhood has been increasingly

Births per 1,000 married women aged 15-44 years, by order of birth, United States, 1920-54.

The interrelations of individual behavior and family relationships need to be scrutinized in three dimensions: the group dynamics of the family; the dynamic processes of emotional integration of the individual into his family role; and the internal organization of individual personality and its historical development. The phenomena of family role constitute the bridge between the internal processes of personality and the group pattern of the family.

Purposes Served by Family

The family serves biological continuity by providing a socially supported group pattern for the sexual union of man and woman and a quality of parental partnership essential to the care of the young. The family is literally the cradle for the infant's tender mind as well as his body. Concretely the purposes served by the family are:

To provide food, shelter, and other material necessities which sustain life and protect it from external dangers; to form a matrix for the affectional bond of family relationships; to give opportunity to evolve a personal identity, tied to family identity, which supplies psychic integrity and strength for meeting new experiences; to set the pattern of sexual roles, preparing the way for sexual maturation and fulfillment; to establish social and ethical standards for social roles and acceptance of social responsibility; to cultivate learning and support individual creativity and initiative.

One important feature of family identity is its stability, its internal capacity for self-regulation and for restoration of a state of balance following an upset. There are at least two kinds of stability. One is characterized by resilience and capacity for accommodation to change and the other is marked by a rigidity toward change. In the meeting of new problems and crises, some families are weakened and others grow in solidity and emotional strength. Some families grow and learn from experience; others seem unable to do so because they are too inflexible and tend to disintegrate.

Families differ in their capacity to restore emotional balance. If this balance is not restored after disturbance, the inevitable consequence is a breakdown in emotional communica-

tion and empathy, increasing alienation in family ties, and confusion and impairment of family identity.

The interrelations of marital and parental identity and individual identity are delicately balanced. In a healthy family, out of the fusion comes a richer, stronger individual identity. The differentiation of the separate self is as important as is the basic family unity. The quality of difference in a family member need not be felt as a threat, any more than sex difference is a threat. Instead it should be welcomed as proof of the complementation of the self, the opportunity for new learning and greater fulfillment.

Mental health cannot be conceived in "all or none" terms. In emotional terms, people are neither wholly sick nor wholly well. Since mental health is largely a function of social processes, the more suitable test is the individual's integration into his group, rather than his personality structure defined in abstract terms. Surely mental health signifies the absence of mental illness, but it is much more than this. It implies confidence, courage in facing new experience, the capacity to grow, to learn, to live fully, to love and to share with others the adventure of life—in other words, a concern for the common good.

Family Health Maintenance

Social agencies have known for years that they must reach families before social and emotional disorders become fixed. The broken home, the vanished parent, the child in custody, all underline the fact that agency jobs are salvage jobs. Trends in medicine have coincided with trends in social welfare, and there has been a growing awareness of the interplay of social factors and

By George A. Silver, M.D., chief, division of social medicine, Montefiore Hospital, Bronx, N. Y.

sick member of the family. In evaluating the primary patient, it is important to trace the lines of significant involvement with other family members and to judge the illness as a reflection of the level of the family's emotional functioning. It is important, too, to discern in the arena of family life where lies the most critical focus of conflict and anxiety, to determine whether the core of the disturbance rests in the illness of one member or in the conflict of a particular family pair. Or does the conflict pervade all family relationships? In this sense, the behavior of one member may be interpreted as a symptomatic reflection of the emotional distortion of the entire family.

Basic Principles of Diagnosis

A system of family diagnosis calls for the evaluation of the group patterns of the family, the personality dispositions of each member, and methods of correlating individual experience and group interaction. Three empirically documented principles are relevant toward evolving such a system.

1. Abnormal behavior in adult persons is significantly rooted in the experience of childhood integration into a particular family, but continues to be molded by current family experience.

2. The diagnostic evaluation and therapy of emotional disturbance in a child, viewed as an individual apart from his family environment, is impossible. The proper unit for study and treatment is the child seen as part of the family, the family as part of the child.

3. Personality disorder and disturbances in social adaptation of adult persons may be better understood if examined not in isolation but as a dynamic changing pattern influenced continuously by the reciprocal effects of family interaction. Deviant behavior is thus seen not merely as a projection of fixed intrapersonality distortion but also as a functional expression of emotional interplay in significant personal relationships. The way in which the person perceives the image of others influences his image of self and vice versa. This two-way process continuously molds feeling, attitudes, and action.

Personality, born and bred in the social matrix of the family, and family and culture may be regarded as behavior systems existing at different levels of experience, each interdependent although interpenetrating parts of a whole which change and shift over time. Stability within the person and stability in the relations of persons and environment are mutually contingent, and the life and growth of the individual are inconceivable except within the group.

Number of widows in the United States, 1900–1953, and forecast for 1960.

Whether physical or emotional, preventive or therapeutic, individual conferences, group discussions, or consultations with parents about themselves or their children, action requires the resources of the entire team.

One important function of the health team is the service it can give in emotional upsets. However, a consulting psychiatrist orients and supervises the team members, inculcating psychiatric attitudes, information, and some techniques. He helps the team members to use the new skill to improve their own functioning and to add a new dimension of help to the patient.

The consulting psychiatrist does not actually perform services for patients. In weekly conferences with the team members he offers general information on psychodynamics, on patterns of behavior, and perhaps on a specific case or family. His social usefulness is enhanced many times by this means, and it may be that only through such organized service as a health team with a consultant psychiatrist will it be possible to bring the mental health approach into the medical care system.

Basic Hypotheses

Definitions of such terms as "health," "anxiety," "help," "guidance," and "support" were agreed upon early in the demonstration.

"Health" was defined as "harmonious functioning" in various facets of living. Emotional health is intimately tied to family relationships. Parents represent a profound influence in the health, or harmonious functioning, of the child and, consequently, of the adult since, as stated by Bowlby, "the form our family relationships take when we are grown up are, to a high degree, dependent on the form they took in our early years, and the very first relationship we make—that with our mothers—is the most important of all." The causes of failure in marriage often lie in family stress in the previous generation. Realization of this cyclical quality of emotional disturbance led us to concentrate health promotion efforts on providing parents with some knowledge and understanding of defects in their marital relationships, not to assess damages against them or their children.

In the early part of the study, more than half of the reports of doctors and social workers

noted "anxiety" among family members. The term needs clarification. Anxiety as a response is useful and necessary, provided it is not more than the stimulus warrants. Our concern is with types of anxiety in which the response is disproportionate to the stimulus and interferes with an individual's effective functioning in all areas of living.

This concern for emotional disturbances is within the family setting, and it is within the family setting that maximum effort should be concentrated. However, stresses such as low income, prejudice and segregation, and national and international political tension must also be weighed and considered in evaluating help for the family.

The demonstration is concerned with giving "help, guidance, and support" in physical as well as in emotional stability and growth. Injections and vaccinations are given against contagious disease. The public health nurse attempts to provide the latest information on nutrition, particularly to pregnant women. Poor or inadequate housing is dealt with as constructively as possible.

Health Education

A variety of personal and group educational approaches are used in maintaining family health. These include conferences, literature, informal discussions, and group discussions. Family conferences, in which parents meet the whole health team, are valuable. After the initial study and evaluation of each family are completed, a schedule or plan for health supervision is discussed in conference between the family and the health team. The knowledge that this group of professional people is concerned and interested and is offering suggestions is very gratifying to the family.

Although attendance at group meetings was not large, the health team was gratified to be able to reach even a small proportion of the study families. Some of the reasons suggested for the small attendance are competing entertainment and the accessibility and perhaps repetitiousness of educational forums in schools, churches, and neighborhoods. Ease of access to individual conferences also may militate against attendance at group discussions.

disease. Molding the environment, health promotion, and prevention of social illness must be combined with treatment of all disease.

The organization of medical care for the family must consider its needs, modern knowledge of prevention and treatment in both the physical and the socioemotional fields, and the cost—the cost of organizing health service and the cost of not organizing it.

A research demonstration in health promotion and preventive medicine is being conducted at Montefiore Hospital under the joint auspices of the hospital, the Columbia University College of Physicians and Surgeons, the Community Service Society, and the Milbank Memorial Fund.

Selected at random from the Montefiore medical group of the Health Insurance Plan of Greater New York are 150 families and an equal number of matched controls. Advantages and disadvantages of participation in the study were discussed frankly with all participants because, while it was important to get as many families as possible to cooperate, it was equally important that these families continue participation to the end of the program. The controls responded to a long and time-consuming questionnaire in approximately the same proportions as the study families participated in the demonstration.

Evaluation

The information collected from the families is to be used as baseline data. From this information an evaluation schedule is filled out and a numerical score is given to each individual in 11 different areas. At the end of the 4-year study period, similar information schedules will be completed and evaluation forms will be filled in. From these, the study families can be compared with themselves and with each other as well as with the control families, who will have a final evaluation of the same order.

No equally comprehensive initial evaluation was made of the control families. However, they have filled in a Cornell medical index and supplied housing and nutritional schedules. We have physical examination reports in their HIP charts, also.

The Health Team

In the demonstration, the health team is composed of a physician, a public health nurse, and a social worker. Medical care, preventive medicine, health education, health promotion and guidance, and psychiatric advice and some psychiatric help are the elements of the team's functions.

Medical consultants aid in diagnosis and treatment through the matrix of medical group practice. A social scientist consultant offers specialized skills in diagnostic and treatment methods appropriate to social factors, social disability, and social disorganization. A psychiatrist, a psychologist, and a health educator also serve as consultants.

The decline in numbers of general practitioners and the increased medical knowledge, diagnostic and therapeutic equipment, and skill have necessitated a medical adviser who is closer and more accessible to the family than the specialist. Fortunately, a link between doctor and patient is already in existence. Public health nursing and medical social work arose in response to such a need. With changing attitudes of physicians and loss of rapport between doctor and patient, public health nurses and social workers have been developing in skill and numbers. In the demonstration, the new, important aspect of their roles is prevention—to reach into families before disaster strikes.

The public health nurse herself shares in many areas of the doctor's role that deal with preventive medicine in the areas of nutrition and health teaching. In the area of interpersonal relationships, the social worker has become the professional practitioner, helping patients to understand their problems, providing access to other agencies and sources of care, and "shoring up" the emotionally sick and the socially disabled.

The health team can act as the family's guide and adviser because it has information, authority, and the confidence of the patient. Internally, the team must operate with mutual confidence. The Montefiore team has no captain; decisions reached in conference are referred to the person with competence in a given area or to the person with whom the patient has the closest relationship.

bers of the family, and his role in and relations with the community itself. The need of reducing the record to diagnostic and summary terms leads into the consideration of several general questions of instructional importance. One family's history illustrates two such questions: (a) the problem of selecting the initial steps and the frequently limited goals possible in aiding the restoration or promotion of family functioning and personal health and (b) the opportunity of examining the family for identification of diseases which have a familial risk.

The husband, an unskilled laborer, had been unemployed for a year. He had asthma and bronchitis, and official agencies were about to investigate the possibility that these conditions were sufficiently disabling to justify the transfer of financial support of the family from the category of home relief (for the fully employable) to that of aid to dependent children. He was found to be depressed, showed striking symptoms of self-devaluation, and his relations with his wife had deteriorated to the point of consideration of divorce.

Although the wife had not handled the family funds when the husband was the provider, she had since taken over the handling of public assistance funds. She seemed competent as a mother, but her ability as a wife was more open to question. Perhaps childhood illness and experiences, or the lack of much of a childhood—she had worked in a factory from age 8 to 18 years—may have qualified her ability to relate on a mature level.

A problem such as the unemployment of the head of the family offers a series of choices in the attempt at solution. Determined agency activity in finding the husband a job might restore his status again as the main provider and head of the household. Referral of the wife to a family agency for a fuller understanding of her situation and of her attitudes toward her husband and even of her version of his behavior might identify which adult member in the family is the better able to form a relationship. Or the husband might be referred to a psychiatrist for an examination to determine whether his behavior is evidence of a psychological disorder that may disqualify him for work or for certain kinds of work.

The nature of the training and experience of

health personnel may be the main determinants of the choice of one of these directions toward more healthful functioning. The physician, the social worker, and the public health nurse each select a different approach to this family's problem. Further, there are times when vocational advice may require inquiry into the health status of family members and understanding of family relationships.

Family Disease and Familial Risk

In the care of an individual or family a doctor's concern must include attention to resistance and susceptibility to disease. Ideally, in a full appraisal and in anticipating susceptibility to disease, inquiry needs to be extended to all relatives, living and dead, to pregnancies unfulfilled, and even to the yet unborn. Such a case study approach will provide students and teachers with data for a discussion of existing knowledge, or lack of knowledge, of the mechanisms of disease as influenced by genetics and by environment.

As a teaching device we may conceive "family disease" as multiple cases of a disease among relatives or single cases of disorders known to carry a "familial risk" to children. In the family mentioned previously there were two likely instances of disorders associated with familial risk to children. The mother had dextrocardia and 1 of the 5 children had epilepsy. Two maternal aunts and the maternal grandmother had gallstones, but it is not known whether the mother had gallstones as well. She had eclampsia on one occasion and her mother had hypertension. Little of significance can usually be drawn from the history of more distant relatives. On the subject of disorders known to be common, there were nutritional deficiencies, and these were presumed to be due to the family's marginal economic circumstances.

The term "familial risk" denotes an empirical observation without the usual assumption of genetic etiology. Families share common environments as well as common genes, and families in consecutive generations show some tendency to remain within the same cultural, religious, and economic groups. In the family studied, two possible familial risks were present, epilepsy and dextrocardia. Because the

The Physician And the Family

PHR The character of the professional relationships of a physician both with the families of his patients and with his associates in health education and family care will be affected directly by the kind of education he receives in medical school. Recently developed teaching projects designed to advance the practice of health education in family living are evidence of a trend toward educating the physician to understand the health of the patient in relation to the family environment.

The origins and reasons for this movement are complex; their contributors, both individual and organizational, are many. In the past quarter of a century, the Association of American Medical Colleges particularly has emphasized the importance of appraisal of social and environmental factors in clinical teaching. The 5-day teaching institute held in 1952 by the Conference of Professors of Preventive Medicine and the Association of American Medical Colleges at Colorado Springs, Colo., gave considerable impetus to the further expansion of comprehensive medical care teaching demonstrations, with emphasis on home and ambulant care.

Of interest is the extent to which departments of preventive medicine have a responsible role in this form of extramural teaching, the appearance of psychiatry in a consultative teaching function on behalf of other departments, and new administrative arrangements and purposes in the relations of clinical departments for the demonstration of medical care. The Cornell comprehensive care and teaching program and

Boston University's domiciliary medical care program are good examples of the latter.

The State University Project

As a learning device and as a form of service, the value of simultaneous appraisal of all members of a household has been demonstrated in the Family Health Study Program of the State University of New York College of Medicine at New York City. This family medical and social appraisal is the major project of a 1-month full-time clerkship in environmental medicine and community health carried on at the health department's Red Hook-Gowanus District Health Center in Brooklyn, N. Y. Each senior medical student is assigned a family chosen for the program by the health center's community nursing service and as much of the study as possible is conducted within the family home in a series of frequent visits.

Physicians, social workers, public health nurses, social scientists, and staff of community agencies serve as consultants to the student and evaluate his findings with him individually and in groups. The recommendations found most acceptable in the joint conferences are acted upon by the public health nurse in the further use of community agencies for continuing care.

The totality, size, and concentrated time span of the family studies of this program differ notably from what is usual in family medical practice where the physician's contact with a family is usually episodic and in response to a call for the care of the family member who is ill. In the State university study program all family members are equally the object of attention in the same time period. Some of the examinations performed go beyond those commonly made by a practicing physician; for example, after the student-family relationship has become stabilized, examination may be made of the home to discover hazards that might cause accidents.

The Student's Appraisal

In making his report, the student appraises each member of the family at three levels, according to the individual's personal health, the latter's role in and relations with other mem-

By Duncan W. Clark, M.D., professor and chairman, department of environmental medicine and community health, College of Medicine, State University of New York, New York, N. Y.

bers of the family, and his role in and relations with the community itself. The need of reducing the record to diagnostic and summary terms leads into the consideration of several general questions of instructional importance. One family's history illustrates two such questions: (a) the problem of selecting the initial steps and the frequently limited goals possible in aiding the restoration or promotion of family functioning and personal health and (b) the opportunity of examining the family for identification of diseases which have a familial risk.

The husband, an unskilled laborer, had been unemployed for a year. He had asthma and bronchitis, and official agencies were about to investigate the possibility that these conditions were sufficiently disabling to justify the transfer of financial support of the family from the category of home relief (for the fully employable) to that of aid to dependent children. He was found to be depressed, showed striking symptoms of self-devaluation, and his relations with his wife had deteriorated to the point of consideration of divorce.

Although the wife had not handled the family funds when the husband was the provider, she had since taken over the handling of public assistance funds. She seemed competent as a mother, but her ability as a wife was more open to question. Perhaps childhood illness and experiences, or the lack of much of a childhood—she had worked in a factory from age 8 to 18 years—may have qualified her ability to relate on a mature level.

A problem such as the unemployment of the head of the family offers a series of choices in the attempt at solution. Determined agency activity in finding the husband a job might restore his status again as the main provider and head of the household. Referral of the wife to a family agency for a fuller understanding of her situation and of her attitudes toward her husband and even of her version of his behavior might identify which adult member in the family is the better able to form a relationship. Or the husband might be referred to a psychiatrist for an examination to determine whether his behavior is evidence of a psychological disorder that may disqualify him for work or for certain kinds of work.

The nature of the training and experience of

health personnel may be the main determinants of the choice of one of these directions toward more healthful functioning. The physician, the social worker, and the public health nurse each select a different approach to this family's problem. Further, there are times when vocational advice may require inquiry into the health status of family members and understanding of family relationships.

Family Disease and Familial Risk

In the care of an individual or family a doctor's concern must include attention to resistance and susceptibility to disease. Ideally, in a full appraisal and in anticipating susceptibility to disease, inquiry needs to be extended to all relatives, living and dead, to pregnancies unfulfilled, and even to the yet unborn. Such a case study approach will provide students and teachers with data for a discussion of existing knowledge, or lack of knowledge, of the mechanisms of disease as influenced by genetics and by environment.

As a teaching device we may conceive "family disease" as multiple cases of a disease among relatives or single cases of disorders known to carry a "familial risk" to children. In the family mentioned previously there were two likely instances of disorders associated with familial risk to children. The mother had dextrocardia and 1 of the 5 children had epilepsy. Two maternal aunts and the maternal grandmother had gallstones, but it is not known whether the mother had gallstones as well. She had eclampsia on one occasion and her mother had hypertension. Little of significance can usually be drawn from the history of more distant relatives. On the subject of disorders known to be common, there were nutritional deficiencies, and these were presumed to be due to the family's marginal economic circumstances.

The term "familial risk" denotes an empirical observation without the usual assumption of genetic etiology. Families share common environments as well as common genes, and families in consecutive generations show some tendency to remain within the same cultural, religious, and economic groups. In the family studied, two possible familial risks were present, epilepsy and dextrocardia. Because the

parents in this family were cousins, the question was pertinent whether children as yet unborn to this marriage might be heir to dextrocardia. However, since as many as five children had been born without this rare congenital defect there is little probability of a later child having the condition.

Attitudes Affecting Counseling

The possible role of personal and professional attitudes in counseling may be illustrated in a study of a family of four. The father had advanced pulmonary tuberculosis, one child had recently recovered from chorea, and the other child had had rheumatic fever for 2 years and had been in a special institution for this disease. The mother had gone to work 6 months earlier, at the time of her husband's hospitalization. There had been no untoward consequences to the children with the mother at work, but the question was raised speculatively in conference whether she should have made this decision.

The 16 medical students unanimously agreed that the mother should have gone to work. But medical students believe in hard work, and they have a strong pragmatic streak. After all, they seemed to say, the woman had been working for 6 months with no serious consequences to herself or her children.

The intended implication of the question was what response representatives of special fields might make to the question of the advisability of the mother's employment, according to their professional knowledge and orientation. The following responses might have been made.

A pediatrician might be primarily concerned with the fact that two young, recently convalescent children were unattended on their return from school.

A psychiatrist might feel that the wife's pursuit of work, while relieving anxiety in her, could have an emasculating effect on the husband and could pressure him to a premature return to work.

An anthropologist might say that it is traditional for Puerto Rican women to work hard and that the mother's employment was a decision acceptable to both sexes of this ethnic group.

An internist might feel that prevention of

tuberculosis in the mother is the critical issue and that her undoubted recent exposure to the disease should weigh against her working, although his opinion might be based more on clinical prudence than on possession of the facts on the role of work.

Education for Parenthood

 Modern education for parenthood centers around the family rather than the mother and her infant. Today's classes for families expecting another child now include not only the father but the children, offer shared learning for the greatest sharing experiences in life, seek to expand the boundaries of family feeling, and foster an environment conducive to psychic growth for parents and children.

Apparently, the enthusiastic response to our classes at the Maternity Center in New York City and in other large centers of population coincides with a widespread desire for help. Our classes consistently attract more applicants than there are chairs available. Sometimes, young couples apply even before a child is expected.

In part, we attribute the favorable response to the fact that young couples wish to be equal to parenthood. They feel a need to develop their inner resources. They wish to learn what changes to expect in their relationship to each other and in their pattern of living.

Few youthful parents know what they should about human reproduction. Although the majority in our classes have attended college, they have little real knowledge of how a baby is born. Confronted with the process of birth, they wish to understand rather than wonder. Those able to assimilate medical knowledge seek the help of experts. But rather than imprecise answers,

By Hazel Corbin, R.N., general director, Maternity Center Association, New York City.

they seek facts from which to make their own decisions. They are not willing to accept a passive role. This attitude is perhaps more crystallized in maternity care than in other medical services.

Only 25 years ago, emotional security was a concept limited to psychiatrists and other professional workers. The parents of today, conscious of their own personality disturbances, try to create a good emotional climate for their children. They are irrevocably committed to the momentous adventure of parenthood, and they are unsure of their ability to live it well. They need not only to learn the elements of bathing and diapering an infant. They need help also in understanding their own and the baby's behavior. They wish to avoid the mistakes they feel their parents made unwittingly.

Unlike their parents, who often felt they had to possess a house and car before they could afford babies, today's young people base their security on the family and its social value rather than on material things. Whatever adds social value to the family strengthens their sense of security. Since formal education is an important symbol of ego value in our culture, the undervalued role of parent gains in prestige when it is approached by the educational route.

Individual Goals and Aspirations

Education for parenthood should help the mature individual to derive the utmost satisfaction from the experience and to share that satisfaction with others in the family. It should help the personality to mature in proportion to the complex responsibilities of parenthood. For the unborn child, it should prepare a suitable home.

Education for parents should emphasize the primacy of the home since the disruption of family life is at the root of much unhappiness. It should encourage a broad conception of the family unit to provide the child with opportunities for effective relationships and for learning to live with others. It should provide learning of permanent value so that parents continue to build for happy, healthful living long after they have forgotten the details learned in classes for parenthood.

To be effective, health education must be ac-

ceptable to people. It is important therefore to help the individuals in the group work out their own methods of achieving what they desire. Although a core of pertinent information should be given, it is not desirable to insist on a particular pattern of performance or care. Effective education keeps in mind that individuals and groups are unique in goals, aspirations, and working methods.

By keeping the class small and having it meet over a fairly long period of time, it is possible to practice permissiveness, both in the teaching pattern and in the conduct of discussion. Young people are accustomed to frank talk, with each other and their friends. They are most receptive when the classroom discussion is at this level of freedom. As they become acquainted, the discussion grows in freedom. This spontaneous talk provides the teacher with the key to unexpressed and unformulated feelings.

Today's parents want to know about fertility and infertility, the uses and dangers of anesthesia and analgesia, the pros and cons of natural childbirth and rooming-in, and the psychophysical rationale of breast feeding. Many want movies of an actual birth.

A good educational program gives them the best available information on which to base their choices. The nature of the child, even before birth, is emphasized throughout so that parents are prepared to receive a baby as an individual personality and not merely as their creature, however loved, to be reared in the pattern of their personalities and wishes.

Often parents are far ahead of professional workers in their ideas of what they should learn. In controversial areas, it is wise to explain the difficulties that may prevent full realization of their desires so that they may adjust sensibly when their efforts fall short of complete success.

Whether they like it or not, for example, most women are obliged to have their babies in hospitals. Whether they like it or not, they are usually separated from their husbands during labor and from their babies after birth. If they make a choice between hospital and home based on realistic information, they are usually able to try sensibly to gain the advantages of both and to adjust without trauma if they don't.

Sharing of Attitudes

Naturally, all of the initiative does not rest with the class. A good discussion leader creates interest in what should be learned and brings about coincidence of teaching and learning goals. In an early session on intrauterine development, for example, we explain the baby's dependence on the mother and her food intake for the baby's body-building needs. Then parents are ready to receive the session on nutrition with real interest in the child's welfare as well as their own.

In teaching nutrition, we explain how different food elements serve the body. We do not say "eat this or that" but help each mother and father achieve good nutrition within the framework of familiar food habits and tastes.

Even though deliberate attempts at psychotherapy should be avoided, there can be no doubt that the airing of hopes and fears is beneficial. Throughout pregnancy, for example, there is a shift of interest back and forth between the child and self. Expectant parents often feel guilty and abnormal when their beginning parental attitudes give way to self-concern. They do not always realize that parental feeling is a developing and not a full-born thing. As they understand that a measure of emotional conflict is universal, they grow in

self-confidence, and the motivation for learning is strengthened.

No large-scale, continued evaluation of parents' classes has been made, though empirically it seems certain that the shared experience has psychotherapeutic value. Mothers comment on the supportive value of what they learned in class. They write of the pleased surprise and appreciation of their physicians at their performance during labor. Nurses report that women who have had prenatal preparation have an easier delivery and react better psychologically. Mothers and mothers-in-law remark on the emotional growth observed in their sons and daughters.

Education for childbearing does not pretend to eradicate neurotic attitudes or deep-rooted personality traits. It does seek to minimize or prevent new traumatic experiences, to help develop insights conducive to a favorable environment for the coming child, and to aid in the reconstruction of the family in a society that in many of its values and practices tends to rupture family bonds. Education for parenthood which is focused on the family and its individual and collective needs, and which fosters a secure, happy family setting, contributes to the welfare of society as well as of individual mothers, fathers, and children.

Chances in 1,000 that a newborn child will be orphaned before attaining age 18: mortality experience of white population, United States, 1900-1902 and 1950.

Culture and Health Practice

PHR Health, once thought to be governed by the heavens, by implacable fates, or by simple principles of will or virtue, was late to be associated primarily with the elements of earth. And even the earthly view has been troubled by the complex interplay of man with environment and of the individual with society.

The concept that ills have a dominantly physical origin, based in microbes or toxins, was barely established before Claude Bernard, Walter B. Cannon, and Sigmund Freud demonstrated that man is a whole compound of related physical and psychological processes. Such men opened the door to the study of the role that human values, emotional attitudes, and habits play in health. Talcott Parsons searched for roots of psychological patterns and influences within human societies and their social processes. Kardiner spoke of social emotions patterned in social structure. Anthropologists investigated social patterns for clues to their origin.

A preoccupation with evolutionary theory in the 19th century favored the thought that men and their societies "progressed" biologically or culturally, with accompanying assumptions of superiority of advanced races or cultures over the "primitives." Assumptions of racial distinction were discredited by Boas, who linked mental processes firmly with culture and led to a searching analysis of cultural variations.

Since culture itself is a human agency or organization of instrumentalities for adjusting and adapting to nature, it bears upon the shaping of personality and health, both individual and public. Individual reactions are mediated by a whole system of values, attitudes, and behaviors, even with respect to heart disease, arteriosclerosis, or amebic invasion.

In 1940, Dr. Leona Baumgartner suggested

By Marvin K. Opler, Ph.D., department of psychiatry, Cornell University Medical College, and Payne Whitney Psychiatric Clinic, New York Hospital.

that an understanding of the culture of a community would improve the effectiveness of health programs. There are many studies to illustrate how this principle applies in practice. But the culture is complex, requiring insights and knowledge from many contributing disciplines.

The concept of the family as a unit of practice was appraised in 1945 in a report by Dr. H. B. Richardson. Concerted skills of general practitioner, psychiatrist, and nursing and social work personnel were applied for a period of 2 years. It was concluded that the family concept led to better diagnosis and treatment, less pressure on existing clinical facilities, and relatively rapid progress toward sound medical action.

The concept of health and how to obtain it varies with the group, generation, and social class. One may start with existing health practices and behavior, note their function, and their integration into the culture. Such knowledge may become a component of epidemiology and administrative technique for the health officer.

An Approach to the Study Of Family Mental Health

PHR In our clinical studies of patients suffering from neuroses and psychosomatic disorders, we have been impressed by the significance of periods of crisis which, in the early stages of an illness, seemed to have determined its direction. In other cases, a period of healthy emotional development appeared to change more or less abruptly to one of unhealthy development at the time of a crisis associated with an upheaval in the social milieu of the patient.

When Erich Lindemann and I joined forces at the Harvard School of Public Health in 1952,

By Gerald Caplan, M.D., D.P.M., associate professor of mental health, Harvard School of Public Health.

we began to develop a framework for communitywide preventive psychiatry based on such studies. Our plans aimed to extend mental health help to families at times of crisis by promoting collaboration between psychiatric workers and the caretaking agents of the community—clergymen, educators, nurses, physicians, and social workers.

Lindemann's investigations of the psychological reactions experienced by the survivors and close relatives of the victims of the Cocoanut Grove fire in Boston had convinced him that a mourning process is accompanied by characteristic emotional changes, that there is a well-defined psychological disturbance in direct reaction to a bereavement, and that an individual who does not succeed in handling the emotional problems involved will be likely to suffer from a consequent psychiatric illness. He also found that a physician, or better still, a clergyman could help a person successfully adapt to a bereavement situation and thus prevent the pathological sequelae of "unsuccessful grieving." His experiences in this venture led him to set up the Wellesley (Mass.) Human Relations Service, where community caretaking techniques are being developed to help individuals adapt in a mentally healthy way to a variety of hazardous life crises.

My findings from my studies in London and Jerusalem on the pathogenic effects of interruption or distortion of mother-child relationships in early childhood had aroused in me the hope that the introduction of mental health concepts into public health practice might improve the emotional environment of young children and lead to a communitywide reduction in the incidence of psychological disorder.

Such considerations have led us to a scientific study of certain common crises which we previously felt were the province of playwrights and novelists.

Our Formulations

Our conceptual scheme constantly emphasizes the interplay between the individual and the significant persons in his social milieu.

When we say that someone is mentally healthy or unhealthy, we are rating the equi-

librium of his functioning in relationship with others in his environment. We are rating his ability to initiate and maintain satisfying emotional relationships with others, to work productively and fulfill his inner resources, to perceive reality undistorted by fantasies, to adapt to his environment if adaptation is conducive to his welfare, and if it is not, to change his environment in a way that infringes minimally upon the rights of others.

The emotional equilibrium is kept stable by a complicated series of homeostatic mechanisms operating both within his personality and in the social system of his network of close interpersonal relationships. Changes in this equilibrium and in the person's state of mental health may occur during crisis periods.

The essence of a crisis is that a person cannot solve quickly a problem of basic importance by means of his normal range of commonly used problem-solving mechanisms but must employ novel patterns of solution.

Pregnancy, birth, death, and such important role transitions as starting school, a new job, or married life are examples of problems demanding novel solutions and involving the possibility of changes in the preexisting pattern of emotional equilibrium.

An alteration in relationships with those who satisfy emotional needs leads to frustration and eventual impairment of mental health.

In the disorganization precipitated by a crisis, old conflicts become symbolically linked with present problems. The pattern of their previous solution may influence the present adaptation.

A critical factor in determining adaptation to the changed situation is the support mobilized by the traditional helping practices of an individual's culture and by significant helping people in his environment. Help at this time produces long-lasting effects quite out of proportion to the effort expended.

The significant people in a person's environment whose behavior toward him is so important during a crisis are the members of his family, his close associates at work, leaders of the social and religious groups to which he belongs, and the caretaking agents of the community whose role is to help citizens in trouble.

Suggesting a number of avenues of explora-

tion, our formulations about large-scale preventive psychiatry should be tested by building up a body of knowledge concerning the range of adaptive and maladaptive problem-solving methods of individuals in regard to the more common crises, working out ways of integrating this knowledge within the professional framework of caretaking agents in the community, and developing an appropriate scheme for deploying the services of specialized psychiatric personnel in the most economical way to achieve community coverage.

Family Studies

To advance research on certain aspects of our program, we have established a mental health unit in a Boston health center and have built up a collaborative working relationship among psychiatric and public health personnel.

We chose the family unit for study so that we may understand how the family as a group augments or weakens the problem-solving capacities of its individual members.

We chose as our main categories of hazardous circumstances three events in family life with which health workers deal routinely: prematurity, congenital abnormality, and tuberculosis. These categories have the advantage of being notifiable conditions and thus being easy to sample from health department lists.

Our study is still in the pilot stage. So far we have gained entry into 50 families and completed an intensive study of 15. Our families range from middle middle class to the lowest socioeconomic class.

In each case, the public health nurses and physicians continue their traditional services and also help us collect data. As early as possible after the impact of the crisis, they introduce our worker to the family. His first task is to enlist the cooperation of each member in the study and to obtain permission to visit them in their home once a week during the period of the crisis.

After the crisis is over, we carry out an indefinite followup of the study families at progressively longer intervals in order to assess the immediate and long-term results on their mental health.

We have discovered that the discussion of

problems is welcome in middle-class families but is often viewed as dangerous by families of low status. Our general approach is to interfere as little as possible with the stressful situation and with the family's method of dealing with it, but after the crisis is over we take on a more therapeutic role in order to strengthen our relationship and obtain information about deeper aspects of the family interactions.

We have found that valid information about crisis reactions can be obtained only while the crisis is in progress. We postpone obtaining background information on the historical development of the family until the pressure of the crisis has passed.

In our studies we have found it profitable to refer to two patterns of family functioning which may be significantly related to eventual mental health changes. These are the "family life style," meaning the reasonably stable pattern of family organization which leads to a range of problem-solving possibilities from which the family, individually or collectively, may choose according to their perception of the demands of the situation, and the "intermediate problem-solving mechanisms," which introduce dynamic forms of adjustment to the crisis.

Although the life styles of certain families may be conducive to mental illness, in many others the life style affords greater or lesser opportunities for mental health. Whether mental illness or mental health develops will be determined by what choices are actually made during crisis periods. The current factors influencing the choices are therefore significant.

During the period when the new solutions are being worked out, certain patterns can be recognized in which the tension is reduced for the family as a group but at the emotional expense of one or more individual members. Emotional exploitation of a family member invests him with a role which infringes upon his needs. In such cases we have observed that the emotional problem was not being adequately dealt with by the group because of poor leadership, disorders of internal communication, or other organizational inefficiencies. Emotional exploitation of an individual reduced group tension by allowing abreaction of anxieties or ventilation of guilt in relation to an object acceptable to the family's value system.

We are beginning to tease out the factors which cause a family member to be singled out for exploitation in this manner as part of the family's response to a crisis, and which consequently endanger that person's future mental health by frustrating his basic emotional needs.

Social Work For the Family

PHR Not many years ago public health workers, physicians, and social workers learned about the family empirically without adequate theoretical formulations on which to base their practice. Today, there is an ever-expanding body of validated theory regarding the family to be tested in application.

Social workers see the family as the cornerstone of society and, therefore, the focus of their attention.

The bulk of present-day social work seeks to sustain families by providing food, clothing, and shelter. Only if such support seeks to enable the individual and the family to contribute in some measure to society is it compatible with the objectives of social work. It is vital for social agencies to be philosophically oriented and practically endowed to provide help that is not on a pennypinching, rockbottom basis.

Professional Cooperation

Characteristically, the social worker operates where there are symptoms of family or social dysfunction. The social worker may know that a patient is well enough to go home and that the hospital needs the bed immediately, but may

also know that the family is not in condition to receive the patient.

For example, a boy of 9, a victim of cerebral palsy, was admitted to an institution for handicapped children. Although he was living on an infantile level, he was found to have normal intelligence. During his 2 years at the institution, he learned to feed himself, to use the toilet, and to make his needs known verbally, although his speech improved but little.

The boy's discharge was recommended when it was apparent that he could be treated as an outpatient. However, his mother was not prepared for, in fact, refused to accept, the improvement in his condition. Consequently, the boy regressed at home and probably will require institutional care again.

Hospitals and social agencies must continue to work together in many ways to counteract situations in a family unit which may undo the work of the hospital and physician.

Group and Community Organization Methods

Social workers also use group work and community organization methods which strongly influence family health. The focus of such work is on larger social units, and provides recreational, creative, and citizenship outlets to promote the "pursuit of happiness."

Group interaction, peer relationships, and experience with authority and group leaders tend to produce changes in individual behavior which can be carried over from the immediate group, and the change is subsequently felt in family life.

I wish that public health workers had made more use of community organization skills during recent years in view of some of the roadblocks set up in segments of the community to the advances of medical knowledge. Their success in expediting therapy and release of tuberculosis patients, for example, had striking effects in the patients' families observed by social workers. There was an exacerbation of the anxieties and fears usually aroused by the return of a tuberculosis patient and an apparent prolongation of the period of readjustment.

The family accurately mirrors the community's stereotypes about the nature of contagion

By Virginia Bellsmith, M.S., professor of social work, New York School of Social Work, Columbia University, New York City.

reinfection, and disability in tuberculosis. Much more than the dissemination of educational material has to be provided if discharged patients are to be accepted by the community. Community social planning is needed. Unless community resources are realigned and augmented, patients can be isolated and house-bound.

The planned addition of social workers, with particular community organization skills, to the conventional health and welfare team might significantly alter community attitudes about tuberculosis and its victims and also modify community planning.

Similarly, the use of tranquilizers in mental illness and the mass application of poliomyelitis vaccines are other technological medical advances which require community cooperation for maximum acceptance.

Social Phenomenon

Although in the last 10 years, social workers have attempted to examine systematically con-

cepts and formulations of social work, none of the completed studies have given attention to a phenomenon which social workers have noted in their records for many years, that some adults who make mature, healthy familial and social adjustments grew up in families characterized by gross pathology.

The fact that such growth occurs is variously ascribed to innate strengths in the individual, to hidden assets which counterbalanced deprivation and distortion in the family, or to the fact that we do not yet know enough about the relative significance of traumatizing familial experience in children at different stages of development.

More study of family processes would certainly add to our understanding of cause and effect in personality development. But an examination of the histories of such adults leads me to the belief that a systematic exploration of the importance of consistency and continuity of pattern in such families may provide new understanding about the basis on which healthy personalities and strong egos are built.

PHS Staff Announcements

Dr. Robert J. Anderson has been named chief of the Public Health Service's Communicable Disease Center, in Atlanta. He replaces Dr. Theodore J. Bauer, who has been appointed deputy chief of the Bureau of State Services in the Washington headquarters.

As assistant chief of the Division of Special Health Services in Washington for the past 2 years, Dr. Anderson has directed operational research in tuberculosis, chronic diseases, venereal disease, occupational health, and heart disease control activities.

Following his first service assignment in 1940 as health officer in Newton and Texas Counties, Mo., he entered tuberculosis control work and served in Philadelphia and San Antonio as tuberculosis control officer and later with the California State Health Department. He became chief of the Tuberculosis Control Division of the Service in Washington in 1948.

Dr. A. L. Chapman has been appointed chief of the Division of Special Health Services, replacing Dr. Seward E. Miller, who has been given leave of absence to accept a teaching and research position at the University of Michigan. Dr. Chapman has been medical director of the regional office of the Department of Health, Education, and Welfare in New York City.

Dr. Richard F. Boyd, now medical director in the San Francisco regional office, will move to New York City, replacing Dr. Chapman. Dr. Charles F. Blankenship, now medical director of the Kansas City regional office, will move to San Francisco, replacing Dr. Boyd.

Dr. Lewis H. Hoyle, formerly regional health services consultant at the Kansas City office, replaces Dr. Blankenship as medical director of the office.

Public Health Service Announces New Program For Accident Prevention

THE NEW Accident Prevention Program of the Public Health Service, created July 1, 1956, is located in the Division of Special Health Services, Bureau of State Services. The program is directed by James L. Goddard, M.D. Chief of Program Services is Eugene L. Lehr, a sanitary engineer; chief nursing consultant is Jean F. Williams; and Albert P. Iskrant, a statistician, is chief of Operational Research.

Designed to serve State and local health departments through research, consultation, training, and information, the new program will devote much of the current year to planning in preparation for a considerably expanded operation in fiscal year 1958. In addition to its own staff, the program will use the services of personnel assigned by other interested agencies in the Department of Health, Education, and Welfare. A Departmental Advisory Accident Prevention Committee will help coordinate Departmental activities in the field.

Broadening the scope of the former home accident prevention program in the Bureau of State Services, the new program will, through use of the epidemiological approach, concern itself with the basic factors in accident causation and prevention and will enlist the competencies of all the disciplines in public health. The program will also assume responsibility for the former interests and activities of the Division of Sanitary Engineering Services in the hygiene of housing. Special attention will be directed toward developing guidelines and standards for incorporating basic safety and hygienic features into housing structures, including homes for special occupancy.

The accident category constituted the fourth leading cause of death in this country in 1955, and was actually the first cause of death for the age group 1-34 years. More than 90,000 persons died from accidents in 1955. More than 9,000,000 injuries are estimated to occur each year, causing more than 300,000 permanent impairments.

Since accidents are the result of forces from three sources—the host, the agent, and the environment—the public health procedure of epidemiological analysis, determination of causes, development of preventive measures, and evaluation may be applied in studies for preventing them.

Specialists from every field, including that of human behavior, can be used in the studies of the interrelationship of the forces and multiple causes that lead to accidental injury or death.

A 7-point work program has been set up as follows:

1. Collection and analysis of data.
2. Training (inservice, assignment, and formal).
3. Educational and informational services.
4. Experimental studies and epidemiological investigations.
5. Program demonstrations.
6. Consultation to official and voluntary agencies.
7. Aid to health departments in evaluating and setting up statistical procedures.

Other Departmental agencies cooperating with the new Accident Prevention Program are the Children's Bureau, Food and Drug Administration, Office of Education, and Office of Vocational Rehabilitation. Within the Public Health Service, the Bureau of Medical Services, the National Institutes of Health, the Division of Public Health Methods, and the National Office of Vital Statistics are all active in the work of the program.

Progress in Reporting Mental Hospital Statistics

*Sixth Annual Conference of
Mental Hospital Statisticians,
Topeka, Kansas, April 26-28,
1956*

THE STATISTICAL problems created by the widespread use of the tranquilizing drugs, comparisons of results of cohort studies, and measurement of degree of mental illness were major topics at the Sixth Annual Conference of Mental Hospital Statisticians. The conference, held at Topeka, Kans., April 26-28, 1956, was sponsored by the National Institute of Mental Health, National Institutes of Health, Public Health Service.

Delegates from the member States of the Model Reporting Area for Mental Hospital Statistics attended (see box inset). Washington was admitted as the 18th member State at this conference. In addition, unofficial observers from Massachusetts, North Dakota, and South Carolina, St. Elizabeths Hospital, Washington, D. C., and the Veterans Administration were present.

The Model Reporting Area for Mental Hospital Statistics was established in 1951 by mental hospital administrators and statisticians from 11 States. The organization's primary objective is to develop uniform procedures and definitions so that meaningful comparisons of mental hospital data among member States can be made. To meet the minimum requirements for admission a State (a) must have a central

statistical system to provide reporting from all of its State hospitals, (b) must have a professional statistician in charge of the statistical system, and (c) must agree to the definitions adopted by the Model Reporting Area and produce annually a minimum number of tabulations agreed to by the area States.

Dr. Morton Kramer, chief, Biometrics Branch, National Institute of Mental Health, opened the meeting by outlining some of the problems facing mental hospital statisticians. Among these, he mentioned the constant demand upon the statistician to justify current expenditures or to show the need for additional funds in view of the large mental hospital appropriations. He also discussed the importance of obtaining adequate data on the effect the increasing use of tranquilizing drugs is having on the Nation's mental hospital systems, and the need for controlled studies to test the effectiveness of these drugs.

Studies on Tranquilizing Drugs

Five delegates indicated that reporting procedures had been developed in their State mental hospitals to determine the number of patients placed on drugs, the number remaining on drugs, and the number from whom the drugs had been withdrawn. These reporting systems are expected to provide the foundation data for future studies of the effectiveness of the drugs. Several delegates reported on current drug studies and those being planned, none of which,

*Prepared by the Current Reports Section, Biometrics
Branch, National Institute of Mental Health, Na-
tional Institutes of Health, Public Health Service.*

however, involved the use of patients receiving placebos as controls.

Two basic difficulties for the statistician in his role in the studies of the drugs were raised: (1) All too often the statistician is called in to assist in a study after it has already been set up; and (2) frequently, the need for evaluation of such a program is not realized until long after the program has been in operation. In each the statistician is placed in a difficult position. He is often faced with the task of analyzing data obtained with inadequate experimental designs such as lack of control groups, or he may need information which is no longer possible to collect.

Recommendation of Rating Scales

The Committee on Psychiatric Impairment, appointed at the 1955 Conference of Mental Hospital Statisticians, reported on its recommendations concerning the development of scales to quantify the degree of mental illness.

A major difficulty in interpreting release rates from mental hospitals (that is, the proportion of first admissions who are released within a given interval following admission) is that such rates may be influenced by the severity of the patient's illness. Two hospitals having vastly different crude release rates may have identical severity-specific release rates. Thus, observed differences in release rates among all first admissions can be caused solely by a difference in distribution of types of risks entering the two hospitals. It is important, therefore, to obtain some measure of the severity of illness in patients at the time they enter the mental hos-

pitals and at intervals after admission in order to permit meaningful interpretation of release rates.

The committee recognized this need, particularly for purposes of comparing hospitals or hospital systems. It recommended that the National Institute of Mental Health, through consultation with appropriate professional groups, such as the American Psychiatric Association and the American Psychological Association, evolve rating scales, that the States make trial application of such scales in measuring severity of psychiatric disorders, and that the National Institute of Mental Health provide consultation services and material aid to States in the trial use of these rating scales.

The committee also emphasized that the rating of patients be made at least at time of admission and release and at such other intervals as deemed advisable. The scales to be used should be reliable, valid, sensitive, simple of application, and useful statistically. These characteristics are defined as follows:

Reliability—the degree of uniformity with which severity can be measured by different observers.

Validity—the ability of the scale to give results consistent with generally accepted clinical judgments of severity.

Sensitivity—the scale should be a sensitive measure of change in degree of severity.

Simplicity of application—the scale should be easy to use with professional guidance.

Statistical usefulness—the scale should be amenable to statistical classification and analysis.

The committee recognized that other patient characteristics and environmental factors were associated with psychiatric impairment. It was further recommended that attention be directed to the relationship between somatic impairments, household and community factors, and the admission of patients to and their release from mental hospitals. The report of the Committee on Psychiatric Impairment was approved and accepted by the conference.

Cohort Studies

At the 1955 conference, the Cohort Study Committee recommended that members of the Model Reporting Area conduct cohort studies of

Model Reporting Area States

Representatives from the following States are members of the Model Reporting Area for Mental Hospital Statistics.

Arkansas	Michigan	Oklahoma
California	Minnesota	Pennsylvania
Illinois	Nebraska	Texas
Indiana	New Jersey	Virginia
Kansas	New York	Wisconsin
Louisiana	Ohio	Washington

first admissions to State mental hospitals. These studies were to include all first admissions during a period of 3 months or more and were to follow these patients through their hospital experience for 1 year or until death or the first significant release, in order to determine for specified intervals of time, the proportion of first admissions released alive or remaining or dying in the hospital.

During the year, 10 States performed such studies. They reported the gross results at the conference. The percentage of patients released alive within 1 year following admission ranged from 50 to 90.

More detailed comparisons were not possible because the categories used by the various States were not comparable. For example, different age groupings were used by various States and some had further refinements, such as by sex and diagnosis, while others did not.

In view of these difficulties a new Cohort Study Committee, consisting of a statistician and clinician from each of 5 States, was appointed to review the cohort data and the methods of analysis used by the 10 States mentioned above. Each State will be asked to submit cohort data in a uniform manner to allow meaningful comparisons.

The committee will review these studies and meet to consider possible interpretations of interstate comparisons, taking into account as many known factors as possible. The committee will then report to the next conference its recommended interpretations of these studies and, perhaps, suggest further refinements to yield more meaningful analyses.

Uniform Financial Data

The need for uniform financial data was emphasized in a discussion of costs per patient. States are continually comparing their per patient maintenance expenditures with those of other States in order to demonstrate to legislators and the public the need for increased expenditures. It was pointed out, however, that such comparisons of expenditure data are often not valid. Some of these variations which cause noncomparability were noted in (a) policy with respect to inclusion or noninclusion of building and improvement expenditures in

maintenance costs, (b) the effect of climate on fuel and utility costs, (c) and the effect of institutional farm operations on food costs.

To circumvent some of these problems in comparisons of expenditure data, it was proposed by one of the States that total man-hours for treatment of patients be classified according to personnel categories such as physicians, nurses, social workers, attendants, and so forth. Under this proposal salaries of these employees would be related to the cost of living index for that region. Thus, per patient expenditures for salaries would be computed and adjusted according to the prevailing cost of living index. Interstate differences in salary levels for a given employee classification, after adjustment for regional differences in cost of living, might indirectly reflect differences in the skill, training, and general quality of such personnel. No specific action was taken on this proposal by the conference.

This problem of per patient cost has assumed sufficient importance to be of major concern to the Council of State Governments. The council, meeting with budget representatives of various States to consider these problems, has made specific recommendations. One called for the Council of State Governments to obtain the definition of "capital outlay" as used by the Bureau of the Census and determine whether it should be modified for mental health purposes. Another suggested that the States compute two sets of maintenance cost figures if they have psychopathic hospitals, one set to include and the other to exclude the maintenance figures for psychopathic hospitals.

The conference appointed a committee, consisting of statisticians from five States, to meet with comparable committees of the Council of State Governments to develop standards for determining the composition of maintenance expenditures. The committee is expected to report its progress at the next conference.

Other Problems

Considerable concern was expressed by some regarding the present nomenclature for mental defectives. A draft of the nomenclature which is an extension of the standard nomenclature was presented by one of the States. This revi-

sion is being applied in that State on a trial basis only. The conference agreed that this is an area requiring further study. It was suggested that States, as they attempt to solve difficulties in nomenclature, keep all the other States informed.

Monthly reporting of a few items concerning movement of mental hospital patients was suggested by one of the States. The objective of such reporting would be to provide simple data for studying current trends in mental hospital admissions, separations, and resident patient populations. It was proposed that a draft of a form for such reporting be prepared and submitted to the National Institute of Mental Health for circulation to the Model Reporting Area States for consideration.

Regional Meetings

The interest generated by these annual conferences has brought about the spontaneous

inauguration of regional meetings for mental hospital statisticians from neighboring States. Mutual problems, with special emphasis on interstate comparisons of mental hospital data, were considered. Since most States are interested in comparing data with neighboring States rather than with States far removed geographically, these meetings were felt to have been particularly helpful. Two such meetings were held in October 1955—representatives from 8 eastern States met at Princeton, N. J., and representatives from 7 midwestern States met at Chicago, Ill.

A questionnaire, requesting basic mental hospital data on a current basis, was developed and circulated by the midwestern group. The results were compiled, and a brief report on these comparative data was distributed. This report was found very useful by some of the States for presentation of material to their legislatures.

Home Safety Inventory

State health departments in 32 of 48 States participating are headquarters for the 1956 Home Safety Inventory sponsored by the National Safety Council. Public health agencies are represented in State safety councils serving as inventory centers in the 16 other States.

The basic purpose of the inventory is to help participating agencies let one another know what each is doing to prevent home accidents.

Local health departments will receive inventory forms in December from the State inventory centers. The value of the inventory will depend on how effectively local health departments complete and transmit the forms and report home safety activities of the past year. The information will be analyzed by punchcard devices. Duplicates of the completed forms will be given each participating State health department.

California's Experience in Training Public Health Physicians

By GEORGE T. PALMER, Dr.P.H., and MALCOLM H. MERRILL, M.D., M.P.H.

IT IS a well-accepted principle today that people entering the field of public health should have specialized training. Sedgwick at the Massachusetts Institute of Technology, Vaughan at the University of Michigan, and Abbott at the University of Pennsylvania were pioneers in establishing teaching centers for this purpose as far back as 1890.

Sedgwick's early work was focused principally on the field of microbiology and sanitary science. At that time and, in fact, for many years thereafter, there was doubt in the minds of some as to whether the medically educated worker really needed additional training in public health practice. Gradually, however, it became evident that the scope of a medical health officer's work went well beyond the field of medicine. Knowledge was also required in the fields of engineering, environmental sanitation, vector control, health education, social problems, community leadership, public administration, and laboratory sciences as related to public health as well as other fields.

In order to meet the growing need, schools of public health grew in number and in the scope of instruction offered. Through the years it has become increasingly evident that so far as medical health officers' training is concerned the limiting factor has been the provision of candidates for training. Recruiting of physicians

was materially facilitated, though not solved, with the provision of Federal funds for scholarships. These funds became available in California in 1936. The following report summarizes the experience in the training of physicians in California since that time.

Background of Study

During the period from September 1936 through June 1954, 86 physicians were granted scholarships by the California State Department of Public Health for the 8 or 9 months' course in a school of public health leading to the degree of master of public health. In a very few instances, field training in a local health department was provided for an extra period of 3 months. And in a few instances the scholarship was granted after the beginning of the term and thus did not cover the full period of 9 months.

Training was carried on for the 6 years 1936 through 1941, and then was discontinued during the war years of 1942 through 1945 because of lack of candidates. The scholarship program was renewed in 1946 and has continued without interruption to date. However, no candidates were available for the academic year 1952-53. Thus, this review represents 13 training years.

Omitted from the tabulations that follow are 12 physicians, the 6 who completed training in June 1955 and another 6 who concluded training in June 1956. All of these were promptly placed in local health departments in California.

Dr. Palmer is consultant in public health training and administration and Dr. Merrill is director of the California State Department of Public Health.

Table 1. Years served in public health or related field by physicians whose training was sponsored by the California State Department of Public Health, September 1936-June 1954

Number of trainees, field, and length of service	In California June 1954	Have been in California but not present June 1954	Never in California	Total	Percentage distribution of total possible years of service less death years

Average years per trainee:					
In California.....	8.8	5.1	-----	-----	-----
In total government service.....	9.4	7.3	10.0	8.6	-----

The gathering of the basic data has been difficult and time consuming owing to the inadequacy of complete detailed records for the period prior to 1947. We drew on the knowledge of workers long with the State health department and made extensive inquiries of trainees through correspondence. However, accuracy in all particulars cannot be assured. In assembling costs of scholarships, we used the amount prevailing at the particular period when the specific individual amounts were not definitely at hand. The figures used, we believe, are a fair estimate.

Services After Training

A study was made of the subsequent history of employment of the 86 physicians who received training under the program. Special attention was given to determining the number of years after training that each physician continued in full-time public health work, both in California and elsewhere (table 1).

Still in public health or related public health services in California are 49 of the 86 trainees. The term "related" refers to employment other than in health departments, such as teaching

in schools of public health or universities or work in various voluntary health agencies or public health associations.

Since receiving training, some of the 49 physicians who were engaged in public health work in California in 1954 have been in health service for one or more years in other areas of the country or in foreign or military service or in private practice.

All but 3 of the 86 have at some time since training spent one or more years in public health or related service in California. There has been an understanding between the scholarship recipient and the State health department that upon completion of training the trainee would accept a position in a California health department and remain in this type of employment for a minimum period of 2 years. The three who have not done so have given justifiable reasons, such as unexpected family circumstances, illness, or compelling calls to foreign service. In one of these instances, the entire amount of the scholarship was repaid to the State.

In addition to the 49 employed in California in 1954 and the 3 mentioned above, 34 trainees who were employed elsewhere in 1954 or who

had died (4 in number) had previously spent a total of 174 years in California service.

Altogether, the 86 trainees have spent 606 years in health service in California, 59 years in health service in other areas of the country, 19 years in foreign service, 56 years in military service, 130 years in private practice, and 19 years in other fields of work.

The total possible years of service (18 years per person for those finishing their training in 1937, 17 years for those finishing in 1938, and so on) is 930. However, 41 years must be deducted for years lost through premature death, thus converting this figure to 889 years.

The 606 service years spent in public health or work related to public health in California represent 68 percent of the 889 possible years. However, if to the 606 years are added the service in other States, foreign, and military service, 740, or 83 percent, of the possible 889 years were spent in government service.

Of the 15 percent of total possible years spent in private practice, it may be said that, although not spent in strictly public health service, undoubtedly there were substantial and worthwhile gains in an understanding cooperation with public health services stemming from the active years spent in this field.

Of the 18 trainees in private practice in 1954, 16 received their public health training prior to 1942. Only two trainees in the training period from 1946 on were in private practice in 1954.

Cost of Training

The average cost of a scholarship for the 86 physicians during the 13 years of the program

was \$2,910 per person (table 2). Excluded from this sum are operating and administrative costs. The largest item was for stipends, or living expenses, which amounted to about \$222,700. The approximate total for tuition was \$17,300 and for travel, \$10,000. The total is thus about \$250,000. For this sum, the taxpayers have already received 740 man-years of professional medical public health service. This length of service represents an average cost per trainee of approximately \$338 per year thus far. The figure will decrease, of course, as the years of service increase.

The financial support of the training program for physicians, as well as for other professional personnel not here indicated, has come from Federal funds throughout the entire period with the addition of State funds for the 2 years 1948-49 and 1949-50.

The cost of scholarships have varied considerably over the years. This has been due to a number of changing circumstances, including changes in amount of scholarship allowance reflecting economic changes; the location of the training school, with higher travel and tuition costs for eastern schools; and the change in policies in later years whereby costs in eastern schools were limited to the equivalent of the California school.

The 86 physicians received their training in 8 universities as follows:

California	46	Michigan	4
Harvard	17	Minnesota	2
Johns Hopkins	10	Columbia	1
Yale	5	Vanderbilt	1

It is of interest to note the wide participation of schools of public health throughout the coun-

Table 2. Scholarship costs for physician training in public health

try in contributing to the education of California scholarship students.

Discussion

It is believed that the money invested by government in the training of public health physicians in California has been a most valuable investment. While only 68 percent of the 889 possible years of service were spent in public health in California, it is significant that 83 percent of the possible years were spent in government service, either within or outside continental United States. Since the funds were derived primarily from a national source, it is not unreasonable to include service in the general public health field as representing returns on the investment. Taking this into consideration, the average cost to government per year of service of the medical officers covered in this study has been approximately \$338 for the 740 man-years to date. When it is considered that in the California public health situation physicians thus trained are for the most part responsible for the administration of State and local public health programs involving the expenditure, at present, of between \$40 and \$50 million annually, the true significance of the government's investment in training is apparent.

Most of the physicians leaving the public health field were trained prior to 1946. This loss occurred during the unsettled conditions of World War II with the resulting intensification of competitive bidding for the services of these physicians. Since the 1946 period, there has been a distinct change in the status of the public health profession, the development of the Specialty Certification Board in Preventive Medicine, and more attention on the part of the public to provision of better salaries for career public health physicians. The stabilization of public activities has contributed to making a career in public health more attractive as a continuing profession for physicians once they are recruited into the field.

Recruitment, however, is still a difficult problem. The limited number of available scholarships is a vital restriction. In California, for example, with due regard for the training of other professional personnel, there are but six

scholarships per year currently available for physicians. It is estimated that at least 10 physicians will need to be trained annually in order to take care of replacements and expanding public health activities in the State.

It is becoming increasingly evident that the only way sufficient physicians can be recruited to the public health profession will be through the provision of a planned program of training that will carry them through the academic year of postgraduate education in public health plus 1 year of residency in an approved health department. With this background they will find employment opportunities that will add 1 year of supervised field experience in public health and 3 years of public health practice. After completing these 6 years of training and experience in preventive medicine and public health, physicians will be eligible for certification by the American Board of Preventive Medicine.

Summary

1. Since 1936, 86 physicians have been granted scholarships by the California State Department of Public Health for academic training in public health.

2. Of these 86 physicians, 49 are still engaged in full-time public health or related public health work in California, and 34 others have been at some time in public health work or related service in California.

3. Of the 889 possible years since completing training, the 86 trainees have devoted 740 man-years, or 83 percent, of the possible years in government service; 606 of these service years have been spent in public health or related work in California.

4. The total cost for training the 86 physicians has been \$250,000. If spread over the subsequent years of service in the public health field until June 1954, this amount represents a cost of approximately \$338 per year of service.

5. Eight different schools of public health were utilized in the training of these candidates.

6. It is concluded that this has been a sound investment on the part of government.

7. The need for further extension of this type of training program is indicated.

Etiology of 1954-55 Poliomyelitis Epidemic in Puerto Rico

By DAVID H. NAIMARK, M.D., and NANCY G. ROGERS, B.A.

DURING the latter part of 1954, paralytic poliomyelitis appeared in epidemic form on the island of Puerto Rico. This epidemic became one of the largest outbreaks of poliomyelitis in the recorded history of the island with some 500 cases reported from November 1954 through June 1955.

At the request of the Secretary of Health, Commonwealth of Puerto Rico, plans were made early in December 1954 for viral studies on a representative group of pediatric patients. The laboratory data obtained from this study during the height of the epidemic supplements a preliminary epidemiological report (1).

Methods

Cases of paralytic poliomyelitis admitted to the pediatric service of Bayamon District Hospital in Puerto Rico relatively soon after onset of their disease were chosen for study. The hospital staff selected 16 patients, ranging in age from 1½ months to 7 years, collected the appropriate specimens, and prepared case summaries. Materials for collection of specimens

were supplied by the Tropical Research Medical Laboratory, United States Army, San Juan, Puerto Rico. The responsibility for handling, storing, and shipping specimens fell to this same installation. Diagnostic laboratory studies for poliomyelitis were performed by the Department of Virus Diseases, Walter Reed Army Institute of Research, Walter Reed Army Medical Center, Washington, D. C.

Initial blood samples were drawn shortly after hospital admission, and subsequent specimens were taken on the 14th to 21st days of disease. Throat and rectal swabs were obtained during the first few days of hospitalization. In fatal cases, generous blocks of tissue were taken from several areas of the brain in addition to a portion of the cervical spinal cord.

Blood drawn in Keidal vacuum tubes was stored overnight at 4° C. Serum was then separated from the clot and maintained in the frozen state until used for serodiagnostic procedures. Throat and rectal swabs were individually placed in sterile screw-capped tubes containing 1 milliliter of veal infusion broth. These were promptly frozen and maintained at -70° C. (dry ice) until thawed for tissue culture inoculation. Central nervous system tissues were aseptically removed at time of autopsy, placed in tightly sealed (screw cap) wide-mouth bottles, and also stored at -70° C. Materials thus collected, and accompanying clinical and laboratory summaries, were periodically shipped in dry ice via air express to the

Walter Reed Army Institute of Research for laboratory study.

Serums were tested for neutralizing antibodies against the three types of poliomyelitis virus by a modification of the tissue culture metabolic inhibition procedure described by Salk and associates (2). The test, as performed, contained serial twofold dilutions of the patient's serum, approximately 100 to 300 tissue culture ID₅₀ (3) of one of three prototype poliomyelitis viruses (Mahoney, type 1; Y-SK-7, type 2; and D-3-83, type 3), and a suspension of trypsin-dispersed monkey kidney epithelial cells (4).

For attempted isolation of virus, broth suspensions of throat and rectal swab specimens were first centrifuged at 2,000 r.p.m. for 30 minutes. The supernatant fluids were treated with sufficient penicillin and streptomycin to bring the final concentration to 1,000 units and 1,000 micrograms per milliliter, respectively. After incubation from 30 minutes to 1 hour at room temperature, individual suspensions were inoculated in 0.1 milliliter amounts into each of 2 or 3 tubes containing tissue cultures from monkey kidneys. Blocks of central nervous system (CNS) tissue from the various anatomical areas were pooled, made into a 20 percent suspension with chilled distilled water, and then processed and inoculated as above.

Inoculated tissue culture tubes were observed daily for microscopic evidence of cytopathogenic effect. If no degeneration was seen after 14 to 21 days, one blind passage of cells and fluid was made and these subcultures observed

for a similar period of time. When definite signs of specific cellular degeneration occurred, the tissue culture fluid was harvested and inoculated into a "spot neutralization typing test" as described by Melnick and others (5). In this procedure, samples of infected "unknown" fluid were mixed separately with poliomyelitis type-specific monkey hyperimmune serums. Following incubation, these mixtures were each inoculated into two tissue culture tubes and incubated at 37° C. for several days. Preliminary identification was accomplished if protection occurred in the tubes containing one monotypic antiserum but not in the tubes containing the other two antisera or in the control cultures. In each instance, the procedure promptly identified the cytopathogenic isolate as a strain of poliomyelitis virus, and it was unnecessary to perform quantitative neutralization tests.

Specimens from the 16 patients studied were obtained during December 1954 and January 1955. Nine of these patients died while the seven survivors exhibited definite paralytic manifestations. All 16 patients lived within a 10-mile radius of the hospital, but several cities were represented; 7 resided in Toa Baja, 5 in Catano, 3 in Bayamon, and 1 in San Juan.

Results

Virus isolation attempts using central nervous system tissue were successful in 6 of the 9 fatal cases, with recovery of type 1 poliomyelitis virus in each instance (table 1).

Throat and rectal swab materials were avail-

² Single serum samples only were available.

able from 3 of the patients who died and from all 7 surviving patients (tables 1 and 2). In only two instances were isolation attempts successful with these specimens; one strain was obtained from rectal swab material and another from a throat swab. Each of the two agents proved to be type 1 poliomyelitis virus (table 2). Although throat and rectal swabs failed to yield virus in the three fatalities, viral recovery was possible when CNS tissue specimens were used.

Paired serums were available for 5 of the 7 paralytic patients (table 2). Serologic tests revealed a significant rise in neutralizing antibody titer (fourfold or greater) in 3 of these instances (patients 12, 13, and 14). Although no significant increase in antibody was shown with the remaining two paired serums (patients 10 and 11), it should be noted that only type 1 antibody was present, and in each case a type 1 virus was recovered from either the rectal or throat swab. Convalescent serums only were obtained from the remaining two paralytic patients. Both were 8-month-old infants and their serums neutralized type 1 but not types 2 or 3 poliomyelitis virus.

Discussion

All 6 of the 9 fatal cases from whom virus was recovered from the CNS died by the third day of hospitalization, which was still within a few days following onset of illness. Two of

the three patients from whom isolation attempts were unsuccessful died relatively late in their illness (one on the 21st and the other on the 57th day of disease). The one remaining CNS specimen was considered unsatisfactory for study because of heavy bacterial contamination. In all nine of the fatal cases microscopic examination of brain and cord tissue resulted in a pathological diagnosis of poliomyelitis. (Gross and microscopic pathological examinations were done under the supervision of Dr. Gerardo B. Polanco, Bayamon District Hospital). It is of course not surprising that no virus could be recovered from the two patients dying late in the course of the disease since general experience has shown that virus can rarely be recovered from the CNS after the second week of disease (6).

It is of some interest that isolation attempts were successful in only two instances with throat and rectal swab specimens although presumably all such samples were taken from paralytic poliomyelitis patients. One must consider the possibility that the nasopharyngeal secretions contained little or no virus or perhaps neutralizing antibodies when these samples were obtained; yet, no such explanation suffices for the rectal swabs. More plausible explanations are, perhaps, that only small amounts of throat secretions or fecal materials were obtained thus causing virus dilution to be a critical factor (1) or viral inactivation

occurred in the tubes of broth under conditions of subsequent handling and shipment (2), or both. These observations appear in general agreement with those of Godenne and Riordan in a recent publication (7). They noted that throat and rectal swabs were not ideal specimens for routine poliomyelitis virus isolation attempts.

Demonstration of a significant antibody titer rise between paired serum specimens enabled a diagnosis in three surviving patients. The four remaining surviving patients were shown to possess neutralizing antibodies for type 1 virus alone. This assumes additional significance when one considers that each was convalescing from an attack of acute paralytic disease, and furthermore, in two such instances the children were less than 1 year of age.

Summary

Type 1 poliomyelitis virus was isolated from 6 of 9 patients who died and from 2 of 7 survivors studied in the 1945-55 outbreak of acute paralytic disease in Puerto Rico. A diagnostic increase in neutralizing antibody titer for type 1 virus was demonstrated in 3 of the 7 surviving

patients, while the remaining 4 possessed antibodies for this type virus alone.

National Advisory Council on Health Research Facilities

Marion B. Folsom, Secretary of Health, Education, and Welfare, has appointed 12 members to the new National Advisory Council on Health Research Facilities. The council assists the Public Health Service in administering a program of Federal grants for construction of medical research facilities.

The advisory council, established in the new law, includes 8 leading medical, dental, and scientific authorities and 4 members to represent the public. The Surgeon General of the Public Health Service and an official of the National Science Foundation are ex officio members, with the former serving as chairman.

Members of the council are: Dr. George N. Aagaard, Seattle, Wash., professor of medicine and dean of the University of Washington School of Medicine; Eugene N. Beesley, president, Eli Lilly and Co., Indianapolis, Ind.; Dr. Thomas H. Hunter, dean, University of Virginia School of Medicine,

Charlottesville; Dr. Carlyle Jacobsen, executive dean for medical education, State University of New York.

Dr. Paul C. Kitchin, professor of dental histology and embryology, Ohio State University School of Dentistry, Columbus; Dr. Oliver H. Lowry, dean, Washington University School of Medicine, St. Louis, Mo.; Dr. Robert A. Moore, vice chancellor, University of Pittsburgh; F. C. Sowell, vice president and general manager, radio station WLAC, Nashville, Tenn.

Dr. John E. W. Sterling, president, Stanford University, Calif.; Dr. Thomas B. Turner, professor of microbiology, School of Hygiene and Public Health, Johns Hopkins University, Baltimore; Dr. James W. Wilson, professor and chairman, department of biology, Brown University, Providence, R. I.; and James Bradshaw Mintener, former Assistant Secretary of Health, Education, and Welfare.

How much of each lot of vaccine must be tested to provide reasonable assurance of its safety? This paper considers some of the statistical issues associated with this question and, in the process, develops the concept of the consistency of a production process.

Some Statistical Aspects of Safety Testing the Salk Poliomyelitis Vaccine

By JEROME CORNFIELD, MAX HALPERIN, Ph.D., and FELIX MOORE

MANY circumstances can influence the safety of any lot of vaccine. They may be conveniently considered as falling into two distinct classes. The first consists of all those circumstances affecting the ability to produce a safe vaccine, the second those affecting the ability to detect an unsafe vaccine. Problems involving the second class of circumstances we shall refer to as problems of safety testing. In practice the safety of the vaccines released for general use will depend on the successful solution of both sets of problems, and it would be hazardous to place reliance for safety exclusively on either one of the two. Nevertheless, in formulating criteria for safety testing, it is useful to inquire into the amount of testing re-

quired to assure a high level of safety without making any assumptions about the safety of the production process. This is equivalent to asking whether it is possible to assure a high level of safety by testing alone, even under the most unfavorable production circumstances that one can envisage. While we shall not be able to answer this question definitively, it will be because of the lack of key biological information and not because the problem is analytically insoluble or even necessarily that the solution, given the key information, would require impracticably large amounts of testing.

Vaccine Preparation

We begin by reviewing briefly those aspects of vaccine preparation and the minimum requirements for safety testing (1) which are pertinent to the subsequent discussion. There are three immunologically distinct forms of poliomyelitis virus. An attack by type 1 virus will confer immunity against further infection by that type but not necessarily against infection by type 2 or type 3. Since the vaccine must provide protection against all three types, it must contain antigens for each. A vaccine prepared from a single virus type is referred to as a single-strain vaccine, while a trivalent

The authors are all with the National Institutes of Health, Public Health Service. Mr. Cornfield is assistant chief of the Biometrics Branch of the Division of Research Services. Dr. Halperin is chief of the Biometrics Office, Division of Biologics Standards, and Mr. Moore is chief of the Biometrics Research Section of the National Heart Institute. They presented this paper at the 115th Annual Meeting of the American Statistical Association, held in New York City December 28, 1955.

vaccine, the form in which the vaccine is actually used, is a combination of equal amounts of three single-strain vaccines.

Each batch of single-strain vaccine is prepared from a virus pool obtained by propagation on cultures of monkey kidney tissue. The pool is filtered and then tested for infectivity. If sufficiently infective for tissue culture, it is ready for the next step, the preparation of vaccine. A pool is considered sufficiently infective if 0.5 cc. is capable of infecting tissue culture after at least a one-millionfold dilution. The amount by which a preparation must be diluted before it loses infectivity is referred to as its titer. There is, in fact, no single dilution point at which infectivity turns abruptly to noninfectivity, and in practice the titer used is that dilution estimated to result in infectivity for 50 percent of the inoculated tissue culture tubes. The amount of virus present in an inoculum capable of infecting 50 percent of the tubes is referred to as one tissue culture infectious dose (TCID₅₀).

In practice it is more convenient to work with log titers than with titers. We thus say that a virus pool is ready for the next step when its log titer is at least 6. In the next step the pool is exposed to formaldehyde at a temperature of 37° C. and heated for 6 days or more. The preparation loses infectivity continuously but still retains the ability to stimulate antibody production. At intervals during this inactivation process samples are taken and the titer of 0.5 cc. determined. At some point during the process, usually 2 to 3 days, the titer has dropped from at least 1 million to unity, that is, after 2 to 3 days the 0.5 cc. of the preparation, if diluted at all, will infect less than half the tubes into which it is inoculated. Unless one uses larger inoculums or concentrates the preparation, the log titer cannot be easily determined for any period after this time. The curve relating log titer to time heated is referred to as an inactivation curve.

Subsequent to theoretically complete inactivation, tissue culture safety tests are performed. The current tissue culture safety test requires two independent tests of 500 cc. each for each single-strain vaccine, the first test 6 to 9 days after the initiation of inactivation, the second 3 days after the first. In addition, 1,500 cc. of

each trivalent vaccine must be tested. The test batch is passed if it produces no tissue changes indicative of the presence of live virus and in addition passes a monkey safety test. This latter test requires that each filling of the final trivalent lot must be tested on at least 5 monkeys, a minimum of 20 being used for each lot. Each monkey receives 2.5 cc. of vaccine. The lot is passed if histological and other studies on the test monkeys "leave no doubt that poliomyelitis infection did not occur" (1).

Shape of Inactivation Curve

To point up the difficulties that can arise when exclusive reliance is placed upon the safety of the production process rather than on the adequacy of the safety test, we consider Salk's original concept of factors affecting safety. As elaborated in several publications, the chief guarantee of the safety of the final vaccine was not felt to be the result of a monkey or tissue culture safety test but rather the nature of the inactivation process itself. Thus, it was observed that if log titer was plotted against time of exposure over the observable period, that is, the first 2 or 3 days, that log titer was a linear function of time. Figure 1, which has been adapted from one of the discussions of

Figure 1. Theoretical relationship between log titer and inactivation time.

this point subsequently published by Salk (2), illustrates this point with a theoretical inactivation curve in which log titer is assumed to drop from an initial value of 6 to 0 in $2\frac{1}{2}$ days. Salk has written (2) that the linear nature of this relation "makes possible the prediction, rather precisely, of the time required to render each preparation free of living virus." Thus, in the initial virus pool one tissue culture infectious dose could be found in as small amount as one two-millionths of a cubic centimeter. By $2\frac{1}{2}$ days one would find one TCID₅₀ only in every half cubic centimeter, and, by simple extrapolation, by 6 days only one in every 125 million cc. Again quoting from one of Salk's publications (3) "[if] the reaction is allowed to proceed for a total period equal to three times the interval required for interception of the base line . . . the margin of safety which guarantees absolute safety has been assured."

The assumption that log titer was a linear function of inactivation time was not an entirely empirical one, simply suggested by inspection of data, but a relationship often found in theoretical chemistry. If the inactivation process is thought of as a chemical reaction analogous to a situation wherein one molecule of virus combines with one molecule of formaldehyde, the latter being present to excess and consequently not limiting the speed of the reaction, then the relationship between log titer and time would indeed be linear, if the system was homogeneous (4). Whatever the merits of this formulation from the point of view of inactivation kinetics under controlled laboratory conditions, the occurrence of lots of vaccines containing live virus, even after 9 days of inactivation (5), indicated that extrapolation of the inactivation curve was no substitute for safety testing.

It is not hard to see why the extension of results possibly applicable in a homogeneous system to a potentially heterogeneous system might cause difficulty. Thus, figure 2 compares the inactivation curves obtained for two different hypothetical heterogeneous systems with the linear inactivation curve of the preceding figure. In the first curve we have assumed a heterogeneous system with two groups of virus particles, each being inactivated at different rates. One group is assumed to have an initial titer of 10^6 and a loss of log titer of 2.4 per

Figure 2. Theoretical virus inactivation curves for three different models of the inactivation process.

day, the other an initial titer of 10^{-2} , but it is assumed to have no loss in activity as the reaction proceeds. Such a situation could occur if the bulk of the virus particles were being inactivated as in a monomolecular reaction, but a small fraction, $1/1,000,000$, were protected from the action of the formaldehyde by tissue particles. It will be noted that in such a situation the observed inactivation curve would be virtually indistinguishable on any basis from a linear inactivation curve for the first $2\frac{1}{2}$ days, but that thereafter it would level out quite rapidly and, no matter how protracted the time of inactivation, would remain at a level of one TCID₅₀ for every 50 cc., a highly infectious level. The shape of the inactivation curve for the observable period would in such a situation provide no guide to the subsequent course of the reaction.

In the second curve we have also assumed two groups of particles being inactivated at different rates. The first group is assumed to have an initial titer of $10^{5.97}$ and to undergo a loss in log titer of 2.4 per day. The second group is assumed to have an initial titer of $10^{4.81}$ and to undergo a daily loss in log titer of 1.47. Some curvature in the observable period will be noted. After 2 days of inactivation this curve is 0.8 of a log titer above the first curve, but it does not

level off as rapidly, eventually crosses it, and at 6 days has one TCID₅₀ in every 5,000 cc. Looking only at the observable period, one might place confidence in the eventual noninfectivity of the hypothetical vaccine producing curve 1 and might have serious doubts about the one producing curve 2. Nevertheless, after 6 days of treatment the second vaccine would have only 1/100 the concentration of infectious particles of the first.

These are, of course, only highly oversimplified models of what might happen. The real question is what does happen. To answer this we consider five successive lots of vaccine produced by a single manufacturer. These lots were composed of 104 independently produced and tested single-strain components. Of these, 12 had failed their initial tissue culture test after inactivation was presumably complete and the remainder had passed. We have taken all 12 of the positive components and a haphazardly selected sample of 17 of the 92 negatives. Least squares parabolas have been fitted to each of the 29 inactivation curves. The following tabulation shows for each of the curves the value of the quadratic component at 50 hours for positive and negative lots.

Negative lots		Positive lots	
1. 22	0. 66	1. 25	1. 86
1. 82	0. 10	0. 38	0. 22
1. 41	0. 59	0. 85	1. 16
0. 87	0. 63	-1. 59	1. 34
1. 84	0. 28	0. 94	0. 47
-1. 25	0. 57	0. 21	0. 85
0. 07	1. 16		
2. 00	0. 91	Average...0. 66	
-0. 11			
Average...0. 75			

NOTE: The quadratic component is the value of ct^2 , with $t=50$, where $\log \text{ titer} = a + bt + ct^2$ and t is time in hours.

It will be noted that the value of the quadratic component is less than zero in only three cases, two for negative lots and one for a positive lot. In all other cases the quadratic term is positive, indicating that the best fitting parabola curves up and away from the linear component and that a linear extrapolation will underestimate log titer. The average value of the component at 50 hours, 0.75, involves about the same departure from linearity at that point as does curve 2 of figure 2. The antilog of this value, 5.6, indicates that at 50 hours a difference of

more than fivefold in estimated titer had already developed between the best fitting parabola and its linear component.

The fundamental point, however, is that no difference is apparent in the value of the quadratic component for positive and negative lots. Theoretical considerations and actual experience both lead to the same conclusion therefore—that the shape of the inactivation curve up to a certain point provides no necessary indication of its shape thereafter. One can also draw the more general conclusion that no matter how safe a production process is believed to be, common prudence requires safety testing procedures which have high probability of detecting the presence of live virus particles, if by some unforeseen chance the production process permits this to happen.

Size of Test Batch

In many problems of industrial sampling inspection, a decision as to how much to sample is reached by minimizing the monetary loss arising from a combination of testing cost and the costs arising from erroneously rejecting good lots or accepting bad lots of a product (with due regard for the a priori probability that a lot will be bad) (6). But in the present problem the loss arising from erroneously accepting an infectious lot is entirely incommensurable with the cost of testing or with the cost of erroneously rejecting good lots. This suggests that the methods of industrial sampling inspection cannot be applied to the present problem without some modification if they can be applied at all.

We may approach a solution by considering first of all an idealized suspension of virus particulates of which we may assume that (5):

1. The particulates are randomly and independently dispersed throughout the suspension.

Second, we consider an idealized test system for which we may assume that:

2. One particulate is an effective dose and when introduced into the test system will invariably make its presence known by eliciting some characteristic response.

Since our immediate interest is the logical structure of the problem of safety testing, we

defer to a subsequent section a discussion of the correspondence, if any, between (a) the idealized viral suspension and an actual vaccine containing residual live virus and (b) the idealized test system and the tissue culture and monkey tests actually used. In this and the following section the "lots" referred to are assumed to have the characteristics of this idealized suspension.

The first assumption is sufficient to assure that if a test volume of v cubic centimeters is taken from a suspension containing m particulates per cubic centimeter (infection level m) the probability that the sample will contain exactly x particulates is given by the general term of the Poisson distribution, namely:

$$e^{-mv} \frac{(mv)^x}{x!} \quad [1]$$

This is true when the volume of the suspension (V) is large relative to the volume of test sample (v), as we shall assume in what follows. When this assumption cannot be made (7), the required probability is the general term of the binomial distribution, namely:

$$\binom{mV}{x} \left(\frac{v}{V}\right)^x \left(1 - \frac{v}{V}\right)^{mV-x} \quad [2]$$

The second assumption says that the probability of detecting growth in the test system is identical with the probability that the test volume contains one or more particulates, namely:

$$\sum_{x=1}^{\infty} e^{-mv} \frac{(mv)^x}{x!} = 1 - e^{-mv} \quad [3]$$

Thus, in testing v cc. from a suspension at infection level m the probability of an erroneously negative test is e^{-mv} . By varying v and m it is possible to explore numerically the probabilities of erroneously accepting suspensions at different infection levels and using different sample sizes. For example, if one tests 500 cc. from a suspension containing 5 particulates per 1,000 cc. the probability of a negative result is 0.08, since

$$e^{-(.005)(500)} = .082$$

Thus, 8 percent of all suspensions at this infection level would pass a test using 500 cc.

The minimum requirements imply that 1,500

cc. of each single strain vaccine will be tested on tissue culture and at least 50 cc. more on monkeys. If assumptions 1 and 2, held for both tissue culture and monkey tests, the additional safety assured by the 50 cc. could for the purposes of this calculation be disregarded. In that case the probability of passing a single-strain pool at infection level 5 per 1,000 cc. would be

$$e^{-(.005)(1000)} \times (\text{probability of a negative in the 1,500 cc. in the trivalent pool})$$

If the infection level for the trivalent pool is also assumed to be .005, this gives a final probability of a false negative of $e^{-(.005)(2000)}$.

Thus, the probability of accepting single-strain pools containing 5 virus particulates per 1,000 cc. would be less than 1/100,000 if assumptions 1 and 2 were satisfied. This is the probability given in the White Paper for passing a single-strain vaccine produced at infection level 5 per 1,000 cc. (5a).

Consistency

There are a number of questions that can be raised about this formulation. We note first that it appraises a lot solely on the basis of the evidence furnished by that lot and makes no use of prior information on the consistency or inconsistency with which negative lots have been produced in the past. In practice the Public Health Service's Technical Committee on Poliomyelitis Vaccine, which must approve each lot before it is released, has "been influenced as much by the plant record for consistency of performance as by the negative results of tests on the individual lots considered" (8). But there has been no precise criterion of what is meant by consistency. This is the question to which we now turn.

We start by borrowing a concept from the literature of quality control and consider the average outgoing quality of lots passing the new safety test. More precisely we ask: What is the probability that a cubic centimeter of a suspension passing the safety test will contain some specified number of particulates, say one or more? Making the same two assumptions as were made earlier we find that no answer to this

question is possible because we do not know the infection level at which any given vaccine is produced. Suppose, for example, that all lots being produced by a manufacturer contain exactly one particulate per liter. Then no matter what the safety test, so long as any lots at all are passed, the outgoing lots will also contain one particulate per liter. In such a case, of course, a considerable proportion of batches submitted would fail the safety test, and it is unlikely that anyone, producer or tester, would feel any great confidence in the safety of the batches that passed. This example suggests that if one wishes to control the probability that an outgoing cubic centimeter contains live virus, one must consider not only the lot being tested but also the past history of testing, that is, the consistency with which safe lots have been produced. It also suggests a general way of proceeding.

Subject to the assumptions made earlier let us initially consider a manufacturer producing a single-strain pool at constant infection level m . Denote the probability that a cubic centimeter contains one or more particulates infectious for the test system by P . Then

$$P = 1 - e^{-m} \quad [4]$$

We shall henceforth refer to P as outgoing quality. Denote the probability that a batch produced at this level of infection will pass when v cc. are tested by Y . Then

$$Y = e^{-mv} \quad [5]$$

and

$$P = 1 - Y^{1/v} \quad [6]$$

For this simplest situation we thus have a relation between the probability that an outgoing cubic centimeter contains one or more particulates, P , and the proportion of lots, which pass, Y , for constant test level, v . P is a quantity that we wish to keep below some minimum level; the amount tested, v , is subject to our control; and Y , the proportion of lots passed, can be estimated from past experience. As it stands the model is too simple to be realistic, but solely in the interests of understanding its implications let us explore it numerically. Suppose we set P at some low level, say $5/100,000$ and consider $v=4,500$, that is, we consider the

entire testing process to consist of a single test of 4,500 cc. of the final trivalent pool. We then have

$$5 \times 10^{-5} = 1 - Y^{1/4500}$$

Solving, we obtain $Y=80.0$.

That is to say, if a manufacturer is producing lots at a constant but unknown level of contamination, and if 4,500 cc. of each batch are tested and 80.0 percent pass, then, given the assumptions previously made, it follows that out of every 100,000 cc. released, 5 would be expected to contain one or more live virus particulates.

If now under this model we wish to assure that the probability of live particulates in a cubic centimeter of passed vaccine never exceeds $5/100,000$, we pass a lot if, and only if: (a) the lot under consideration passes a safety test involving 4,500 cc.; and (b) at least 80.0 percent of previously tested lots have passed.

In practice we should, of course, wish to safeguard ourselves against a number of contingencies, perhaps the most important of which is that the level of m fluctuates from time to time. In that case one might wish to use only recent production information in estimating the value of Y for a producer. Suppose, for example, one looked at only the last 10 lots produced. If the probability of a negative were in fact constant and equal to .8, then the probability of passing all 10 is .11, which is rather high and suggests that a run of 10 negatives is not too improbable even for a Y less than .8. The probability of passing 20 out of 20 when $Y=.8$ is, however, .012, while the probability of failing 1 out of 20 is .058. One might thus regard 20 negatives out of 20 as evidence at approximately the .99 level of confidence that Y was at least equal to .8 and at least 1 positive out of 20 as evidence at this level that Y might be below .8. An amended procedure for providing that the probability of live particulates in a cubic centimeter from passed lots does not exceed $5/100,000$ would be to pass a lot if, and only if, it formed part of a run of 20 negative lots. More generally if we denote by n the size of the run of negative lots required, we have

$$n = \frac{\log a}{v \log (1 - P)}$$

where $(1-a)$ is the level of confidence.

Size of negative run (n) required to insure given confidence $(1-\alpha)$ that average outgoing infectivity per cubic centimeter is less than P [for selected values of α , P , and test volume, v].

$(1-\alpha)$	$P=1 \times 10^{-3}$	$P=5 \times 10^{-3}$	$P=25 \times 10^{-3}$	$P=50 \times 10^{-3}$
$v=1,000$				
.95-----	303	60	12	6
.99-----	465	92	18	9
.999-----	698	138	28	14
.9999-----	930	185	37	18
.99999-----	1,162	231	46	23
$v=5,000$				
.95-----	61	12	2	1
.99-----	93	18	4	2
.999-----	140	28	6	3
.9999-----	186	37	7	4
.99999-----	233	46	9	5
$v=10,000$				
.95-----	30	6	1	1
.99-----	47	9	2	1
.999-----	70	14	3	1
.9999-----	93	18	4	2
.99999-----	116	23	5	2

We show in the table above the values of n for various levels of confidence, sample volumes, and levels of outgoing quality.

The rule derived is in a general way consistent with recent practice in accepting and rejecting lots. In the 1954 field trials, however, its use would have led to the rejection of the two lots whose production was preceded and followed by lots which tested positive. The lots which tested positive were discarded, but the two lots sandwiched in between were used in the field trials, a practice inconsistent with any consistency rule. (A rereading of the slides which led to calling these lots positive has, in the light of the accumulated experience, prompted rediagnosis. All four lots are now believed to have tested negative, according to a personal communication from David Bodian. This finding, of course, should not be construed as justification of the 1954 practice but rather

as an explanation of why it did not lead to difficulties.)

Most of the modifications of this model which are required to make it more realistic are straightforward, but involved, and we shall not discuss them. There is one modification of possible interest that we mention here, however. We have justified the rule of estimating Y only from the 20 previously produced lots by considering the possibility that the level, m , fluctuates from lot to lot. The relation between P and Y was obtained on the assumption that it is constant, however. Does the relation between P and Y continue to hold when m is no longer assumed constant from lot to lot?

A perfectly general answer can be supplied. No matter how m fluctuates one can show

$$\bar{P} \leq 1 - \bar{Y}^{1/v} \quad [7]$$

where \bar{P} and \bar{Y} are averages of equations 4 and 5 over the appropriate distributions of m (see inset). The equality between P and Y pre-

Derivation of Equation 7

Define P and Y by equations 4 and 5; let m be the level of infection of a lot, and let v be the cubic centimeters tested of each lot. If now we suppose that m has an arbitrary distribution $F(m)$, we define \bar{Y} by

$$\bar{Y} = \int_0^1 e^{-m^v} dF(m) \quad [8]$$

and \bar{P} by

$$\begin{aligned} \bar{P} &= \frac{\int_0^1 (1 - e^{-m}) e^{-m^v} dF(m)}{\int_0^1 e^{-m^v} dF(m)} \\ &= 1 - \frac{\int_0^1 e^{-m^{v+1}} dF(m)}{\bar{Y}} \end{aligned} \quad [9]$$

From Liapounoff's inequality

$$\int_0^1 e^{-m^{v+1}} dF(m) \geq \left[\int_0^1 e^{-m^v} dF(m) \right]^{\frac{v+1}{v}} \quad [10]$$

Substituting from equation 10 in equation 9, equation 7 follows. A somewhat more general result has been obtained by Paul Meier in a study as yet unpublished.

question is possible because we do not know the infection level at which any given vaccine is produced. Suppose, for example, that all lots being produced by a manufacturer contain exactly one particulate per liter. Then no matter what the safety test, so long as any lots at all are passed, the outgoing lots will also contain one particulate per liter. In such a case, of course, a considerable proportion of batches submitted would fail the safety test, and it is unlikely that anyone, producer or tester, would feel any great confidence in the safety of the batches that passed. This example suggests that if one wishes to control the probability that an outgoing cubic centimeter contains live virus, one must consider not only the lot being tested but also the past history of testing, that is, the consistency with which safe lots have been produced. It also suggests a general way of proceeding.

Subject to the assumptions made earlier let us initially consider a manufacturer producing a single-strain pool at constant infection level m . Denote the probability that a cubic centimeter contains one or more particulates infectious for the test system by P . Then

$$P = 1 - e^{-m} \quad [4]$$

We shall henceforth refer to P as outgoing quality. Denote the probability that a batch produced at this level of infection will pass when v cc. are tested by Y . Then

$$Y = e^{-mv} \quad [5]$$

and

$$P = 1 - Y^{1/v} \quad [6]$$

For this simplest situation we thus have a relation between the probability that an outgoing cubic centimeter contains one or more particulates, P , and the proportion of lots, which pass, Y , for constant test level, v . P is a quantity that we wish to keep below some minimum level; the amount tested, v , is subject to our control; and Y , the proportion of lots passed, can be estimated from past experience. As it stands the model is too simple to be realistic, but solely in the interests of understanding its implications let us explore it numerically. Suppose we set P at some low level, say $5/100,000$ and consider $v=1,500$, that is, we consider the

entire testing process to consist of a single test of 4,500 cc. of the final trivalent pool. We then have

$$5 \times 10^{-5} = 1 - Y^{1/1500}$$

Solving, we obtain $Y=80.0$.

That is to say, if a manufacturer is producing lots at a constant but unknown level of contamination, and if 4,500 cc. of each batch are tested and 80.0 percent pass, then, given the assumptions previously made, it follows that out of every 100,000 cc. released, 5 would be expected to contain one or more live virus particulates.

If now under this model we wish to assure that the probability of live particulates in a cubic centimeter of passed vaccine never exceeds $5/100,000$, we pass a lot if, and only if: (a) the lot under consideration passes a safety test involving 4,500 cc.; and (b) at least 80.0 percent of previously tested lots have passed.

In practice we should, of course, wish to safeguard ourselves against a number of contingencies, perhaps the most important of which is that the level of m fluctuates from time to time. In that case one might wish to use only recent production information in estimating the value of Y for a producer. Suppose, for example, one looked at only the last 10 lots produced. If the probability of a negative were in fact constant and equal to .8, then the probability of passing all 10 is .11, which is rather high and suggests that a run of 10 negatives is not too improbable even for a Y less than .8. The probability of passing 20 out of 20 when $Y=.8$ is, however, .012, while the probability of failing 1 out of 20 is .058. One might thus regard 20 negatives out of 20 as evidence at approximately the .99 level of confidence that Y was at least equal to .8 and at least 1 positive out of 20 as evidence at this level that Y might be below .8. An amended procedure for providing that the probability of live particulates in a cubic centimeter from passed lots does not exceed $5/100,000$ would be to pass a lot if, and only if, it formed part of a run of 20 negative lots. More generally if we denote by n the size of the run of negative lots required, we have

$$n = \frac{\log \alpha}{v \log (1 - P)}$$

where $(1 - \alpha)$ is the level of confidence.

on the grounds that the increase would be more than counterbalanced by decreases in subsequent years.

It is even more difficult to indicate what factors should be considered in selecting a level of confidence. From a practical point of view, however, the value selected is not as crucial as that of P . Thus, increasing the level of confidence from .99 to .99999 increases the required length of negative runs by about two- and one-half-fold, whereas decreasing P from 5 to 1 per 100,000 increases it by fivefold. In general, the choice requires a compromise between the desire for a high degree of confidence and practical limitations on possible sizes of n .

It is important to realize that, after one has determined a value for outgoing quality, say $x/100,000$, and a confidence level, $1-\alpha$, it does not necessarily follow that in proportion α of the negative runs x cc. in every 100,000 will in fact contain live virus. What will actually happen depends on the safety of the production process. If the production process is safe, such levels will not occur. The logical structure of safety testing, in short, necessitates fixing a maximally tolerable level of outgoing infectivity, but this level need not necessarily ever be realized.

On the Assumptions Used

The key assumptions of the preceding section are that: (a) a vaccine can be considered as an idealized suspension of randomly and independently dispersed particulates, (b) the tissue culture and monkey tests used can be considered as an idealized test system capable of invariably detecting the presence of a single virus particulate, and (c) a child may be considered maximally sensitive and invariably capable of developing poliomyelitis, even when exposed to a single virus particle.

Several bits of evidence suggest that the last assumption is incorrect by several orders of magnitude. First of all, most persons have developed an immunity to the disease by the time they reach adult age even though not more than 1 percent have ever had clinically manifest poliomyelitis. Associated with this is an increased level of neutralizing antibodies (13), which suggests that most adults were at some

time in life infected by poliomyelitis virus without ever having developed the disease. More direct evidence on this point is provided by a longitudinal study of familial infection with poliomyelitis virus by Fox and associates (14). During a 3-year study of 156 households, they noted the development of 240 cases of infection with poliomyelitis virus as indicated either by the recovery of virus from stools or elevated serum antibody levels or both. There was not a single instance of paralytic disease in any of the 240 cases. Extrapolating these results to the community of which the households were considered to be a sample (for which community the incidence of paralytic poliomyelitis was known) they concluded that 1 paralytic case develops for every 710 cases of infection with poliomyelitis virus by the oral route.

Further suggestive evidence on this point has been brought to our attention by Nathanson and Hall. There were 105 cases of poliomyelitis among family contacts of Cutter vaccinated individuals. These may be presumed to have been infected by vaccinated family members. Only 1 of these 105 family members developed a case of the disease. Thus, on this premise, of 105 individuals sufficiently infected to pass the disease on to others 104 did not develop clinical poliomyelitis. The assumption that a child is maximally sensitive is thus a very conservative one. Testing procedures based upon this assumption will possess a considerable margin of safety, at least on this score.

Turning to the first two assumptions, we note that they imply that if one tests v cc. of a vaccine at infection level m , the probability of a positive result is from equation 3, $1 - e^{-mv}$.

This relationship between the probability of a positive result and amount tested, often referred to as the one-particle curve, is a well-known relationship in virology. It has been tested on a variety of plant and animal viruses and usually, although not invariably, found to apply (15). In principle, its applicability to the present problem could be tested by varying v in a vaccine preparation known to contain incompletely inactivated live virus. In practice, v can be varied only by diluting the vaccine, and the amount of live virus present in the vaccines tested has not been sufficient to give positive responses after dilution. To investigate

viously used now turns out to be an inequality and, fortunately, in the direction to make it useful. Thus, if 80.0 percent of a long series of lots, 4,500 cc. of each of which are tested, test negative, then the probability that a cubic centimeter of passed material contains one or more particulates is equal to or less than $5/100,000$. The assumption that m is constant is consequently the least favorable one for the safety tester, and the procedure suggested is one which protects him against the least favorable a priori distribution of m .

What are the factors that will influence the level at which P , the level of outgoing quality, is set? This is not a statistical question and consequently not one to which we can give an answer. It is, nevertheless, a question to which an answer is required, and it is worth indicating briefly some of the issues involved. First of all, P cannot be set at zero. That is to say, no amount of consistency testing can assure the complete absence of infectivity. The most that can be done is to keep P , the proportion of infected cubic centimeters, below some preassigned level. In selecting a numerical value for P , one must be guided by the consequences of the choice. The first major difficulty is that the consequence of introducing one virus particle into a human host is unknown. That is to say, if P is set at some value say $5/100,000$, and the production process is such that five 1-cc. inoculums in every 100,000 released do in fact contain one virus particulate, we are unable to say whether any of the five children receiving the infected inoculums would contract the disease. In the next section we shall consider more closely the relation between exposure to live virus particulates and the subsequent development of disease. Here we shall simply make the overly conservative assumption that all children exposed to one or more live virus particulates invariably develop the disease—that in setting a value of P we are also setting the incidence rate for poliomyelitis.

Now, the average annual incidence of paralytic poliomyelitis is very low. In the average epidemic year of 1954 it was about 50 per 100,000 persons in the age group 5-9 in areas covered by the field trial of the vaccine (9). The Francis report indicates that the 1954 field

trial vaccines reduced this rate by at least 50 percent, and epidemiological analysis of the 1955 experience leads to much the same conclusion (10). Thus, a value of P set at, say 50 percent of $50/100,000$ would not be safe enough since such a safety testing procedure could barely assure that passed vaccines would not cause more cases than they prevented.

The Cutter experience is illuminating. Approximately 400,000 children were inoculated with vaccines from 17 different filling lots produced by Cutter Laboratories. There were 61 cases of paralytic poliomyelitis among these children within 50 days of vaccination and an additional 97 among family or community contacts within 65 days. This amounts to an overall paralytic rate of 40 per 100,000 persons, most of which can be attributed to the vaccine. If we insist on setting P at 50 percent of $50/100,000$, then the level selected is approximately equal to the average Cutter level of infection. Undeniably this is not safe enough and P must be set well below $25/100,000$. How far below $25/100,000$ is suggested by the fact that Cutter vaccines were withdrawn from use not after 61 cases but after the first 6 cases out of 400,000 vaccinations.

One might of course argue that it is inappropriate to consider the annual incidence of poliomyelitis and that, in fact, a more appropriate magnitude is the lifetime probability of contracting the disease. This probability is a good deal higher, about 800 per 100,000 persons by age 24 according to a study of children of native white parents in 28 cities (11). Since this is 10 to 15 times the annual incidence, one might incline to a value of P well above $25/100,000$. There are several problems raised by this issue, however. First of all, if the risk of infection by the vaccine is to be balanced against the lifetime probability of developing the disease, then it is necessary that the vaccine confer lifetime immunity. Whether this is in fact the case is not now known and presumably will not be known for some time (see Salk (12), however). Second, and perhaps more fundamental, it is doubtful whether any community would (or should) tolerate safety standards that will permit the release of vaccines that raised the incidence of paralytic poliomyelitis in that year

hence on the choice between assumptions 2 and 2'.

In the literature of virology the parameter m is usually referred to as the number of elementary bodies and the parameter pm as the number of infectious units. The ratio of infectious units to elementary bodies has been determined for a number of virus-host systems. Two lines of evidence suggest that for the poliomyelitis virus its value in tissue culture may be well below unity and that assumption 2' rather than 2 is the appropriate one. The first is provided by electron microscope photographs of purified poliomyelitis virus preparations. From these it has been estimated that $p = \frac{1}{30}$ to $\frac{1}{60}$ (16). The second is provided by the results of intraspinal inoculation with infectious vaccine of monkeys rendered especially sensitive by pretreatment with cortisone. In a number of such experiments the dose required to infect the monkeys has been only a fraction of the dose required for tissue culture. Neither piece of evidence can at present be considered much more than suggestive. The results of the monkey experiments are as yet unpublished and require confirmation, while uncertainty as to the viability of the particles seen in the electron micrograph enjoins caution in interpretation. In the words of Dulbecco and Vogt (17) the relation between infectious units and elementary bodies "is still an open problem of highest interest." The mere fact that it is an open question does suggest, however, that a logical structure which is dependent upon the validity of assumption 2 may not be firmly grounded.

The first assumption, that a vaccine may be considered as an idealized suspension of randomly and independently dispersed particulates has also been questioned. Thus, Veldee has argued (18) that in the original virus suspension a significant proportion of virus particles are known to be imbedded in gelatinous protein material which cannot be removed by the finest filters. He suggests that formaldehyde may harden this material so that the imbedded virus particles cannot attach to the tissue cell in tissue culture. Growth of the virus in tissue culture is thereby prevented. Once the vaccine has been injected into a living animal, he goes on to suggest, enzymes present in the animal, but not in tissue culture, may free the virus particle of

its coating, after which growth may take place. No evidence that would either support or contradict this hypothesis is known to us.

If in the light of this discussion we reexamine the preceding section, it becomes apparent that the three assumptions listed at the beginning of the present section are sufficient but not necessary. The necessary assumptions are less limiting, namely, (a) the test system used is at least as sensitive to the presence of live virus as the human subject and (b) the probability of a negative response in tissue culture is a decreasing exponential function of test volume. The second assumption is supported by results of the type summarized in figure 3. The first is the crucial one and unfortunately the one about which only indirect evidence is ever likely to be available.

To cast some light on its possible validity, we consider the only evidence now available—the results of a cooperative study, undertaken immediately after the Cutter incident, of 16 of the 17 filling lots of vaccine produced by Cutter Laboratories. All 16 lots were tested in tissue culture, the total amount tested being somewhat less than 6 liters, or considerably less than is called for by present minimum requirements. Nine of the sixteen lots were also tested in 391 normal monkeys and 10 of the 16 in 178 intraspinally inoculated monkeys, which had been pretreated with cortisone. Of the 16 lots tested 6 were associated with an excess incidence of poliomyelitis (9). All 6 of these lots gave positive results, and, in addition, 2 of the lots that were not epidemiologically implicated also tested positive, 1 by tissue culture and 1 by cortisone treated monkey. These tests, which are not as extensive as those now called for by the minimum requirements, thus indicate that at least so far as the Cutter lots of the spring of 1955 are concerned the test system now used is as sensitive as and probably more sensitive than the human host. It would, of course, be desirable to have a good deal more information than can be extracted from that experience, but the results as far as they go are in the direction of validating the present testing program. Between the Cutter incident (and after the adoption of the new minimum requirements on May 26) and January 1, 1956, 37,500,000 cc. were released for public use without, so far as is

Figure 3. Tissue culture response during inactivation.

the question, we have consequently turned to data lying behind the inactivation curves previously discussed. The log titers on these curves are obtained by testing four successive tenfold dilutions. A volume of 0.5 cc. of the diluted suspension is introduced into each of 10 tissue culture bottles at each dilution and the presence or absence of viral growth noted. We show in figure 3 the results of one such run at four different inactivation times. The description of the relation between proportion of positive bottles and dose provided by the one-particle curve appears satisfactory, although a more searching examination would be possible if the spacing between dose levels were not so wide. A very large number of such comparisons is in fact possible, one for each single-strain lot of vaccine produced by each manufacturer. We have not investigated more than a fraction of them, but, for most of those that we have, the agreement between observation and hypothesis shown in the figure is by no means unusual.

Such agreement would appear to validate both the assumptions of an ideal suspension and of an ideal test system. This is too hasty a conclusion, however. Aside from the fact that no data are given for inactivation times beyond the third day, the assumption that one par-

ticulate will invariably initiate growth is sufficient but not necessary for the derivation of the one-particle curve. Thus, if we substitute for assumption 2 (p. 1048) the less limiting assumption:

2'. The probability that a virus particulate will initiate growth is constant for all tissue culture bottles and equal to p , and this probability does not depend on whether other particulates present have or have not initiated growth,

we also obtain the one-particle curve. Thus, the probability that a test batch of v cc. will contain z particles and that none of these will result in growth is

$$e^{-mv} \frac{(mv)^z}{z!} (1-p)^z \quad [11]$$

The probability of no growth is simply the sum of such terms over all values of z , and this sum is simply

$$e^{-pmv} \quad [12]$$

We can estimate the product pm from data such as that given in figure 3, but not p and m separately. In consequence the agreement between observed and theoretical in figure 3 provides no evidence on the numerical value of p and

Recent Studies in Surface Disinfection

By R. L. STEDMAN, Sc.D., and E. KRAVITZ, Sc.D.

ALTHOUGH many studies on disinfection have appeared in the literature during the past 75 years, significant and unexpected gaps in our knowledge of germicides remain. Efficiency in disinfecting floors, walls, and ceilings is one of the more significant gaps requiring detailed study. Until 1953, little information on the basic aspects of such disinfecting operations was available although Varley and Reddish (1) and Klarmann and associates (2) presented important but limited data.

For the past few years, the Department of the Navy has been conducting an extensive investigation of the problem at the Industrial Test Laboratory under the cognizance of the Bureau of Ships and Bureau of Medicine and Surgery. Because of the extent of the work, certain portions of this investigation were performed under contract at the Bacteriological Unit, Plant Pest Control Branch, Agricultural Research Service, Department of Agriculture, under the direction of Dr. L. S. Stuart. The salient findings obtained from these investigations to date and the results of certain other pertinent studies recently reported are reviewed in the current report.

When critically examined, disinfection of floors, walls, and ceilings represents a comparatively complex problem because of the many variables encountered in diverse disinfecting

operations. Such variables as the composition of the surface, the degrees of soil and microbial contamination, the type of micro-organisms present, the use of a washing procedure before disinfection, the degree of hardness of the water used in preparing the disinfectant dilutions, and many other factors represent a gamut of test conditions to be examined in a study of this nature.

Initially, it was obvious that not all of these conditions could be thoroughly investigated and that some compromise was required. Ultimately, it was decided to limit the study to floor disinfection by simulated use methods incorporating the various conditions described below.

Principal Test Methods

Two basic procedures for determining antimicrobial activity were developed for most of the work reported here (3-5). The first, the "Stuart" procedure, was used to measure the effect of precleaning on subsequent disinfection and consists of successively contaminating, cleaning, and disinfecting a large square of surface material. The pattern of elimination of micro-organisms is followed throughout the simulated precleaning and disinfection. The second, the "Square-Diluent" procedure, consists of contaminating and disinfecting 1-inch squares of surface materials in a manner that simulates actual conditions. This technique was used in all studies in which surfaces were not precleaned before disinfection.

The first technique gives a valid picture of the relative changes in antimicrobial numbers since a swab recovery technique is employed. The second method is of more value when the

known, being related to the development of any further cases. This is consistent with the conclusion suggested by the post-Cutter cooperative tests although it is of course hopelessly confounded with simultaneous improvements in the safety of the production process.

Summary

The safety of a vaccine will depend both upon the basic safety of the production process and the ability of safety testing procedures to detect an unsafe vaccine, if one is produced. Exclusive reliance upon the safety of a production process with a good past record, without the second line of defense provided by an adequate safety test, may be hazardous. Salk's early discussions of the nature of the inactivation process are reviewed, and his conclusion that safety was assured by the predictable nature of the inactivation process is critically appraised.

The major statistical problem in safety testing involves a decision as to how much testing is required. The procedures used in industrial quality control to solve this problem are not applicable to vaccine testing because the costs of erroneously rejecting good lots and of erroneously accepting bad ones are entirely incommensurable. An answer is derived instead by making certain statistical assumptions as to the dispersion of live virus in the vaccine, the sensitivity of the test system, and the viral concentration which is infective for man. The question of consistency testing is considered and a general theory derived for deciding how many successive lots of vaccine testing negative are required before a producer can be said to be a consistent producer of safe vaccine. Some of the questions that must be answered to apply this theory are considered. The assumptions on which this theory is based are critically analyzed.

nificance in the concept of disinfection but has been adequately treated elsewhere (6, 7).

Surface Porosity

Although the above generalization on the relative effectiveness of disinfectant types is valid, surface porosity tends to alter the quantitative pattern in certain instances (table 2). For example, certain phenolic formulations lose much more activity than others in changing from a nonporous to a porous surface (8).

Table 2. Effect of surface porosity in reducing antimicrobial efficiency of disinfectants

SOURCE: Reference 8.

The extent of this loss is apparently determined by the nature of the porous surface since significant differences in activity are observed on materials such as asphalt tile, battleship linoleum, soapstone, and wood. In most instances, chemical interaction between surface and germicidal agent is not observed and it seems valid to infer that porosity per se accounts in a large measure for these differences.

Superficial observation of the effective dilutions of germicides required for disinfection of the various porous surfaces (table 2) shows that impractically high concentrations are needed in many instances. Also, a different use-dilution of the same disinfectant may be

required for each porous surface. Obviously, it is not practical to employ such a multiplicity of use-dilutions with a disinfectant product. Some alternative procedure must be used to combine antimicrobial effectiveness and simplicity of operation.

Studies on this point have revealed that the effectiveness of the use-dilution recommended for a nonporous surface can be enhanced on a porous surface by the use of long exposure times and by successive treatments of the surface with germicide (9, 10).

As might be expected, the reduction of microbial numbers increases with length of exposure time and continues even after drying of the disinfectant is visibly completed. However, the time relationship is not linear, and after the first 10 minutes of exposure, the survivor curves tend to become asymptotic. For all practical purposes, the effective reduction in numbers is reached after the first 30 minutes.

Two successive applications of disinfectant are more effective than a single prolonged application in most instances, although the same pattern of initial rapid action followed by an asymptotic rate of reduction is encountered. With some disinfectants it appears that many successive applications on porous surfaces are required to achieve the same degree of effectiveness as attained on a nonporous surface such as stainless steel. At any rate, a significant increase in efficacy can be obtained by the use of long exposure times and successive germicidal applications, thus permitting a single use-dilution of disinfectant to be employed on a wide variety of surfaces.

Cumulative Effect

A daily routine program of applying disinfectants to floors produces an enhanced sanitary effect. Apparently, each successive daily application provides a prolonged residual of disinfectant which contributes to the antimicrobial efficiency of the next application (9). The degree of contribution is undoubtedly a function of the rate of evaporation, that is, vapor pressure, of the particular product since formulations vary rather widely in this respect. Ambient relative humidity is also of significance

absolute numbers of microbial survivors are required. Both techniques are versatile and permit the inclusion of many significant variables in actual disinfecting procedures.

Disinfectant Specificity

Obviously, the most useful disinfectants possess a minimum of antimicrobial specificity. In practical terms, this means that a disinfectant should be effective against a wide spectrum of microbial species when employed at a practical use-dilution. The particular specificities of some types of germicides have been known for some time, for example, the failure of unfortified pine oil formulations to be effective against pyogenic cocci. However, deficiencies in other types became apparent during the study. Table 1 presents representative data to illustrate this point.

On surfaces not precleaned, the quaternary ammonium germicides are effective under certain conditions. Substantial increases in the manufacturers' recommended concentrations of quaternaries are needed to achieve a high degree of bactericidal activity, but the new use-dilutions are not impractical to employ (table 1). However, these germicides are seriously deficient in antifungal activity, and require impractically strong concentrations in most instances.

The particular chlorine product tested was

much less effective against pyogenic cocci than against enteric bacilli and dermatophytic fungi (table 1). However, it cannot be stated at this time that chlorine products in general show this extreme specificity under conditions simulating floor disinfection because of the limited number of chlorine products tested. Also, it should be emphasized that such specificity may not be evident when the above or any chlorine product is employed as a sanitizer or water decontaminant; the environmental conditions in these instances, bacterial load, exposure time, physicochemical factors, and the like, are entirely different from those encountered in floor disinfection.

The synthetic phenolic and unfortified cresylic acids and coal tar products show less specificity than the other products. In most instances, the manufacturer's recommended use-dilutions are effective against the three test organisms. This is, perhaps, understandable, since the classical determination of use-dilution by extrapolation of laboratory data, that is, use-dilution in practice = $20 \times$ phenol coefficient obtained in a standard laboratory procedure, has been found to be more applicable to synthetic phenolics and related types than to quaternary ammonium germicides and halogens (6). However, discrepancies can readily be demonstrated even with the phenolics (7). This entire question of the correlation between phenol coefficient and recommended use-dilution is of sig-

stances, the handling of infectious matter without disinfectant protection during manipulation of swabs and buckets while precleaning may be a potentially hazardous operation. Also, the additional work of precleaning detracts from the simplicity of the operation. The presence of cleaner residues may deleteriously affect subsequent disinfection if an intermediate rinsing step is not employed. The inclusion of such a step adds still more complexity to the operation. Other disadvantages can be detailed. Nevertheless, it seemed of significance to study a number of phases involving precleaning.

The efficiency of mechanical removal of micro-organisms from surfaces by cleaners has been shown to be a function of the porosity of the test surface. Flannery and associates (3) observed that, using standard Navy soap powder, dried white oak was more difficult to decontaminate than soapstone; stainless steel was most easily decontaminated of the three surfaces studied. No significant difference was found when four different types of cleaners, white floating soap, a non-ionic detergent, trisodium phosphate, and Navy soap powder, were tested under comparable conditions on a white oak surface.

Surprisingly large numbers of organisms

were shown to resist removal by mechanical cleaning. For example, after six successive washings of an artificially contaminated porous oak surface, approximately 2-6 percent of the original number of organisms still remained on the wood. Assuming an initial arbitrary load of 2,000,000 organisms per square inch, a relatively large number, 40,000-120,000, would still be present after precleaning in such cases. Although decontamination of stainless steel was more easily accomplished (99.90-99.98 percent of original cell numbers removed by two washings), small numbers of organisms could still be recovered from the nonporous surface even after six consecutive washings. The concentration of the cleaner affected the efficiency of removal in some instances, but the differences were not striking.

Evidently, mechanical removal of micro-organisms by precleaning does not obviate the need for a very efficient disinfectant. Further data on this point are shown in table 4. An artificially contaminated soapstone surface was precleaned (one wash) with trisodium phosphate and then disinfected with various levels of sodium hypochlorite or the quaternary ammonium germicide, alkyl (C_8H_{17} - $C_{18}H_{37}$) dimethyl benzyl ammonium chloride (3). In no case was complete elimination of all test or-

⁴ These products gave identical results in the indicated tests.

in this regard (11, 12). With many disinfectants the residual is sufficient to kill small numbers of organisms without the aid of additional disinfectant after contamination (2, 9, 11). Such an effect may be of importance in the elimination of dustborne hemolytic streptococci and other organisms in hospital wards, dispensaries, and the like.

Formulation Properties

As noted above, disinfectant formulations, even of the same chemical type, vary widely in the degree of antimicrobial activity retained on a nonporous as compared to a porous surface.

These variations in retention of activity have been shown to be due, at least in part, to differences in certain physicochemical properties of formulations (13): surface tension depression, spreading wetting and detergency. Although a quantitative correlation between retention of activity and any of these properties could not be demonstrated, some relationship was noted (table 3).

Products with poor or excellent retention were found to possess relatively poor or excellent efficiencies in the physicochemical proper-

ties. This relationship is, perhaps, not unexpected since surface tension depression, wetting, detergency, suspending power, emulsification, and other similar properties contribute in various degrees to the penetration and cleansing of porous surfaces. Superior penetration and disinfection of the crevices and pores of surfaces such as battleship linoleum or asphalt tile would be anticipated with a product outstanding in the above physicochemical properties. Undoubtedly, the failure to establish a concise correlation shows a complex interrelation of the many physicochemical properties which contribute to disinfection.

Ortenzio and associates (13) have also emphasized the importance of the physicochemical properties of formulations in disinfection. A graphic demonstration of the enhancement of disinfectant efficiency was shown by the addition of small amounts of cleaners and sequestering agents to various types of disinfectant use-dilutions. The enhancement was believed to have resulted from an improvement in the soil suspending and dispersing properties of the solution. The authors concluded that consideration should be given to requiring certain standards for soil suspending and dispersing properties of disinfectants when a combined cleaning and disinfecting action is claimed on the label.

Unfortunately, many commonly employed laboratory methods for determining disinfectant activity present an array of physicochemical factors which bear little or no relationship to those encountered when the disinfectant is used in practice, although a tendency has been noted more recently to employ simulated use procedures. Further effort should be devoted to a study of such procedures and to the development of formulations having physicochemical properties which enhance antimicrobial effectiveness in use.

Precleaning

On superficial examination, it might be expected that precleaning of a contaminated surface prior to disinfection would produce a much more effective process than disinfection without precleaning. However, there are certain obvious objections to such a process. In some in-

posited on wax-coated surfaces in simulated-sneezing experiments (15). Probably, moisture is required for a lethal action to occur, as in the case of all known antimicrobial agents, and ambient relative humidity may play a significant role.

The degree of effectiveness may be equivalent at best to that of disinfectant residues remaining on surfaces as a result of a routine daily treatment, but significant elimination of gross contamination deposited on surfaces coated with germicidal waxes without further addition of a disinfectant seems distinctly improbable. The exact role of these agents in environmental sanitation must await further study.

Summary and Conclusions

The salient points obtained in an extensive investigation of floor disinfection conducted by the Department of the Navy have been presented. The implications of other current findings in the literature have also been integrated and presented.

Using test procedures that attempt to simulate use conditions, investigators determined that the degree of efficiency of disinfectants used on floors is influenced markedly by the porosity of the floor surface. Certain representative chemical types of disinfectants were shown to be deficient in antimicrobial activity particularly in regard to species specificity. With synthetic phenolic formulations, the efficiency of disinfection of porous surfaces is related significantly to the physicochemical properties of the formulation. However, by long exposure times or by successive treatments with germicide, a significant reduction in microbial numbers on a porous surface can be achieved. Waxing of porous surfaces apparently does not alter strikingly the efficiency of disinfection attained on the unwaxed surface. A daily routine of disinfection contributes significantly to the ease with which porous surfaces can be decontaminated.

Studies on the effect of precleaning surfaces before disinfection have shown that the efficiency of the cleaning operation is also intimately related to surface porosity. Unfortunately, the contribution of precleaning to the

disinfecting process is greatest on nonporous surfaces which are, in themselves, relatively easy to decontaminate by a single application of germicide. The types of cleaner and disinfectant employed must be carefully chosen since residuals of cleaner remaining may seriously inactivate the germicide if the two are incompatible.

ganisms achieved with one application of either germicide up to concentrations of 1,000 p.p.m. after precleaning. Antimicrobial effects were initially observed at 200 p.p.m. halogen and 1,000 p.p.m. quaternary.

It was concluded: "The concentrations of germicides necessary to produce disinfection of soiled surfaces after cleaning by a swab-washing procedure (with the exception of highly polished surfaces such as stainless steel) appear to be from three to five times as great as those commonly accepted for use as final germicidal rinses for dishes and glasses in restaurants, and utensils and equipment in dairies and food plants."

The latter portion of this quotation is of significance in that hypochlorites and quaternaries are used primarily as sanitizing agents, and it was desired to relate in some fashion recommended sanitizing use-dilutions with effective disinfecting operations.

In general, the data in tables 2 and 4 (3, 8-10) indicate that the porosity of the test surface is of prime importance in deciding the effectiveness of a precleaning operation in reducing the load on the disinfectant subsequently employed. Porous surfaces can be more easily decontaminated when precleaned, but relatively strong concentrations of germicide are still required in the subsequent disinfecting operation. Unfortunately, precleaning appears to be most effective under conditions in which disinfection alone can be readily accomplished, that is, on a nonporous surface. It is questionable whether precleaning is worth the effort under such conditions, assuming that an effective disinfectant at proper concentration is ultimately employed.

Effect of Cleaner Residues

As noted above, residues from precleaning procedures may affect deleteriously subsequent disinfection if such residues are not thoroughly removed by rinsing. Ortenzio and co-workers (14) have demonstrated the extent of this inactivation using quaternary ammonium and phenolic disinfectants.

As expected, the chemical nature of the cleaner determines the extent of inactivation. Soaps are more deleterious to quaternaries than phenolics, and the reverse is true for non-ionic

detergent cleaners. When the cleaner and disinfectant are "incompatible," as much as 2.5 times more disinfectant is needed to produce the same antimicrobial effect as in the case of a "compatible" combination. Even alkaline inorganic cleaners, such as trisodium phosphate and sodium carbonate, may seriously inactivate quaternary ammonium disinfectants if soil containing fat is present, presumably due to formation of traces of soap.

It is apparent that an effective precleaning procedure, if employed, must be discriminately chosen and be properly performed.

Waxing

Since the practice of waxing surfaces is widespread in civilian and military establishments where pathogenic micro-organisms may be of significance, the effect of such a practice on subsequent disinfection has been determined (9). Surprisingly, the antimicrobial effectiveness of disinfectants on a waxed linoleum surface was not found to be strikingly different from an unwaxed surface. This was attributed to the failure of the wax to form a microscopically smooth outer layer and, in effect, transform the porous linoleum surface into a nonporous one. The waxed surface was significantly scratched and pitted after the waxing operation, presumably, because of the action of the buffing machine and solvent evaporation. For all practical purposes, the waxed surface was still porous.

Quite recently, "germicidal" floor waxes have been placed on the market. Such products consist of self-polishing water emulsion waxes with germicidal agents added (15). Present formulations list either a quaternary ammonium or a phenolic disinfectant as the biologically active ingredient. Possibly, these products act physically in a manner similar to "insecticidal" waxes which have been in use for a number of years: The biologically active material slowly leaches to the surface of the wax and provides an insecticidal or germicidal outer layer.

Since only preliminary data are available on the efficacy of germicidal floor waxes, a definitive conclusion on their usefulness cannot be made at present. However, it has been shown that these formulations are capable of eliminating small numbers of organisms which are de-

A Scientific Approach to Fetal Wastage In Halifax County, North Carolina

By ROBERT F. YOUNG, M.D., M.P.H.

HALIFAX COUNTY, a rural county in eastern North Carolina, had reason to search for the causes of its high infant mortality rates. The 1952 rate had soared to an all-time high of 72.9 per 1,000 live births. Neonatal and premature death rates had climbed to 42.7 and 21.4 in 1952. Prematurity was the second leading cause of death that same year, outranking cancer and accidents.

Halifax County's population of 60,000 is 58 percent Negro. The birth rate for Negroes in 1952 was 35.2 as compared with 21.5 for white residents. Only 36.2 percent of all deliveries, white and nonwhite, occurred in hospitals. The county has 25 private physicians and 2 hospitals. There are 2 hospitals in the adjacent counties also.

Midwives were called in to attend 79.9 percent of all Negro home deliveries. Patients for midwife delivery are required to be certified either by a physician in private practice or by a clinician in charge of one of the 4 prenatal clinics operated by the county health department. The midwives are licensed by and work under the direct supervision of the health department.

Dr. Young, honored in 1950 with the Reynolds award for outstanding public health performance, is director of the Halifax County (N. C.) Health Department. He has been president of the Halifax County Medical Society and more recently president of the North Carolina Public Health Association, president of the North Carolina Academy of Public Health and Preventive Medicine, and secretary-treasurer of the North Carolina Trudeau Society.

Representatives of the North Carolina State Board of Health, University of North Carolina School of Public Health, North Carolina Medical Society, Halifax County Medical Society, and the Children's Bureau of the Department of Health, Education, and Welfare joined forces with the Halifax County Health Department in seeking answers to that vexing question, "Why does immature as well as defective fruit fall from the tree of life?"

An ambitious and well-designed research project on infant mortality tailored for Halifax County and neighboring counties with high rates failed to obtain supporting funds. The county health department and the allied groups persisted in exploring ways of using available facilities and local personnel in a demonstration program that might favorably influence infant mortality and morbidity rates. During these studies and conferences, three factors seemed to occur again and again:

- The plans for demonstration programs were lacking in adequate analysis and application of pertinent data.
- The diets of prenatal clinic patients were markedly deficient in protein and in other nutrients.
- Certain of these women habitually produced fetal deaths, premature infants, or babies who failed to survive the neonatal period.

Pinpointing the Problem

With the help of statistics and health education consultants, our public health nurses and secretaries undertook to remedy the deficiency in statistical data by preparing accurate tabula-

- orthophenylphenol. *J. Infect. Dis.* 96:40-53, January-February 1955.

Shellfish Sanitation Workshop

A Shellfish Sanitation Workshop, held in Washington August 27 and 28, 1956, had a registered attendance of 58. Fourteen States were represented by 18 persons. The oyster industry was represented by 6 persons designated by the Oyster Institute of North America and by 2 representatives from the National Fisheries Institute. The Canadian Government had two representatives (Department of National Health and Welfare, and Department of Fisheries). Other agencies or organizations with representatives present included the Public Health Service, Departments of Army, Navy, and Air Force, Food and Drug Administration, Fish and Wildlife Service, American Cyanamid Co., and the University of Maryland. The Association of State and Territorial Health Officers was represented by Dr. Mack I. Shanholtz of Virginia.

The manual of recommended practice for sanitary control of the shellfish industry, as revised at the meeting, was unanimously adopted by the workshop for use as a guide in the cooperative shellfish certification program.

On the basis of studies made by the Canadian Department of National Health and Welfare, the Maryland Department of Health, the Virginia Department of Health, and the Public Health Service Shellfish Sanitation Laboratory, a 1-year interim

bacteriological market standard was adopted for shucked oysters. This interim standard is the first of its kind in the 31-year history of the shellfish program and establishes three categories of evaluation:

Category	Coliform MPN	Standard plate count
Acceptable.....	Not more than 16,000 per 100 ml.	Not more than 50,000 per ml.
Acceptable on condition. ¹	Less than 160,000 per 100 ml.	Less than 1,000,000 per ml.
Rejectable.....	160,000 or more per 100 ml.	1,000,000 or more per ml.

¹ Shipments will be reported to the shellfish control organization of the originating State for investigation and will not be rejected unless the report of the investigating authority is unsatisfactory.

The workshop also considered effects of the dis-Public Health Service to undertake an investigation of organisms other than coliforms as indicators of the sanitary quality of shellfish.

The workshop also considered effects of the disposal of wastes from cabin cruisers and other shipping. Harold F. Udell, New York State Department of Conservation, estimated there were approximately 15 to 16 thousand pleasure craft equipped with toilet facilities and registered in the Marine District of the State of New York.

A Scientific Approach to Fetal Wastage In Halifax County, North Carolina

By ROBERT F. YOUNG, M.D., M.P.H.

HALIFAX COUNTY, a rural county in eastern North Carolina, had reason to search for the causes of its high infant mortality rates. The 1952 rate had soared to an all-time high of 72.9 per 1,000 live births. Neonatal and premature death rates had climbed to 42.7 and 21.4 in 1952. Prematurity was the second leading cause of death that same year, outranking cancer and accidents.

Halifax County's population of 60,000 is 58 percent Negro. The birth rate for Negroes in 1952 was 35.2 as compared with 21.5 for white residents. Only 36.2 percent of all deliveries, white and nonwhite, occurred in hospitals. The county has 25 private physicians and 2 hospitals. There are 2 hospitals in the adjacent counties also.

Midwives were called in to attend 79.9 percent of all Negro home deliveries. Patients for midwife delivery are required to be certified either by a physician in private practice or by a clinician in charge of one of the 4 prenatal clinics operated by the county health department. The midwives are licensed by and work under the direct supervision of the health department.

Dr. Young, honored in 1950 with the Reynolds award for outstanding public health performance, is director of the Halifax County (N. C.) Health Department. He has been president of the Halifax County Medical Society and more recently president of the North Carolina Public Health Association, president of the North Carolina Academy of Public Health and Preventive Medicine, and secretary-treasurer of the North Carolina Trudeau Society.

Representatives of the North Carolina State Board of Health, University of North Carolina School of Public Health, North Carolina Medical Society, Halifax County Medical Society, and the Children's Bureau of the Department of Health, Education, and Welfare joined forces with the Halifax County Health Department in seeking answers to that vexing question, "Why does immature as well as defective fruit fall from the tree of life?"

An ambitious and well-designed research project on infant mortality tailored for Halifax County and neighboring counties with high rates failed to obtain supporting funds. The county health department and the allied groups persisted in exploring ways of using available facilities and local personnel in a demonstration program that might favorably influence infant mortality and morbidity rates. During these studies and conferences, three factors seemed to occur again and again:

- The plans for demonstration programs were lacking in adequate analysis and application of pertinent data.
- The diets of prenatal clinic patients were markedly deficient in protein and in other nutrients.
- Certain of these women habitually produced fetal deaths, premature infants, or babies who failed to survive the neonatal period.

Pinpointing the Problem

With the help of statistics and health education consultants, our public health nurses and secretaries undertook to remedy the deficiency in statistical data by preparing accurate tabula-

tions of infant, neonatal, fetal, premature, and maternal deaths, by race, for the 5-year period 1947-51. These statistics, though available in the health department, had not been assembled for maximum effectiveness.

Next, they collected and assembled pertinent details on exact geographic location of the patient's home, cause of the infant or maternal death, type of attendant (whether physician or midwife), and the place of delivery (whether in the hospital or at home). They also compiled complete details about the weight, period of gestation, attendant, place, and date of delivery of premature births. Because an epidemic of infectious diarrhea in one section of the county in 1952 had contributed to the high infant death rate, they made a special study of infant deaths from infectious diarrhea, analyzing the records in a local hospital that had been particularly affected.

After all information had been checked for accuracy with the vital statistics section of the State health department, the consultants were called in to recommend the best way of presenting the material to the health department staff, professional groups in the county, and key civic and voluntary organizations. They agreed that our presentation should be a combination of tables, graphs, and large county maps on which premature births and other associated infant mortality data would be plotted by the public health nurses.

Flip charts were prepared from semitransparent tracing paper. Separate sheets of each 48"×34" chart were superimposed over a basic map of Halifax County, showing the general outline of townships and local divisions.

It was apparent from the presentation material that most of the infant deaths had occurred in three distinct areas of the county. This epidemiological observation led us to set up a prenatal demonstration clinic in each area.

Concentrating on Diet

Attention was next directed to the nutrition of prenatal patients. Careful review of their clinic records over a 3-year period revealed that the great majority of these patients drank no milk or at best an insufficient amount. Other protein foods in their diets during pregnancy were also inadequate.

Public health studies have documented the fact that low protein diets among prenatal patients are partly responsible for high maternal, infant, and related mortality and morbidity rates. These observations were emphasized at the 1955 meeting of the American Public Health Association, when Dr. August R. Lindt, the permanent observer of Switzerland to the United Nations, reviewed the benefits of surplus milk for prenatal patients and children in 45 different countries before the National Citizens Committee of the World Health Organization.

To aid study of the nutrition factor in local infant mortality, consultants in obstetrics and nutrition helped us design a special record for appraising the characteristics of the diet of prenatal patients. Because of the large number of new cases admitted to the demonstration clinics and the limited number of personnel, the record had to be simple in form yet adequate for the desired information.

For evaluation of each patient's diet, public health nurses record the food consumed at the three meals preceding the clinic visit as well as the food eaten between meals and at bedtime. This information is entered under separate sections for "breakfast" and "between," "lunch" and "between," "supper" and "bedtime" in a column of the diet record headed "food and amounts." The food items are coded in a second column and scored in a third.

The diet is rated "good" (9-10 points), "fair" (7-9 points), and "poor" (below 7 points) according to the following guide.

Code	Food and amount	Possible score
F & V----	Fruit and vegetables----- ½ cup fruits, vegetables, or juice=1 point	4
M-----	Milk----- 1 cup=1 point 2 cups=2 points 3-4 cups=3 points	3
P-----	Protein food----- 2 servings of 3 oz. lean meat or equivalent	2
B-----	Bread and cereals----- 2 servings	1
	Perfect score-----	10

As soon as these records were completed, the nutrition consultants began holding inservice training sessions for nurses, 2 hours each week

over a period of 6 weeks. Training in nutrition included a careful study of the diet records and diet histories of the demonstration patients; instruction in nutrients, food portions, and food values; and methods of teaching food values to clinic patients.

Knowing that surplus nonfat dry milk was available to public schools and other public institutions in the county, we explored the possibility of obtaining this important protein food for the prenatal patients whose diets were deficient in protein. The surplus commodity food section of the State department of agriculture approved our proposal for issuing free milk to medically indigent patients in the demonstration clinics, and the county welfare department certified their eligibility.

A patient who receives an allotment of 9 pounds of dry milk every 30 days during her pregnancy is provided with the equivalent of 1 quart of fluid milk a day. Clinic classes and individual conferences are held to show prenatal patients how to use dry milk for drinking and cooking. They learn, too, about other protein foods that are locally available.

An inventory showing the amount of milk received and distributed each month is kept for the department of agriculture. Other records include a form on which patients acknowledge receipt of the milk and agree to its use as prescribed by the clinic and a form on which public health nurses determine medical indigency.

During the first 6 months of the demonstration program, a public health nurse visited the patients participating in the milk distribution to assure that dry milk was being used in accordance with the clinic's instructions. (Home visits for this purpose have since become a part of the generalized public health nursing program.) Throughout the country, home economics teachers, home demonstration agents, and 4-H club leaders were alerted to the objectives of the surplus milk program so that they also could emphasize the importance of protein foods in prenatal diets.

Finding the Problem Patients

The third factor in our initial studies had repeated itself with stubborn regularity: Certain women attending the clinics seemed to produce

more than their share of infant deaths and related morbidity and mortality. To find the problem cases on which to concentrate preventive efforts, we designed a screening device that combined a maternity record and a score sheet on which to grade the pregnancy risk of the mother and the survival risk of the fetus.

Maternity Record

The maternity record is still undergoing trial in the prenatal clinics. It is designed so that grades of "good," "fair," or "poor" risk are given in each of seven major sections: (a) mother's previous obstetrical history, (b) her previous medical history, (c) the family history, (d) the mother's diet, (e) physical examination (including pelvic evaluation), (f) laboratory and X-ray findings, and (g) subsequent antepartum visits. The total risk for each patient is based on the grades in each of these respective sections.

At the close of each clinic session, nurses review and grade each patient on the major sections of the record. Patients graded "fair" or "poor" are selected for more frequent visits to the prenatal clinics and for intensive followup through home visits by the nurses.

The following outlines from two sections of the trial maternity record illustrate the grading system.

Previous Obstetrical History. A grade of "good" is given to the patient whose previous obstetrical history is essentially negative. A grade of "fair" is based on any one or a combination of the following factors:

1. Seven or more deliveries.
2. One abortion.
3. A history of any single complication other than toxemia; for example, hemorrhage (antepartum) or mild hypertension.
4. One premature child living or dead, 1 fetal death, or 1 infant death.

A grade of "poor" is based on any one or a combination of the following criteria:

1. Cesarean section.
2. Two or more abortions.
3. History of toxemia.
4. History of 2 or more other complications.
5. Two or more premature children living or dead, 2 or more fetal deaths, or 2 or more infant deaths.

6. A combination of 2 or more abortions, premature births, fetal deaths, or infant deaths.

Physical Examination. A grade of "good" is given to the patient in good general condition with essentially negative findings on her physical examination. A grade of "fair" is given when the physical examination reveals the following conditions:

1. More than 20 percent overweight.
2. Blood pressure 140/90 or above.
3. Edema of the feet.
4. Inactive tuberclosis.
5. Any other condition or combination of conditions that, in the examining physician's judgment, would grade the patient's physical condition as fair.

A grade of "poor" is justified when these conditions are present:

1. A combination of elevated blood pressure, increased weight, and edema.
2. Hypertension 150/100 or above.
3. Active pulmonary tuberculosis or syphilis.
4. Edema of the feet and hands, or edema of the face, or both.
5. Organic heart disease.
6. Marked deformity of the spine.
7. Breech presentation.
8. Serious change in the fetal heart rate such as inability to hear the fetal heart sounds.
9. Contracted pelvis or any other serious deficiency in the pelvic measurements.
10. Any other condition or combination of conditions that, in the examining physician's judgment, would grade the patient's physical condition as poor.

Grade of Risk

The final calculation of the grade of risk for each patient is based on these criteria for "good," "fair," and "poor." It must be emphasized that the grading is influenced by local conditions.

Good. A patient whose maternity record is essentially negative in all seven sections is graded a good risk.

Fair. Grades of "fair" for the sections on previous obstetrical history and physical examination or the section on laboratory and X-ray findings would automatically grade the patient as a fair risk. A grade of "fair" in two or more of the remaining sections, namely, pre-

vious medical history, family history, and diet, would give the patient a grade of risk of "fair."

Poor. A grade of "poor" for the section on previous obstetrical history and the section on physical examination or the section on laboratory and X-ray findings would automatically give the patient a grade of risk of "poor." A rating of "poor" in two or more of the other sections would give the patient a grade of "poor."

A sudden increase in weight or blood pressure, the appearance of significant edema, bleeding, any other significant findings, or a combination of conditions might warrant, of course, a change in the grade of risk under the section on antepartum visits.

Although from a first glance the grading system might appear cumbersome and complicated, I hasten to add that, after a relatively short period of working with the record, nurses and clinicians are able to evaluate the patients with speed and accuracy. The record serves not only to select patients of special risk but also to emphasize to our clinic personnel those factors which are of major significance in the prognosis of the prenatal patient.

Evidence of Decline

My purpose has been to review a purely local approach to a specific local public health program. I have attempted to suggest that even when outside help is not available on a grand scale and the local resources and facilities are limited there is still a great deal that can be accomplished by applying the fundamental tools of public health.

Although there has been a decline in pertinent rates, we feel that the program should be continued for a longer period of time before attempting an analysis of these data.

Lest I may have given the impression that Halifax County's approach to the problem of fetal wastage is a final solution, I wish to emphasize that our experience underlines the need for more intensive investigation of the unknown factors.

Samples of the forms described are available from the Halifax County Health Department.

Legislation on Air Pollution

By FREDERICK S. MALLETT

THERE IS considerable evidence to show that today the forms and degrees of air pollution are demonstrably worse than ever in human history. The causes of this increase in pollution are, briefly: the tremendous growth of population in our cities, owing to both migration and birth rate; the enormous increase in numbers of automobiles, trucks, and buses and their associated exhaust gases; the incineration of vast volumes of rubbish; the combustion, both domestic and industrial, of megatons of fuels; and the great expansion of manufacturing processes of all kinds, resulting in new and, as yet, uncontrolled effluents.

The atmospheric sewer is backing up and, like a swarming bacterial colony, we are beginning to suffer from the accumulation of our own wastes.

To control the atmospheric byproducts of modern civilization, we have turned to a good old-fashioned remedy, the law. We are trying, at the moment, to legislate air pollution out

of existence. The solution to the problem is not quite so simple.

Modern Legislation

Most early laws and ordinances dealt with smoke only; fly ash or soot appeared in the picture somewhat later. In this country, the earliest recognized instance occurred not quite 100 years ago, when an 1864 lawsuit in St. Louis resulted in a judgment declaring smoke to be a nuisance. This action was followed 3 years later by adoption of an ordinance requiring that the chimneys of all manufacturing establishments be at least 20 feet above the adjoining buildings.

Chicago adopted its first smoke ordinance in 1881. This provided that the emission of dense smoke "shall be a public nuisance." No definition of smoke or of its density was given.

A 1912 survey by the United States Bureau of Mines found that 12 cities with a population of less than 50,000 had either a smoke ordinance or a smoke inspector and that about 19 cities of 50,000-200,000 were active in the suppression of smoke. Of the 28 cities with more than 200,000 population, 23 showed activity.

Contra Costa County, Calif., in 1915, adopted an ordinance restricting "fume" strength as an outgrowth of the Selby smelter problem. However, the first countywide legislation and enforcement appeared in Hudson County, N. J., in 1931.

The first State legislation appeared in 1909 in Rhode Island, covering smoke emission in cities over 150,000 population. Domestic

Mr. Mallett is a consultant on air pollution problems and is also executive secretary of the Committee on Air Pollution Controls, the American Society of Mechanical Engineers. He formerly was associated with the Public Health Service Occupational Morbidity and Mortality Study, 1935-37, Detroit. Mr. Mallett's original paper, which was somewhat longer, was presented before the 18th annual meeting of the American Power Conference, sponsored by the Illinois Institute of Technology and held at Chicago, March 21-23, 1956.

sources were exempted, as were locomotives at the time of starting and feeding fires while in roundhouses or yards.

Massachusetts, in 1910, introduced in its smoke control law a device for estimating smoke density which is still extant, namely, the Ringelmann chart. The chart was devised in the 1880's by a French professor of agricultural engineering and was first used in this country in 1899. With all its shortcomings, it is still widely used although several other devices have been introduced. The model ordinance published by the American Society of Mechanical Engineers, which has formed the basis for most municipal smoke abatement ordinances in this country, includes the Ringelmann chart.

For a number of years, New Jersey and metropolitan New York have been disturbed by interstate air pollution. Bills were introduced in the legislatures of both New Jersey and New York to institute an interstate survey, but until 1955, when New Jersey finally passed a matching bill, these had been passed only by New York. The New Jersey bill provided for an investigation of the area in question to determine whether an interstate air pollution problem exists and, if so, to recommend appropriate controls, an agency to apply them, and to suggest the draft of legislation necessary to implement the findings.

The Interstate Sanitation Commission was directed to undertake the study, for which New York and New Jersey each provided \$30,000. The terminal date for the presentation of findings and recommendations was set for February 1956. However, the investigation has been delayed because of legal complications over jurisdiction.

A joint resolution by both houses of the Congress signed August 3, 1956, by the President, approves the present bi-State arrangement in which the State of Connecticut, the third member of the Interstate Sanitation Commission, has acquiesced. Bills have been passed by both the New York Legislature and the New Jersey Assembly, updating and approving the commission's plans for proceeding.

Both Canada and the United States have shared concern over air pollution in two areas: one at Trail, B. C., from 1928 to 1935, and the other at Detroit, Mich., and Windsor, Ont., since

1950. The International Joint Commission undertook the Detroit-Windsor investigation, which originally was concerned with smoke from the vessels traversing the Detroit River. This joint interest in smoke control has been expanded into a comprehensive study to determine the effect of air pollution on almost every aspect of community life.

Local Accomplishments

St. Louis was probably the first large city to make an effective reduction in smoke pollution. Before 1940, particularly in the winter, dense smogs were frequent occurrences. It was not uncommon there to have lights and headlights burning until noon. Now there is acceptable evidence to prove that a marked reduction in smoke pollution has been brought about by the city.

Essentially, this improvement was achieved through enactment and enforcement of an ordinance prohibiting the sale of high volatile coal in the city except in sizes under 2 inches. It was also required that all bituminous coal containing over 12 percent ash or 2 percent sulfur be washed.

Allegheny County

For many years, efforts at smoke control in Pittsburgh had such little success that the place was widely known as the "Smoky City." Residents of Pittsburgh can truly testify to the density and irritating qualities of the "black days." Until the late 1940's, Pittsburgh was deteriorating in every way, but finally a great civic movement—the Allegheny Conference on Community Development—arose to resuscitate the decaying city. It was the force behind this great effort which brought about the change in the Pittsburgh atmosphere.

The details of the city of Pittsburgh and Allegheny County ordinances are too complex for a brief discussion. Based in large part upon the St. Louis ordinance, these ordinances brought about a marked reduction in the smoke content of the air, principally by increased inspection and enforcement and by restricting the volatile content of solid fuels. It should not be assumed, however, that a miracle has occurred and that there is no pollution left to be con-

trolled in Pittsburgh and Allegheny County: quite the contrary. Nevertheless, a truly remarkable improvement has been achieved. There are many technical problems left to solve, but, at least, attention is being given them. Under study are effective and economical control methods—especially for steel processes—which may replace conventional and costly equipment presently available.

Los Angeles County

Los Angeles' smog began to appear as a serious problem during the industrial expansion and population growth of the World War II period. More than \$1 billion in new capital was invested from 1941 to 1950, and more than 5 million people were added to the population of Los Angeles County. People began to be aware of an irritation of the eyes and respiratory tract. This smarting of the membranes and lachrymation were associated with the presence of a noticeable haze. Two other features of the smog, whose relationship was not learned until later, were damage to vegetation, especially certain truck garden crops, and accelerated cracking of rubber, most noticeable in the sidewalls of tires.

Insistent public demand brought about the passage, in 1947, of a State enabling act which created control districts to be activated by any county that determined control to be necessary. At least 4 California counties have active districts, and several other districts have been authorized; there is one authorized 9-county group in which 6 counties are organizing.

The California State enabling act specifically and generally prohibits air pollution and provides for the establishment of local rules and regulations by each control district. Those of the Los Angeles Air Pollution Control District provide a permit system for both construction and operation of any equipment which may cause emission of air contaminants. Detailed plans and specifications must be filed before permits are granted for new construction or modernization. Under these provisions the district engineers have approved permits for well over \$100 million, of which over 15 percent is for control equipment. The rules also apply restrictions for specific pollutants such as

particulate matter, sulfur gases, and the solid products of combustion in excess of certain concentrations.

The Los Angeles County Air Pollution Control District, the enforcing body, has had a harried history. Although smog may occur during any month of the year, it is most prevalent during the late summer and the autumn and may even extend through December into January, as it did in 1953. In 1954, a 17-consecutive-day episode occurred during which public protest became uproarious. The board of county supervisors—the governing body—reorganized the agencies, providing for enforcement by strenuous prosecution. So many violations were cited that a special smog court was set up. However, in spite of the vigorous enforcement effort, on September 13, 1955, the worst smog ever recorded occurred. The lesson to be learned from the situation is that the problem of urban air pollution should be tackled in its potential state rather than when it becomes an actual and serious problem.

Other California Developments

Two events in southern California are noteworthy. The first is the use of the Ringelmann chart to judge the opacity of plumes composed of other than black smoke, the original purpose for which the chart was devised. The other is the refusal of an operating permit for a steam power station because, among other reasons, of the high sulfur content of the fuel which it proposed to use.

Early in 1955, local courts affirmed violations of the opacity sections of the Los Angeles regulations wherein plumes of blue, yellow, or even white effluents were judged by inspectors making a mental translation of the Ringelmann chart. The United States Supreme Court has since refused to review, in effect thus supporting the finding.

In the other instance, the El Segundo station of the Southern California Edison Company was refused an operating permit on the grounds of the high sulfur content of the fuel proposed for use and of the inability to reduce the opacity of its plumes. Construction permits for additional proposed steam stations were also refused. As a result, the company has under-

Public Law 159—84th Congress

“ . . . it is hereby declared to be the policy of Congress to preserve and protect the primary responsibilities and rights of the States and local governments in controlling air pollution, to support and aid technical research to devise and develop methods of abating such pollution, and to provide Federal technical services and financial aid to State and local government air pollution control agencies and other public or private agencies and institutions in the formulation and execution of their air pollution abatement research programs. To this end, the Secretary of Health, Education, and Welfare and the Surgeon General of the Public Health Service (under the supervision and direction of the Secretary of Health, Education, and Welfare) shall have the authority relating to air pollution control vested in them respectively by this Act.

“The Surgeon General is authorized, after careful investigation, and in cooperation with other Federal agencies, with State and local government air pollution control agencies, with other public and private agencies and institutions, and with the industries involved, to prepare or recommend research programs for devising and developing methods for eliminating or reducing air pollution. For the purpose of this subsection the Surgeon General is authorized to make joint investigations with any such agencies or institutions.

“The Surgeon General may (1) encourage cooperative activities by State and local governments for the prevention and abatement of air pollution; (2) collect and disseminate information relating to air pollution and the prevention and abatement thereof; (3) conduct in the Public Health Service, and support and aid the conduct by State and local government air pollution control agencies, and other public and private agencies and institutions of technical research to devise and develop methods of preventing and abating air pollution; and (4) make available to State and local government air pollution control agencies, other public and private agencies and institutions, and industries, the results of surveys, studies, investigations, research, and experiments relating to air pollution and the prevention and abatement thereof.

“The Surgeon General may, upon request of any State or local government air pollution control agency, conduct investigations and research and make surveys concerning any specific problem of air pollution confronting such State or local government air pollution control agency with a view to recommending a solution of such problem.

“The Surgeon General shall prepare and publish from time to time reports of such surveys, studies, investigations, research, and experiments made under the authority of this Act as he may consider desirable, together with appropriate recommendations with regard to the control of air pollution.

“There is hereby authorized to be appropriated to the Department of Health, Education, and Welfare for each of the five fiscal years during the period beginning July 1, 1955, and ending June 30, 1960, not to exceed \$5,000,000 to enable it to carry out its functions under this Act and, in furtherance of the policy declared in the first section of this Act, to (1) make grants-in-aid to State and local government air pollution control agencies, and other public and private agencies and institutions, and to individuals, for research, training, and demonstration projects, and (2) enter into contracts with public and private agencies and institutions and individuals for research, training, and demonstration projects. . . .

“When used in this Act—

“The term ‘State air pollution control agency’ means the State health authority, except that in the case of any State in which there is a single State agency other than the State health authority charged with responsibility for enforcing State laws relating to the abatement of air pollution, it means such other State agency;

“The term ‘local government air pollution control agency’ means a city, county, or other local government health authority, except that in the case of any city, county, or other local government in which there is a single agency other than the health authority charged with responsibility for enforcing ordinances or laws relating to the abatement of air pollution, it means such other agency; and

“The term ‘State’ means a State or the District of Columbia.”

taken a \$1.75 million research program to find, hopefully, the answers to its difficulties.

Federal and State Legislation

Several attempts at Federal legislation on air pollution followed the 1948 catastrophe in Donora, Pa. Last year, for the first time, there was major national legislation on this problem. Pertinent sections of Public Law 159 (84th Cong.), which became effective on July 14, 1955, are reproduced in the inset.

In general, Federal legislation aims toward research, cooperation with local agencies, and financial assistance to other groups rather than in the direction of enforcement. In some of these fields the Federal Government is already active. Early in 1955, the Public Health Service intensified its program of air pollution research and technical assistance to State and local agencies at the Robert A. Taft Sanitary Engineering Center, Cincinnati.

It is difficult to keep track of all statutes pending in State legislatures. However, at least 70 bills were considered by 12 State legislatures in 1955, but the number may well be 100. Almost 40 of the 70 bills were before the California Assembly. They provided, among other things, for the amplification of the present law for the formation of county air pollution control districts, for the creation of regional control districts, or for statewide control. One bill, passed to remedy the problem in the San Francisco Bay area, permits the creation of the 9-county district mentioned previously.

New Jersey passed a State air pollution control statute in 1954. Enforcement under this act has been in the hands of the bureau of adult and occupational health of the State department of health. Codes covering various air pollution problems are being formulated by the Air Pollution Control Commission, a body representing industry, the general public, the technical societies, and other responsible groups in New Jersey. The commission recently completed work on its first code—on the control of open fires and dumps, which are major sources of air pollution in the northeastern section of the State. The code went into effect May 1, 1956, and affects scrap dealers and others with unsatisfactory incinerators.

Other States which considered air pollution legislation in 1955 were Arizona, Michigan, and Virginia. The Michigan bill would create air pollution control districts. Virginia's and Arizona's bills were for statewide authority. One bill in the Arizona House of Representatives went to the extreme of proposing to prohibit "the construction of oil refineries or other smoke-producing industries within 15 or 20 miles of any city or town."

Municipal and County Control

The tendency, in recent years, to convert from coal to oil or gas as a domestic fuel is helping to reduce smoke in urban atmosphere, but it does not completely eliminate it. A poorly adjusted oil burner can lay down a smoke screen worthy of a naval operation. Furthermore, high-sulfur oils contribute large quantities of sulfur dioxide to the atmosphere.

So many cities and towns have recently adopted or are presently considering smoke abatement or air pollution control ordinances that it is almost impossible to keep track of them. To mention a few:

Reno, Nev., Huntington and Wheeling, W. Va., Albuquerque, N. Mex., East Providence, R. I., Denver, Colo., Boyertown, Pa., Norfolk, Va., and Fair Lawn Borough, N. J., have all adopted new ordinances. Cleveland, Ohio, is modifying its present ordinance, and Charlotte, N. C., is reviving its old ordinance.

These are only isolated examples. However, the pattern of municipal legislation is much the same. In the absence of expert technical guidance, most local governmental bodies perforce use the scissors-and-paste method. They base their new ordinances on those of nearby or well-known cities or occasionally utilize so-called "model ordinances."

The typical city smoke control ordinance is relatively simple. It provides for the prohibition of black smoke of a given density (usually No. 2 Ringelmann) and forbids the emission of fly ash of a certain concentration (usually not exceeding 0.85 lb. per 1,000 lbs. of gases).

There is a trend, however, toward broader municipal air pollution control ordinances, based on the Los Angeles County ordinance as a model which prohibits the emission of all toxic

and nuisance effluents, with even specific levels for certain gases such as sulfur dioxide.

One of the most noticeable results of the Los Angeles smog activity has been a tendency for other areas to copy its regulations. Honolulu, Hawaii, is one; Louisville, Ky., was another, but then abandoned the idea and is presently embarked upon a comprehensive air pollution survey.

Elsewhere across the country there are current efforts to emulate the California model county control districts.

The county control-district type of air pollution agency will be more prevalent in the future. It solves the problem of control in the large city that is unable to control smaller, neighboring suburbs. For similar reasons interstate compacts probably will be employed to handle the problems faced by New York with pollution drifting from industrial New Jersey, by St. Louis with pollution drifting from the adjacent industrial areas across the river in Illinois, by Cincinnati with pollution from Kentucky communities, and by many other cities.

Cost of Control

The control of air pollution is not going to be cheap. In fact, it is going to be expensive. The cost of providing pure water or good sew-

age disposal was high in dollar outlay although not in relation to the advantage gained. It will be the same with pure air. But, as with water and sewerage costs, the outlay may be less than the cost of continuing pollution. This consideration provides the opportunity for a carefully planned program of education.

In many communities, educational programs are being assumed by the chambers of commerce. Programs may be undertaken by a college or university or in some areas by research organizations, such as Stanford Research Institute of California with its series of air pollution symposiums, Mellon Institute of Pittsburgh with its Industrial Hygiene Foundation meetings, the Air Pollution Foundation, the Southern Research Institute, and others.

Research organizations can aid also in the development of community educational programs by bringing to air pollution control a scientific and impartial point of view. Surveys and other studies will help in determining whether a pollution problem is real and whether the health considerations are transitory and superficial or chronic and basic. Research projects can be set up to study the nature of air pollution and how it can be best eliminated or controlled. These great economic, technological, and social issues challenge the statesman and legislator no less than the industrialist, scientist, and engineer.

Mintener Resigns

Mr. Mintener

"It is a matter of deepest regret to me and, I know, to all my associates in the Department, that Bradshaw Mintener is resigning his position as Assistant Secretary of Health, Education, and Welfare.

"In the two years Mr. Mintener has held this post, he has made a great contribution to the work of this Department. The fine spirit of our organization, particularly in the field, is due in large measure to his activities. His sound advice on the problems of the Food and Drug Administration has been instrumental in laying a proper foundation for a greatly needed expansion of its activities which are so vital to everyone in the Nation.

"I am sorry Mr. Mintener could not stay longer in Government service."

—MARION B. FOLSOM,
Secretary of Health, Education, and Welfare.

Group therapy at the National Training School for Boys brings out into the open the warfare delinquents wage against adult society and the fears and hungers underlying it.

Group Therapy Behind Locked Doors

By SEYMOUR RUBENFELD, Ph.D., ROBERT SHELLLOW, Ph.D., and JACK L. WARD, M.D.

TO GIVE the reader some idea of the functions of the psychiatric unit in a juvenile institution, as well as some feeling for the types of problems faced in working with these youngsters, we shall attempt to describe the unit in the National Training School for Boys. The training school is for delinquent boys under the age of 18 who have been committed to the custody of the United States Attorney General. The school is operated in the District of Columbia under the auspices of the Federal Bureau of Prisons. We three, a psychiatrist and two clinical psychologists, form the psychiatric unit.

The authors are the three members of the psychiatric unit which they describe. Drs. Rubinfeld and Shelllow, the two psychologists on the staff of the National Training School for Boys, Washington, D. C., received their graduate degrees from Pennsylvania State University and the University of Michigan, respectively. Dr. Rubinfeld interned at Warren State Hospital and Hollidaysburg State Hospital in Pennsylvania. Most of Dr. Shelllow's earlier experience was with Veterans Administration hospitals at Ann Arbor, Dearborn, and Fort Custer, Mich. The third member, Dr. Ward, spent his internship and residency years at Delaware Hospital, Wilmington, and St. Elizabeths Hospital, Washington, D. C., before he was appointed acting chief of the NTS Psychiatric Service on April 1, 1955.

First of all, it is important to know what kinds of boys get into trouble and are sentenced to an institution of this type. Roughly, the boys with whom we deal fall into four categories.

Probably the most prevalent type is the boy we might call the predatory delinquent. His socioeconomic background is, more often than not, one of deprivation. His own family is usually large and disorganized. He may have experienced several foster home placements. The parental figures he has known may have bombarded him with the deepest kinds of rejection, ranging from exploitive overprotectiveness through cold indifference and neglect to sadistic hostility. He emerges from this trial of childhood with his ability to accept his dependence on others severely crippled. Estranged from adults, he sees them as persecutors. He throws himself against both adults and the social values and mores to which they conform. Adrift in the streets, he imbeds himself in the society of other adolescent outcasts. Here, he finds firm and uncompromising articles of conduct, the rules of the delinquent gang that sanction and codify ways of vengeance and means of exploitation.

Falling into a second group are boys who get into trouble for neurotic reasons. Many come from the middle class and often from upper middle-class socioeconomic backgrounds. Their families are frequently intact and may even be relatively well knit. These boys have

in these boys 24 hours a day. Supplement their understanding and offer suggestions for the handling of specific behavior problems. Occasionally incidents occur which demand consideration. For example, a boy may have a frank psychotic break, and it is necessary to transfer him to a psychiatric hospital. Recently, we have been placing a small number of disturbed boys on mood-ameliorating drugs such as Thorazine and Meprobamate. These boys usually show obvious anxiety or some degree of depression as an aspect of their general poor adjustment in the institution.

Our major treatment effort is invested in group psychotherapy. Many acting-out adolescents are not amenable to individual psychotherapy. These boys immediately react in an uncritical and uncontrolled fashion to inner prompts. This basic one-to-one relationship is too threatening for them. Firmly embedded in their personality is overwhelming distrust of the adult and fear of losing their fragile identity. They seem to function better in a group. Many of them find support, strength, and comfort in a gang formation. The adolescent urge to conform can, in the group setting, be utilized by the therapist in working toward the therapeutic goal of self-examination and self-evaluation.

By using the group treatment process, we now see 45 boys in 5 groups, each consisting of 5 to 10 members. We try to keep about 8 boys in each group, finding that this number allows for the development of opposing factions within the group itself. Smaller groups do not appear to be so successful because they tend to be more clannish. For example, 4 boys may form their little clique in a group of 5 and completely drown out the lone dissenting voice. Larger groups are unwieldy and difficult to control.

Getting a New Group Under Way

In selecting candidates for group therapy, we again employ the technique of the group interview. We call together anywhere from 8 to 10 boys, evoke response, encourage interchange of ideas, and observe the role that each adopts toward us and toward the other boys. In the course of the discussion, we explain our pur-

pose, outline the aims and the nature of group therapy, and leave to the individual boy the choice of joining.

We avoid taking into therapy boys who make absolutely no effort to contact adults. We have found that they are not interested in group therapy, and, if they do enter a group, they get little out of it and soon leave it. We also avoid bringing in boys who have a compulsive need to act out their slightest whim or fear. We have had trying experiences in which these extremists continually disrupt groups and bring therapy to a stop.

But we have no objection to acting-out if it is checkable. It is one of our basic stocks in trade. Almost all our boys display this characteristic to some degree, and we work with it. All we require is that a boy, in addition, have some capacity to think and to speak in the face of his own anxiety or frustration and that he be ready to admit that he has questions about himself.

Boys come to the groups voluntarily. If they are interested in joining after the group interview, we take them in on the condition that they will remain at least 1 month or for 8 sessions. If at any time they decide to leave, if they feel that they are not getting anything out of it, we usually ask them to continue for 2 or 3 sessions after they have requested termination.

What are the boys who come into group therapy like? First and foremost, they have an arsenal of suspicions concerning adults and in particular the therapist, who becomes the momentary focus for those concealed and sometimes overtly expressed attitudes. Each boy has his fallen god or goddess. The boys remember the disappointing experiences they have had with adults. They remember the inconsistency of treatment and the inability of adults to control them. The result is that they bring to any relationship with an adult a tremendous amount of hostility—a hatred and a vengefulness which are clouded and confused by strong needs for direction, guidance, and love.

One way in which this hostility is expressed can be seen in a boy's comments in his first group therapy session: "Why did you choose me? Why not leave me alone—I'm not crazy."

Later, this suspiciousness may show up as:

John snaps to them, "Aw, don't listen to him (the therapist). He doesn't really give a — either."

The whole group is stunned by this statement. George and Sam snicker uneasily. The therapist tries to get John to amplify his feeling, but before he can get more direct expression of hostility, the group slides deftly away and begins talking about custodial officers in general. The session ends with general griping about the institution.

The next session starts with John mischievously asking the therapist for a cigarette. When the therapist questions John about his relentless nagging for the cigarette, John blows up. "All the time you're asking why, why . . . we never get anything out of you." John suddenly sees himself as the anti-"Doc" hero, and it is obvious that he is enjoying the situation. He and George and Sam begin to giggle. John calls the Doc a "squealer" and accuses him of spying and making reports on everybody in group therapy. "You're yellow, Doc. You don't have any guts at all. You wouldn't last twenty minutes in prison."

Meanwhile, the therapist has observed Ritchie and Pete, among others in the group, no longer looking scared. On the contrary, Ritchie seems to show signs of "righteous indignation" at John's last statement. Ritchie says under his breath, "Aw, —."

The therapist notes Ritchie's reaction and says, "Group, what do you think of what we are hearing?"

Ritchie says derisively, "Don't listen to him, Doc, he's way off."

John turns on Ritchie with vengeance. "Who asked you, Punk? You're always eating somebody. What do you know about anything? You're just a clock (newcomer). You haven't met your six-piece yet (6 months' reclassification at which a boy can request a change in program)."

By this time, the lines of the battle are clearly drawn. Pete sides with Ritchie, and George with John. Others lean forward attentively. Ritchie counterattacks against John. "You're just taking it out on the Doc because you were stupid enough to get thrown in the jug. You always do this. Whenever you foul yourself up, you always blame it on somebody else."

At this point Ritchie and Pete begin to cite instances of John's asking for trouble, getting into it, and blaming others.

John retaliates by describing situations in which Ritchie has gotten away with things by "eating" (apple polishing) the officer and implies that Ritchie is trying to do that now with the therapist. The therapist says, as quietly as possible, "I guess someone wants to kick me, and someone else wants to suck me in, but it's pretty hard to tell who wants to do what."

The group goes suddenly quiet, and there is embarrassed laughter on both sides. John nervously tries to maintain his lead and at the same time turn the therapist aside. "Aw, Doc, we were only kidding, we were just trying to get your goat."

The therapist asks, "I wonder why?"

At last, John hits on a way to retreat without loss of face. "Here we go again: What, Why, When, Where. If the Doc was running 'You Asked for It' on TV, he would read the letters and then look out at the audience and say, 'Why should I?'" This amuses the group. Tension is broken, and the group as a whole runs from the dangerous challenge given by the therapist into humorous accounts of instances in which the question "Why?" would be ridiculous. The session ends with the therapist remarking, "I guess you'll be comfortable enough eventually to talk about yourselves."

Clues to Delinquent Behavior

The conflict between members and therapist, and among members, comes up again and again in different contexts. Sometimes the therapist is successful in focusing on the feelings and disappointments the boys have experienced with their parents and other significant people in their past life. When this happens, he attempts to relate their feelings to the feelings they are experiencing toward authority in general and toward the therapist in particular.

Movement in and out of such crises is characteristic of our groups. The group is like a self-sealing innertube: Occasionally a boy or the therapist succeeds momentarily in puncturing the resistance of the group, and powerful feelings explode before the wall of denial fuses again. Through repetition of this kind of

"Why do you do this, Doc? What's in it for you? You must be a spy—it all gets back to the superintendent." Or: "You're just experimenting with us . . . nobody really gives a ——— about us. You bucking for Captain?"

It has been our experience that these attitudes are present in all boys but become expressed in various forms by different members of the group.

Use of Group Dynamics

From the preceding description it may appear that there is an incessant war of boys against therapist. As a matter of fact, when one faction of the group becomes intoxicated with the power of their anti-"Doc" attitudes, others in the group will begin to defend authority and attempt to stem the tide of violence. At this point a polarity is set up within the group: Struggle for power or a civil war develops along the lines of a personal duel or of gang warfare.

The polarity emerges because of the deep hungers for an infantile protective relationship with the therapist and because of the resentments stirred in the more aggressive boys when the therapist does not offer this relationship. The group splits into factions because some boys can't afford to see the therapist attacked. The boy who is driven to defend the therapist when he sees the attack launched is afraid that the therapist will attack him. Despite this apparent alliance with the "Doc," the boy's reaction is still based on the fact that he has identical, though not quite so obvious, feelings against the therapist's authority.

The therapist, with his relative understanding of the situation, is generally not incapacitated by anger with those attacking him or taken in by those defending him. Attempting to recognize both of the antithetical reactions for what they really are, he bases his comments and interventions on the insight derived from his own natural responses. He stands his ground and attempts to lead from strength. As therapist, all his interventions are directed toward clarifying to the entire group the issue of their basic struggles with dependence.

The group dynamics described in the preceding paragraphs are probably best seen in the

actual transactions and interactions of a group therapy session.

A Group Therapy Session

John has stolen 17 cars, was in 2 previous institutions, and makes his way by gambling, "conning," and setting up "strong arm" cliques to get what he wants. At the moment he has the center of the stage. He tells about a movie the boys saw on television in which a man paroled from prison can't make a go of it in society. Nobody will give the ex-convict a job; his friends avoid him; and jobless, friendless, discriminated against, he gets drunk one night and gets returned to the prison as a parole violator.

As John gets more and more worked up about the injustice of it all, George and Sam go from quietly ignoring the group in their card game to sparring and light body punching. Peter and Ritchie are quietly listening and watching the therapist's reaction.

The therapist notes John's involvement and says, "Well, John, you seem to feel that was a pretty dirty deal."

For the first time, John centers a challenging gaze on the therapist. "You're ——— right this was a dirty deal. Nobody ever gives a guy who has done time a chance."

"How come?" the therapist asks.

"They're all down on a guy like that, they hate his guts. They don't let you alone when you're on parole. You're just sitting on your porch, and the cops keep coming around your house every night, and they're always frisking you . . . they're always needling you."

George turns aside from his sparring and throws out, "And they're all like that, whether they're inside the prison or outside."

The therapist says in an offhand way, "You seem to feel that people are down on you."

At this point, John bursts out, "You said it, Daddy-o," and goes on to tell how a cottage officer "threw" him into a segregation unit for what John considered to be an unjust reason. George and Sam join in. They break off their sparring and recount similar "mistreatment."

The therapist turns to the boxers. "George . . . Sam, you seem to be getting hot under the collar about this too."

Causes of Death Among College Students

—A Study of 209 Deaths at Yale University, 1920–55—

By HENRY M. PARRISH, M.D., M.P.H.

WHAT DISEASES and conditions kill our college students? How does mortality among them compare with that of the general population of the same ages? Are there specific diseases to which college students are more prone to succumb?

In answer to these questions, I submit the results of a study of deaths among the students at Yale University during the period 1920 through 1955. The causes of death among these students are set forth, and they are compared with the causes reported for other college groups and for the total population of the United States. It is hoped that these data will focus attention on some of the important student health problems and that they will emphasize the necessity for action on the part of colleges and universities in fulfilling their responsibility for student health needs.

Study Materials and Methods

The files of the department of university health, the department of mental hygiene and psychiatry, and the alumni records office of Yale

University were the primary sources of information. A student death was defined to include students who died during the academic year or summer vacation and those on medical or psychiatric leave of absence who died within 1 year after withdrawal. Calendar years, instead of academic years, were used to record the year of death.

To confirm the death and to determine the cause, the individual medical records at the department of university health were examined first. For students who died as a result of suicide and who had been seen in the department of mental hygiene and psychiatry, the records of that department were studied.

The hospital and autopsy reports of 23 students who died from medical and surgical diseases, or their complications, at the New Haven Hospital were also examined. Several errors in the original data were found and corrected on the basis of these records. Autopsy findings were used to correct clinical diagnoses whenever such findings were available.

Much valuable information was obtained from the individual records of the deceased in the alumni records office. For most of the students who died, these records contained the date of death or of withdrawal for medical or psychiatric leave of absence and a statement of the cause of death from the registrar of vital statistics in the town where death occurred. For most of those who died from accidents or suicides, they also contained newspaper clippings concerning the incident.

The name of any student who could not be

Dr. Parrish is assistant physician, department of university health, Yale University. He was a fellow in public health at the university's School of Medicine from September 1955 to June 1956, when he received the degree of master of public health. This paper reports a study he made in partial fulfillment of the requirements for that degree.

crisis, there is a gradual sharpening of a boy's image of himself and a lessening of his hate. As he grows more comfortable with himself, he finds it less frightening to stand alone, and the need to blame and hate others for his own inadequacies abates. He is able to stand apart equally from attacks on, and defenses of, the therapist by the less advanced members of the group, and he can criticize both sides. He begins to talk openly about the personal consequences of his own experiences, and he begins to lay realistic plans for his future.

Group therapy not only provides a workable vehicle for effecting change in these adolescents

but also supplies many clues to the nature of the developmental processes producing delinquency. The reader may have observed that most of the diagnostic and therapeutic tools which we employ are not at all new. The interviews, diagnostic tests, and the therapeutic relationships are much the same as those used in the conventional psychiatric setting. We are entirely content with these techniques because, as yet, our knowledge of the delinquent is far from complete. The evaluation of our skills must wait upon the direction of resources toward a systematic observation of the rebellious adolescent.

PHS Films

Flocculation Test for Trichinosis

35 mm. filmstrip, color, sound, 11 minutes, 85 frames, 1956.

Audience: Laboratory directors and experienced laboratory technicians.

Availability: Loan—Communicable Disease Center, Public Health Service, 50 7th Street NE, Atlanta 5, Ga. Purchase—United World Films, Inc., 1445 Park Avenue, New York 29, N. Y.

The use of the modified bentonite flocculation test is the subject of this highly technical procedural film-

used and the complete procedures for the test, including reconstitution of the bentonite, preparation of the antigen, standardization of the reagents, and typical appearance of the flocculated particles.

Poultry Hygiene Series: Plant Layout and Construction Operating Procedures

35 mm. filmstrips, color, sound, 10 minutes each, 73 and 83 frames, respectively, 1956.

Audience: State sanitarians, public health administrators, and plant operators.

Availability: Loan—Communicable Disease Center, Public Health Service, 50 7th Street NE, Atlanta 5, Ga. Purchase—United World Films, Inc., 1445 Park Avenue, New York 29, N. Y.

These two films show the application of the 1955 United States Public Health Service Ordinance

and Code to (1) the construction and layout of a medium-sized plant and (2) operating procedures.

The first film is illustrated by a blueprint of a plant showing five main divisions: (a) receiving and holding room, (b) dressing room, (c) eviscerating room, (d) packaging room, and (e) refrigerating room. Typical operations and construction details pertinent to sanitation in each division are shown.

The second film illustrates the operational procedures in a typical

plant by a series of photographs of (a) poultry arriving from the farm, (b) ante-mortem inspection, and (c) step-by-step details of the cycle of processing poultry. Sanitary aspects are stressed in each operation: killing, defeathering, eviscerating, packaging, and storing or delivering to the consumer. The necessity for personal hygiene among the workers is emphasized.

strip. It is a simple, rapid, and specific test for the laboratory diagnosis of trichinosis.

The film depicts the materials

¹ Rates for white males aged 15-24 years, published by the National Office of Vital Statistics in: Vital Statistics of the United States, 1950, vol. 1, p. 194; Annual Summary for 1954, part 2, Monthly Vital Statistics Report, vol. 3, No. 13, May 13, 1955; Annual Summary for 1955, part 2, Monthly Vital Statistics Report, vol. 4, No. 13, May 28, 1956.

² Estimated.

ues is statistically significant according to the chi-square test.

The vital statistics of the United States during the past half century reflect some striking changes in causes of death. Of the 10 leading

causes in 1900, 5 were communicable diseases. Pneumonia and influenza ranked first; tuberculosis, second; diarrhea and enteritis, third; diphtheria, ninth; and meningitis, tenth. In 1955, only one of these, pneumonia and influenza, was among the first 10 and none was among the first 5 (3).

To determine the trend in causes of death among Yale students, the numbers of deaths from accidents, infectious diseases (including pneumonia, meningitis, septicemia, tuberculosis, encephalitis, poliomyelitis, and others), and suicides were plotted for 10-year periods, as shown in the chart. Deaths due to infectious diseases have declined steadily. Accidents have remained at a high level and have been the most prominent cause of death in students since the decade 1930-39. The number of suicides rose sharply during the decade 1930-39, the depression years, then declined during the next decade, the war and postwar years.

Discussion

The finding that mortality among the students at Yale University is generally much

traced by one of the above methods was submitted to the registrar of vital statistics in the town where death occurred. The deaths of 21 students were confirmed in this manner.

Information concerning the cause of death was obtained from one or more of the above sources for 207 of 209 student deaths. For one student who died abroad, death was reported as accidental without specific details, and the cause of death for another student could not be determined.

The data collected on each student death included the name and class of the student, the date of death, the age at the time of death, the cause of death, and the place where death occurred. Additional information on accidental deaths and suicides was obtained from newspaper clippings describing the circumstances of the death.

Statistical Results

There were 209 deaths among the students at Yale University from 1920 through 1955, an average of slightly less than 6 each year. The only year in which no deaths occurred was 1920. The largest number of students died in 1949, when 16 deaths were recorded.

Of the 209 students, 86 percent were 15-24 years of age, 13 percent were 25-30 years, and 1 percent were over 30 years. Ninety-five percent were white males, and 5 percent were white females.

The five leading causes of death among the Yale students were accidents (43.8 percent), suicide (12.0 percent), heart and circulatory diseases (7.7 percent), pneumonia (7.2 percent), and infections of the central nervous system (6.3 percent). Of the accidental deaths, more than half were caused by motor vehicle accidents. The only other data available on deaths among college students are those reported by Diehl and Shepard from a study of deaths in 327 students at 9 universities during the period 1925-35 (1). In that study, the five leading causes were accidents (26.3 percent), heart and circulatory diseases (10.1 percent), suicide (8.0 percent), pneumonia (7.3 percent), and tuberculosis (6.4 percent). Again, motor vehicle accidents were the cause of more than half of the accidental deaths. The data on cause of death

obtained in these two studies are given in table 1.

Since 95 percent of the Yale students who died were white males and 86 percent of them were in the 15-24 age group, the deaths at Yale are compared with the deaths among white males aged 15-24 years in the total population of the United States. From the national death rates for this group, the number of deaths expected among Yale students each year of the study period was calculated. The results, presented in table 2, reveal that the number of deaths at Yale was lower than the number expected for every year except 1949. That year an airplane disaster in Seattle, Wash., took the lives of 11 students.

To compare the causes of death among Yale students with the causes for the total population, 1950 rates for white males aged 15-24 years as reported by Collins and his associates were used (2). Since there was only one death at Yale in 1950, these rates were applied to student deaths during the period 1946 through 1955. As shown in table 3, for only two causes was the number of deaths among Yale students above expectation. They were suicides, with 5.1 deaths expected and 7.0 deaths observed, and cerebral hemorrhage, with 1.2 deaths expected and 2.0 deaths observed. Neither of these val-

information around which a preventive educational campaign can be constructed.

American colleges and universities have an obligation, a duty, to protect and promote the health of their students. Are our institutions of higher learning fulfilling this obligation? It is estimated from a 1953 survey of 1,157 colleges that of every 3, 1 has no clinical service, 1 has clinical services for minor disorders, and 1 has clinical facilities for both major and minor disorders (6). Thus, it appears that there is a definite need to stimulate the interest of administrators, teachers, trustees, and parents in health and medical facilities for college students.

Summary

1. In a study of the 209 student deaths at Yale University from 1920 through 1955 the following were found to be the most common causes of death: accidents (43.8 percent); suicide (12.0 percent); heart and circulatory diseases (7.7 percent); pneumonia (7.2 percent), and central nervous system infections (6.3 percent).

2. Deaths from infectious diseases have decreased, but accidental deaths have remained high. Accidents have been the number one

killer of college students since the decade 1930-39.

3. The number of deaths among the Yale students was lower than would be expected if national death rates had prevailed. There were more suicides among the students than would be expected, but the difference was not statistically significant.

Porterfield Named Assistant to the Surgeon General

Dr. John D. Porterfield, a career officer of the Public Health Service since 1939, assumed his duties as assistant to the Surgeon General on October 16, 1956.

He comes to his new position from Ohio where he was director of the Ohio State Department of Health from 1947 to 1954 and director of the Ohio Department of Mental Hygiene and Correction since 1954.

In his new assignment, Dr. Porterfield will give particular attention to the fields of chronic disease and aging.

He is chairman of the editorial board of the American Journal of Public Health; chair-

man of the mental health section of the American Public Health Association; former secretary and later chairman of the association's health officers section; former secretary and later vice president of the Association of State and Territorial Health Officers, and a member of the Scientific Study and Planning Committee of the Joint Commission on Mental Illness and Health. He also is associate professor of preventive medicine at the Ohio State University Medical School at Columbus and a visiting lecturer at the University of Michigan School of Public Health at Ann Arbor.

Number of deaths from accidents, infectious diseases, and suicide among Yale University students for 10-year periods, 1920-59

lower than that of the general population of the same ages is not unexpected, for several reasons: College students, for the most part, are adolescents and young adults in good health. The majority of the students at Yale are from an average or an above average socioeconomic group. Most of them eat in the college dining halls, where well-balanced meals are served. Yale students are a selected intellectual group, who are probably better informed about health matters than the general population of the same ages. College entrance physical examinations help detect disease and single out for special care students with medical problems. Complete medical care is available to all students 24 hours a day, 7 days a week, while school is in session.

This study clearly points to accidents as the number one health problem among college students, just as they are in the general population in the age group 15-24 (4). At Yale, accidents accounted for more deaths than the next five most common causes combined. Accidental deaths have continued at a high peak, while deaths due to infectious diseases have been on the decline. There are no reliable statistics regarding the incidence of accidents at Yale, but preliminary data suggest that 1 Yale student in 4 has an accident requiring medical treatment each year.

In the general population, motor vehicle accidents cause more deaths than any other type of accident among persons under 65 years of age (4). This proved true at Yale, where 23.6 percent of all deaths were caused by motor vehicle accidents. Most of the motor vehicle deaths occurred outside Connecticut, and most of the ones in Connecticut happened outside New Haven. Closely related to these findings is the fact that most of the fatal motor vehicle accidents took place over the weekend. Since Yale is primarily a men's college and since there are no girls' schools in the immediate vicinity, many of the undergraduate students travel long distances in automobiles over the weekend to see young ladies. Other students drive home to spend the weekend with their families.

Suicide was the second most common cause of death among Yale students. The number of suicides was highest during the depression years and lowest during and immediately following World War II, a pattern which is consistent with the pattern of suicidal deaths for the general population. There is no clear explanation for this phenomenon, but some authorities feel it is because the potentially suicidal individual diverts his thoughts, and his pent-up anger, from himself to the war effort and the potential enemy.

Most of the causes of death among college students are amenable to prevention and treatment programs. Communicable diseases are today readily controlled with antibiotics. Through health education, it should be possible to prevent many accidents. With the provision of adequate psychiatric counseling, it may be possible to reduce the number of suicides. Promotion of mental health is an important function of any college health department, since it has been estimated that about 10 percent of the students need professional help with their emotional problems (5).

The college situation affords unusual opportunities for a productive campaign against accidents. College students are in a learning situation; they are maturing individuals; and they are congregated together where they can be reached. As a result of this study of deaths at Yale, plans are now being made for an investigation of accident morbidity at the university. This investigation should provide

The survey site was the arts and crafts building located on the reservation at Cherokee Indian Village. Facilities for determining heights and weights, taking nutritional histories, and taking and processing blood samples were set up inside. Mobile X-ray units from the North Carolina State Board of Health were parked behind the building.

Indian Agency school buses carried many participants to and from the survey site. Entire families came and the scene rapidly assumed a festive air.

The weight and height of each participant was determined by volunteer workers. Results are being compared with a study of weights and heights of the Cherokees made some 30 years ago.

Nutritionists from the North Carolina State Board of Health recorded diet histories for all participants being screened for diabetes.

The participants queued up preparatory to entering 1 of 3 curtained-off areas where blood samples were drawn for diabetes screening, serologic tests for syphilis, and determination of serum vitamin levels.

Cherokee Indian Health Survey

By CHARLES M. CAMERON, Jr., M.D., M.P.H.

oU l h j

These characters in the Cherokee alphabet mean "Are you well?" They are used as a greeting.

TO ASSESS health conditions among the Cherokee Indians in North Carolina, a multiphasic survey was conducted at the reservation in April 1955. It was a joint venture of the Bureau of Indian Affairs, the Public Health Service, the North Carolina State Board of Health, the Jackson-Macon-Swain District Health Department of North Carolina, and the University of North Carolina School of Public Health.

Participation in the survey was limited to reservation inhabitants 15 years old or over. During a 2-day examination period, about 1,000

of the 2,500 to 3,500 residents received the various tests. The entire group received chest X-rays and serologic tests for syphilis, as well as height and weight determinations. Those 15 to 25 years were examined for blood vitamin levels. Those 25 years or over were asked for information about their diets and received diabetes screening tests.

In addition to a team of workers from the Federal, State, and local health agencies, more than 50 volunteer workers from the reservation and surrounding communities participated in the survey. Success of the operation is credited to the excellent presurvey educational and informational program conducted by personnel of the district health department and the Cherokee Indian Agency.

Results from the survey confirm that the Cherokees in North Carolina enjoy a state of health superior to that of many other Indian groups in the United States. The health of this group compares favorably with that of other residents of the mountainous area along the Tennessee-North Carolina boundary.

Dr. Cameron, associate professor of public health administration, University of North Carolina School of Public Health, was director of the team of Federal, State, local, and volunteer health workers who planned and conducted the screening project at the Cherokee Indian Reservation. His avocational interest in photography has made possible this picture story of the project.

Serologic Survey for Syphilis In Migratory Labor Camps Of Upstate New York

By EVAN W. THOMAS, M.D.,
and JOSEPH GIORDANO, M.S.

CASE FINDING of syphilis among migratory laborers has been a difficult problem. In New York State the same facilities for venereal disease control are available to migrants as to all residents of the State. However, many migrants do not know about these facilities. Even when they do, many are reluctant to use them unless incapacitated by pain or illness. Clinics, whether operated during the day or night, have not been a satisfactory means of discovering more than a portion of the syphilis believed to be present. Therefore, the policy adopted by the Public Health Service of providing funds for serologic surveys for syphilis to be conducted in the labor camps was welcomed in New York State.

New York is a large State, and migrant workers during the summer and fall months are scattered throughout, from Long Island to the most western counties. Since many of the camps accommodate less than 20 migrants, serologic surveys reaching all migrants in the State are obviously impractical. However, with proper planning, large numbers can be tested by conducting surveys in the larger camps. To accomplish this, the location and

census of labor camps must be known, and operations should be confined to areas where the least possible time is needed for travel from camp to camp. Sanitation officers of the three New York State districts in which the surveys were conducted were very helpful in providing this information and in planning contacts with the camp owners and managers prior to the actual surveys.

The efficiency of the campaign was greatly augmented by the full cooperation of the personnel in these offices. In the last analysis, however, the success of the survey depended on the personnel of the teams in the field. The young men and women composing these teams worked many more hours than the usual 40 in a week. They refused to be stopped by difficulties that could be overcome by additional planning and hard work. They worked well with each other and wasted little time. Had it been otherwise, the number of patients examined would have been much smaller.

The Operating Teams

Starting July 11, 1954, and finishing September 23, 1955, two teams, consisting of a clerk and a nurse, or technician, set out in doing venipunctures, operated in camps located in eight counties of northwestern New York State. Blood was withdrawn from the migrants after they returned from the fields in the morning or while they were in camp on rainy days. With rare exceptions, the cooperation of migrants, 15 years of age or over, was easily obtained and operations within the camps usually continued until 10:30 or 11 p. m. Owing to advanced notice, the workers were prepared for the visit at night, and little time was lost in getting under way after the team arrived. Frequently, each team visited several camps in a single night. During each working day, one of the members of the two operating teams visited the camps to be surveyed that night, thus assuring a good reception and a well-organized plan of operations for the night.

As the nearest serologic laboratory equipped to handle the increased volume of blood speci-

Dr. Thomas is a consultant in venereal disease control, New York State Department of Health. From 1936 to 1955 he was director of the syphilis service in Bellevue Hospital, New York City. Among his publications on venereal disease is the book, "Syphilis: Its Course and Management," 1949. Mr. Giordano is a health program representative in the venereal disease control field, assigned by the Public Health Service to the New York State Department of Health.

A Public Health Service officer assigned to the North Carolina State Board of Health took blood samples. Of 973 serologic tests for syphilis, only 5 were positive. Four of these cases were found to have had adequate treatment.

The Hewson Clinotron, loaned by the Public Health Service, was used in screening blood samples for elevated blood sugar. Of 761 persons over 25 years of age, 24 diabetes suspects were singled out. Followup on these is in progress.

Final step was a chest X-ray. More than 90 percent of the 1,020 persons examined were essentially negative. Of 31 persons selected for rescreening, 16 were found to have tuberculous infection, but all were in an inactive stage.

Blood specimens were frozen and then shipped to the University of North Carolina, where serum vitamin A and C determinations were done. Preliminary reports indicate that the group surveyed tends to have a lower plasma ascorbic acid level than certain well-nourished population groups in the north-eastern States. The serum vitamin A levels compare favorably with results obtained in other regional surveys.

Although not participants in the survey, Cherokee youngsters exhibited great interest in the activities. The two pictured are watching their parents as they progress through the survey line. →

tating reaction coming to our attention was in a woman who was hospitalized for "serum sickness."

Test Results

Serologic test results were received for 5,176 persons of which all but 155 were nonwhite (table 1). The white persons tested, although temporarily living in labor camps, were not migrants from outside New York State. Among these 155, there was 1 reactor in 127 men and 1 doubtfully positive result in the 28 women, making an overall reactive rate of 1.29 percent. Both were in the age bracket 15-24. The man had received no previous treatment, and the woman was given additional therapy.

The overall reactive rate for the 5,021 non-

white persons was 22.59 percent. The rate of positive and doubtful reactivity for nonwhite women ranged from 4.92 percent in the small number of 61 girls under 15 years old to 41.12 percent in women aged 45-54 and was consistently higher than for men of all ages up to this point (table 2). For persons over 55, the rate for women was 28.6 percent compared with 41.9 percent for men. For all nonwhites, the range was from 3.39 percent in children under 15 years old to 43.41 percent for persons aged 55-64.

A slightly higher (although generally consistent) percentage of doubtful reports occurred among women than men. Experiences with the specific treponemal immobilizing antibody tests show that more biological false-positive serologic tests for syphilis are found in women

mens was usually 20 to 60 miles from the headquarters where the teams were working, one of the team members motored to the laboratory each morning to deposit the specimens drawn the night before and to pick up reports on those that had been tested. In this way, workers found to have positive reports could be interviewed and treated, if necessary, within several days at the most after the blood had been withdrawn. Treatment was given by a physician or under the direct supervision of a physician. Although treatment was arranged at the shortest possible interval after blood was taken, it was impossible to find all migrants whose serologic tests were reported positive or doubtful. In some cases, blood specimens were taken from workers who were only visiting the camp on the night blood was withdrawn. In other cases, workers had transferred to another camp or were absent the night treatment was given. Repeated visits to a camp to find one or more seropositive cases were usually impractical. About 10 percent of the nonwhite persons with positive or doubtfully positive test reports could not be interviewed or examined for treatment.

Treatment

In mass surveys of this kind, the advantages of examining and treating the largest possible number of persons must be weighed against the desire to maintain high standards of diagnosis. In the absence of clinics and the full cooperation of patients, thorough diagnostic examinations are impossible. In the migrant survey,

quality of diagnosis was frankly sacrificed for quantity. As a result, probable diagnoses were based largely on the report of a single serologic test for syphilis performed by a flocculation technique usually used only for screening purposes. Attempts were made to obtain histories from all patients with positive or doubtful test reports. The histories were frequently vague and unreliable. Therefore, we treated, on suspicion, most patients with doubtful tests for syphilis and no reliable history of previous adequate treatment.

Treated patients were given a card with the date and the kind and amount of therapy received. They were told to keep the card with their Social Security card or driver's license and to show it at future medical examinations. Even though some or many of these cards may be lost, unnecessary re-treatment might be avoided in numerous cases, if the practice of providing migrants with such a record of treatment were to become universal.

Treatment consisted of a single injection of 2,400,000 units of benzathine penicillin G, contained in a disposable syringe. This dose, concentrated in a total volume of 4 milliliters, caused varying amounts of pain and soreness at the site of injection. A few patients coming to our attention were incapacitated by pain for periods of at least several days. The single injection is convenient and it saves time, but complaints of severe pain would undoubtedly have been diminished or avoided had 1,200,000 units of a less concentrated suspension been injected into each buttock. The only other incapaci-

The Use of the Membrane Filter Technique for Testing Water Supplies in the Field

By MALCOLM C. HOPE, Ch.E., M.P.H., and ARTHUR H. NEILL, C.E., M.P.H.

TWO STUDIES conducted in western national parks during the early summer of 1955 evaluated the feasibility of using the membrane filter field test laboratory to determine the bacteriological quality of the drinking water supplies in the national parks.

The many widely dispersed water supplies in the parks vary from small springs, infiltration systems, wells, or surface supplies to community-type systems. Although the conventional sanitary survey of any water supply system provides data on potential sources of contamination and general adequacy of treatment and distribution, routine examinations for bacteriological safety are needed. The results of such examinations also serve to guide the operation and provide a record which reflects the sanitary quality over an extended period.

Because of the relatively isolated location of many parks and their water supplies, it is often time consuming to collect and mail samples and await reports from State laboratories which may be several hundred miles away. Frequently, in the time between sample collection and examination, a change occurs in the character of the sample, and results may not always reflect the condition of the supply.

Mr. Hope is chief, General Engineering Program, Division of Sanitary Engineering Services, Public Health Service. Mr. Neill is a sanitary engineer in the Technical Services Section of the program.

Considering the relatively short season in many park areas, a method of performing a simple, rapid, field test to supplement regular laboratory examinations would be valuable.

The membrane filter technique was introduced into the United States from Europe in 1947. Considerable research has been conducted in the United States, including laboratory studies by the Robert A. Taft Sanitary Engineering Center of the Public Health Service, to develop the technique for the bacteriological examination of drinking water. The membrane filter procedure has been accepted as a tentative method in the 10th edition of Standard Methods for the Examination of Water, Sewage, and Industrial Wastes. Portable field test laboratories (MF kits) are available to run tests and obtain results in the field. The time required to obtain results with MF kits is approximately 18 to 20 hours as compared to 2 or 4 days, plus time in transit, with the standard dilution tube test.

Initiation of Studies

Although evidence (1) indicated that the MF field kit might be used effectively with national park water supplies, it was considered desirable to run a trial under actual field conditions. The National Park Service requested that the Public Health Service perform special studies relating to the applicability of the membrane filter technique. A project proposal of the work and objectives was outlined. Two duplicate studies of

than in men, and an undetermined number of the doubtfully positive tests in this survey may not have represented a past or present syphilitic infection. As previously mentioned, when in doubt we usually treated without attempting further examination.

The difference between the percentages of reactive reports in the white workers who were not actually migrants and the nonwhite migrants is striking, but it must be recognized that the mode of life and socioeconomic status of migrants are peculiarly conducive to venereal disease. The laborers follow the crops in many sections of the country. They comprise a moving army without benefit of the discipline and living conditions provided to most armies. Many have had little or no formal schooling. Yet, migrant laborers are still an indispensable part of our agricultural economy, and their health is of national concern.

That some progress has been made in the general reduction of the reservoir of infectious syphilis among migrants may be inferred from table 3. While the older ages have the higher rates of reactivity, it is also true that a greater proportion of those reactors had either already been adequately treated for their infection or at least had once been under the care of a physician and had received some treatment. These data may show some past accomplishments, but the great majority (over 70 percent) of the re-

actors in the younger age groups had no treatment for syphilis. If syphilis is to be controlled, case finding in the younger age groups is essential. Bringing these younger migrants with reactive test results to treatment was in itself justification of the survey.

Treatment for Gonorrhea

Due to the lack of privacy and also of time, male patients were not examined for urethral discharges in many of the camps. However, all migrants with such complaints or other illness were urged to report them. As a result, 95 males were treated with penicillin because of urethral discharges, and 24 female contacts of these patients were also treated.

Summary

Reports of serologic tests for syphilis were received for 5,021 nonwhite migrants. Of these, 812 (16.2 percent) had definitely positive tests, and 322 (6.4 percent) had doubtfully positive tests. Histories of adequate previous treatment were obtained from 236 of the patients with positive or doubtfully positive tests. Of 155 whites examined, only one had a definitely positive test report, and one had a doubtful report. A total of 770 patients received penicillin therapy for presumed syphilis and 119 were treated for presumed gonorrhea.

Tranquilizing Drug Research

The Public Health Service has established the Psychopharmacology Service Center in the National Institute of Mental Health, Bethesda, Md. The center will assist in the development of scientifically sound nationwide research on tranquilizing and other phrenotropic drugs used in the treatment of mental illness. Technical and research advisory services will be provided to scientists.

Dr. Jonathan O. Cole has been appointed psychiatrist in charge of the center. He received his psychiatric training at the Payne Whitney Clinic of the New York Hospital, New York City. Following 2 years' service as an Army psychiatrist, Dr. Cole joined the staff of the Division of Medical Sciences, National Research Council, Washington, D. C., where he worked with its committees on psychiatry and stress.

nel apparatus, and wetting of membrane cultures in petri dishes in the thermos bottles because of leakage of parafilm tape supplied with the kit.

One major difficulty, which persisted throughout the course of the studies, concerned the method of incubation of the membrane filter cultures. Thermos bottles supplied with the kits are used for incubation. Under low temperature conditions prevailing during the studies, a significant drop in temperature, as much as 20° F. 4 hours after starting the incubation of cultures, occurred in these thermos bottles.

Although the exact effects of such variation from required incubation temperatures were not evaluated, evidence indicated that the results were adversely affected. More recent improvements in MF kits also provide built-in electrically heated incubators that are adaptable to battery or to standard power sources.

As many of the individual tests were performed where the samples were obtained, open air conditions interfered with the use of the kit. Turbidities were abnormally high in the surface supplies during the early period of the studies because of the spring runoff. Because of the turbidity, difficulty in filtering enough water to obtain significant growth was reported from both study sites. Also, on some samples sediment deposited on the membrane so spread bacterial growth that coliform organisms could not be identified or counted.

The use of dehydrated nutrient media pads was considered convenient and satisfactory. However, possible inhibition of coliform growth related to the use of this nutrient method was suspected in the Rocky Mountain Park study.

Results of Parallel Tests

The determination of the agreement of the MF test with the standard dilution tube test was included in the studies. Temporary laboratory facilities and equipment to run the standard methods test were assembled in the parks. In addition, some samples were sent to State health department laboratories for examination.

Standard dilution tube tests were run on

Comparison of results of parallel membrane filter and standard dilution tube tests applying the 95 percent confidence limit to the MPN obtained by the standard dilution tube test

Park study area	Number of samples	Number of samples agreeing	Number of samples disagreeing	Percent agreement
Rocky Mountain----	69	56	13	81
Yosemite and Sequoia-----	54	50	4	93
Both studies----	123	106	17	86

approximately one-third of all samples collected for examination by the membrane filter technique. With the standard dilution tube method, an estimate of the most probable number (MPN) of coliform organisms is calculated, and test results are reported in coliforms per 100 ml. of sample. In the MF test, a direct count of coliforms on the membrane filter are made, and results are also reported per 100 ml. of sample.

In comparing the results of the two tests on the same sample of water, the 95 percent confidence limit was applied to the standard dilution tube test results in recognition of the bias in the standard method.

In the present studies, the coliform counts obtained by the MF test were generally lower than those obtained by the standard dilution tube test. In some cases, the lower counts were caused by excessive turbidity that limited the amount of sample that could be filtered as mentioned previously.

The results of only 17 of the 123 total parallel tests were in disagreement by the two methods (table). The number of results in disagreement was higher in the Rocky Mountain National Park study than at Yosemite and Sequoia-Kings National Parks. Considering the difficulties encountered, the agreement of the two methods is deemed satisfactory and indicates that the membrane filter test results are reliable.

Conclusions

1. The 86 percent agreement in the results obtained by the membrane filter technique and

approximately 6 weeks' duration were initiated in June 1955 in national parks. One study was conducted by John D. Eye, professor of sanitary engineering, Virginia Polytechnic Institute, in the Rocky Mountain National Park, Colo. The other study was conducted in the Yosemite and Sequoia-Kings National Parks, Calif., by Ely J. Weathersbee, instructor, Oregon State College. Both investigators, who are sanitary engineers, were called to temporary active duty from the Commissioned Reserve Corps of the Public Health Service.

In addition to studying the applicability of the membrane filter field test laboratory, they conducted sanitary surveys of water supplies sampled for examination by the MF kit. These surveys included inspections of the collection, treatment, and distribution systems of each water supply and a brief study of the drainage areas. In separate reports, the investigators have correlated the results of the bacteriological tests with the sanitary surveys.

Materials and Methods

The MF kit contains the necessary equipment for filtering and incubating the samples and sterilizing the funnel assembly in a rugged, portable carrying case which weighs 30 pounds fully loaded. Membrane filters and dehydrated nutrient media pads were used in the studies. Packs, each containing sufficient membranes and media for six tests, were purchased pre-sterilized in sealed polyethylene bags.

Additional items of equipment were found to be necessary for the tests. These included bottles for collecting water samples and storing sterilized dilution water, hand magnifying lens to assist in counting coliform colonies, improved plastic tape for sealing petri dishes prior to immersing in the thermos bottle incubators, and 95 percent ethyl alcohol for dipping the forceps tips prior to flaming.

The collection of samples and the examinations were conducted in accordance with the procedures outlined in the 10th edition of *Standard Methods for the Examination of Water, Sewage, and Industrial Wastes*. Parallel standard dilution tube tests were run on approximately one-third of all samples collected and results obtained by the two methods were

compared. The comparison was made to determine the degree of correlation of the MF kit field results with the standard dilution test results.

Briefly, the MF technique is to filter, under suction, a water sample portion through a small (2-inch diameter) circular, paper-thin disc composed of a cellulose material with pore openings of submicron size (1). Any bacteria present in the sample collect on the surface of the filter. The disc is transferred to a petri dish containing an absorbent pad with a small amount of nutrient broth culture media. A small quantity of sterile water is added to the petri dish which is then sealed and incubated in thermos bottles, provided in the MF kit, at approximate body temperature 37° C. After 18 or 20 hours, the dishes are removed from incubation, and those colonies exhibiting a metallic sheen, characteristic of coliform organisms, are counted. Results are recorded as the number of coliform organisms per 100 ml. of sample. Absence of coliforms indicates freedom from contamination.

Usually, in the Rocky Mountain National Park study, the MF kit was taken to the water sampling site where the test was performed. During inclement weather, the field laboratory was established in a ranger dormitory kitchen made available by the park superintendent. A home-type pressure cooker and a small electrically operated incubator were utilized for the standard dilution tube test and also for sample bottle sterilization. In Yosemite, the field laboratory was set up in the sewage treatment plant laboratory where a home-type pressure cooker was available for necessary sterilization of sample bottles, preparation of dilution tubes, and production of sterile water for use in rehydrating nutrient absorbent pads. Both investigators were assisted by park officials in locating water supplies and in obtaining the use of park equipment and facilities.

The MF kits, reputedly among the best available at the time of the studies, were ordered shortly before the initiation of the field work. Despite mechanical difficulties experienced with the MF kits early in the studies, the equipment performed in a satisfactory manner after adjustments. Most of the difficulties were related to ill-fitting petri dish holders, leakage of fun-

centration caused only partial inhibition of growth. The approximate mean colony count per tube in the control cultures was 300.

In the second test a stock solution containing 1 percent diamine, 1 percent sodium hydroxide, and 4 percent Triton X-100 in 60 percent isopropyl alcohol was diluted in distilled water to 1:1,000 and 1:5,000 diamine concentrations. Films were immersed for 10 minutes and were finally shaken in water before culturing. Growth inhibition was complete at the 1:1,000 dilution and two guinea pigs were negative for tuberculosis. At the 1:5,000 dilution growth inhibition was marked but incomplete and both guinea pigs were positive for tuberculosis. The approximate mean colony count per tube in the control cultures was 100.

These experiments illustrate the range in which diamine has caused complete inhibition by the dried sputum film technique, when weak sodium hydroxide was present either in the original diamine formulation or in the final diluting fluid. In the first experiment diamine proved definitely less effective when tested in the absence of sodium hydroxide.

Two representative experiments illustrating the whole sputum test technique are summarized. A tuberculous sputum pool, which yielded over 1,000 colonies per control slant, was used. Exposure to diamine was 30 minutes at 20° C.

In the first test diamine was diluted in water or in 0.1 percent sodium hydroxide from a 1 percent diamine, 10 percent isopropyl alcohol stock solution, and mixed with equal volumes of undiluted sputum. The final diluent before inoculating cultures and guinea pigs was water without sodium hydroxide but containing 1:6,000 potassium ricinoleate. Control sputum plus water contacted 1 percent sodium hydroxide in the final diluent to control contaminants before culturing.

A 1:625 final dilution of diamine without sodium hydroxide caused a moderate but not complete inhibition of *Mycobacterium tuberculosis*, and two guinea pigs were positive. However, it prevented all growth of contaminants. A 1:1,250 dilution also completely inhibited the contaminants but had no effect on the tubercle bacilli. A 1:2,500 diamine dilution no longer affected the contaminants.

When diamine was diluted in weak sodium hydroxide, it completely inhibited tubercle bacilli and contaminants at a 1:1,250 final dilution with two negative guinea pigs. At 1:2,500 it markedly but not completely inhibited *M. tuberculosis* and two guinea pigs were positive, but it still completely inhibited contaminants. Contaminants were no longer affected at 1:5,000.

In the second experiment (see table) final dilutions of 1:2, 1:10, and 1:50 of the same highly positive sputum contacted diamine which was diluted from a 2 percent diamine, 95 percent isopropyl alcohol stock solution throughout the test ranges with distilled water only. Before culturing, one portion of each diamine-sputum mixture was diluted 100 times in water containing 0.05 percent potassium ricinoleate. Cultures were inoculated 45 seconds later and duplicate cultures were made after the other portion of each mixture had been diluted in 0.05 percent potassium ricinoleate containing 1 percent sodium hydroxide. This technique in a whole sputum test minimizes the action of sodium hydroxide, save for its effect on contaminants. The sputum-water controls were cultured 45 seconds after dilution in 1 percent sodium hydroxide.

In the table the growth inhibiting capacity of

Whole sputum test with diamine (N-dodecyl-1, 3-propanediamine) using 3 sputum dilutions

Final sputum dilutions in test	Highest final diamine dilutions causing complete growth inhibition of			
	<i>Mycobacterium tuberculosis</i> —diluent before culturing contained		Sputum contaminants—diluent before culturing contained	
	No NaOH	1 percent NaOH	No NaOH	1 percent NaOH
1:2-----	1:250	1:500	1:1,000	² 1:2,000
1:10-----	1:1,000	1:1,000	1:4,000	² 1:32,000
1:50-----	1:4,000	1:4,000	1:16,000	² 1:64,000

¹ This final diamine dilution contained just under 20 percent by volume isopropyl alcohol which undoubtedly reinforced the 1:250 diamine action. The alcohol concentration in the other diamine dilutions is considered inconsequential.

² Not run at higher dilutions.

of such sputum, spread over 2 x 3 cm. rectangles on cover slips, were dried in the dark, generally at room temperature. Stained films from different pools showed from approximately 5 to more than 100 single acid-fast rods or small clumps per oil immersion field.

For the test, usually run in duplicate, a film was dropped into 40 ml. of diamine, held for the desired time at 20° C., quickly rinsed in 40 ml. of water to remove excess disinfectant or in a like volume of sodium ricinoleate to further neutralize some disinfectant (3), and then dropped into 40 ml. of water or weak sodium hydroxide containing glass beads. Hard shaking broke the cover slip and dispersed the film. This film-containing liquid was cultured on 3 slants, generally Loewenstein-Jensen medium, in 0.1 ml. volumes. Control films contacted water instead of diamine and were finally shaken in weak sodium hydroxide, before culturing, to inhibit the growth of contaminants. A maximum 0.25 percent of a film or 0.000125 ml. of original sputum was inoculated on each slant, which generally produced over 50 colonies in every control culture. Unfortunately diamine often dissolved rather large fractions of the films, so that culture inoculums tended to be below the stated maximum.

Guinea pigs were sometimes inoculated subcutaneously in parallel with cultures using volumes as large as 5 ml. or a maximum 12.5 percent of a film.

Whole Sputum Test

A measured volume of diamine (double the desired final concentration) was added to an equal volume of sputum, thoroughly shaken and held at 20° C. or room temperature for 30 minutes with intermittent agitation. It was then quickly diluted 100 times in water or weak sodium hydroxide and inoculated in 0.1 ml. volumes on culture slants. Guinea pigs were sometimes also given much larger subcutaneous inoculums. The final diluent sometimes contained small amounts of potassium ricinoleate which somewhat checked the action of diamine but had no demonstrable effect on the growth of tubercle bacilli. Control sputum plus water was finally diluted in 1 percent sodium hydroxide to control contaminants.

The advantages of this test were:

1. A known amount of sputum went completely through the test.
2. It was easy to run.
3. Four times as much original sputum (0.0005 ml.) was planted on each slant as the maximum culture inoculum (0.000125 ml.) in the dried sputum film test.

The disadvantage of the whole sputum test, apparently not a major one with diamine (3), was that 1 percent of the test dilution of disinfectant went through to the final culture.

Diamine on Concrete or Glass Surfaces

Two techniques were employed on concrete or glass surfaces. In one, 3 x 4 cm. rectangles on concrete or glass were contaminated with sputum which was allowed to dry. They were later covered with varying diamine dilutions. In the other, diamine was applied and allowed to dry and sputum was later placed over the same areas and allowed to dry. Care was always taken to keep the sputum boundaries within the diamine areas. These techniques were performed at room temperature. Sputum only was placed on control areas.

For the test a sterile swab was dipped into water or weak sodium hydroxide, rubbed over a rectangle and rinsed in the original fluid. This was repeated several times and cultures were then inoculated from the rinse fluid. Guinea pigs were also injected in one experiment. Control areas were swabbed with and rinsed in weak sodium hydroxide.

Results

A number of experiments with the dried sputum film technique pointed in the same direction. Two such tests are summarized. In the first test a 1 percent diamine stock solution in 50 percent isopropyl alcohol without sodium hydroxide was diluted in distilled water to 1:2,500 and 1:5,000 diamine concentrations. Films contacted these dilutions for 30 minutes. When films were shaken in 0.5 percent sodium hydroxide as the final diluent before culturing, 1:2,500 diamine caused complete growth inhibition and 1:5,000 produced marked but incomplete inhibition. When water was used as the final diluent, however, the 1:2,500 diamine con-

dilutions. The concrete rapidly absorbed most of the diamine before drying, but diamine concentrated on the glass surfaces by evaporation. The surfaces were stored in the dark at room temperature for 11 days, then like areas were prepared and allowed to dry for 4 hours. At this time sputum containing tremendous numbers of tubercle bacilli was diluted 10 times in water and placed in 0.05 ml. volumes on each treated area and on untreated control rectangles. The surfaces were stored overnight in the dark. Half of the treated surfaces were then swabbed 3 times and rinsed in 10 ml. of water and immediately inoculated on 3 cultures, while the other treated areas went through 0.5 percent sodium hydroxide before culturing. Some guinea pigs were inoculated from the concrete surface mixtures at the time that cultures were made. Half the control areas were treated with 0.5 percent and the remainder with 1 percent sodium hydroxide.

Control cultures from both glass and concrete developed over 200 colonies of *M. tuberculosis* per slant and many of these cultures from concrete also showed non-acid-fast contaminants.

None of the glass surfaces, including control areas, yielded growth of non-acid-fast contaminants. Cultures from glass areas on which sputum had been placed 4 hours after diamine were also all negative for *M. tuberculosis* through the 1:3,000, or highest diamine dilution.

When diamine had remained on glass for 11 days before sputum was added and the areas were swabbed and diluted with sodium hydroxide, growth of tubercle bacilli was completely inhibited by the 1:300 and 1:1,000 and almost completely inhibited by the 1:3,000 diamine dilutions. When water was used for final swabbing and dilution, complete growth inhibition was produced by only the 1:300 concentration of diamine. Dilutions of 1:1,000 and 1:3,000 caused marked and moderate degrees of inhibition, respectively.

Results of this test on concrete were disappointing. Probably insufficient volumes of diamine were applied, which mostly soaked into the concrete and was no longer available to contact the sputum.

Diamine on concrete in 1:300 concentration

for 4 hours completely inhibited growth on cultures and 4 guinea pigs were negative for tuberculosis. The 1:1,000 strength caused marked though not complete inhibition when swabbed and rinsed with sodium hydroxide but only moderate inhibition when treated with water.

Diamine on concrete for 11 days gave only a moderate degree of inhibition under both methods of final swabbing and dilution at 1:300, and 2 guinea pigs were positive for tuberculosis. No evidence of activity was apparent for the 1:1,000 concentration.

Toxic and Sensitizing Properties

A few preliminary tests on toxicity, skin irritability, and sensitizing properties of diamine were performed.

Intravenous injection of diamine into mice caused rapid death in a dose of 150 mg./kg., but 30 and 60 mg./kg. were tolerated and the mice appeared healthy 3 days later. Diamine was rather irritating by intraperitoneal injection, in doses as low as 40 mg./kg., into mice and killed all animals tested within 24 hours.

Two guinea pigs received 1 to 1.5 ml. of 1:300 diamine by stomach tube, lost weight for several days, and died. Another pig given a like volume of 1:1,000 diamine survived and gained weight for 2 months.

Diamine was not found to be unduly irritating to the skin in dilutions that might be used for practical disinfection. One volunteer rinsed his hands with 1 to 0.2 percent diamine many times for more than a year and has often allowed it to dry without any effect other than a slight tingling sensation. A 10 percent solution, allowed to dry on the forearm, produced a mild inflammatory reaction followed by slight desquamation.

Diamine is definitely irritating on intracutaneous injection. This was shown in two guinea pigs which, however, failed to develop measurable skin sensitivity to diamine under the following conditions. They first received 0.05 ml. intradermal diamine doses in 1:100, 1:300, 1:1,000, 1:3,000, and 1:10,000 dilutions. The 1:3,000 strength caused a minimal necrosis and this dose was repeated 3 times weekly until 9 such injections had been given. After a 19-day rest another 1:3,000 dose caused reac-

diamine against sputum is shown to be a function of the amount of sputum contacted by the germicide. This is a rigorous test considering the high content of organic matter and tubercle bacilli in this sputum. There were over 200 colonies per control tube for sputum diluted 50 times. Under practical conditions contamination with the quantity of tubercle bacilli represented by even the 1:50 dilution would be the exception.

The brief contact of the 1:2 and 1:10 sputum controls with 1 percent sodium hydroxide almost, but not completely, checked the growth of non-acid-fast organisms in cultures from these specimens (not shown in the table). The same contact for all diamine-treated sputums caused complete decontamination, which indicates that even the most dilute diamine employed had some effect on these extraneous organisms. This test again shows that diamine works more effectively against contaminants than against *M. tuberculosis* in sputum.

The effect of diamine on concrete surfaces was evaluated in three experiments. Fairly rough and absorbent concrete stepping stones were used. The pH of concrete, determined by swabbing areas with water and rinsing the swabs in the same water several times, approximated 9.0 in a number of tests, and these surfaces were also shown to have some buffer capacity. This should theoretically make concrete a favorable surface for decontamination by diamine.

The effect of sodium hydroxide was definitely exaggerated in the first two experiments, which is considered permissible because one can well use sodium hydroxide with diamine when disinfecting a concrete floor.

In the first experiment 0.2 ml. volumes of sputum were applied to the rectangles. Considerable sputum soaked into the concrete and drying was rapid. After the sputum had dried, 2 ml. of a turbid aqueous diamine suspension was flooded slowly over each rectangle during a 3-minute period. The diamine was spread evenly with a swab as it was applied. Much of it was absorbed by the concrete and the swab removed most of the excess. After 20 minutes a new swab was dipped into 40 ml. of 0.25 percent sodium hydroxide, the rectangle was swabbed, and the swab rinsed in the sodium hydroxide. This was performed 5 times and the

resultant mixture of diamine, sputum, and sodium hydroxide was left at room temperature until all areas had been treated and swabbed, then 6 cultures were inoculated from each mixture. Control areas were flooded with water instead of diamine and likewise swabbed into sodium hydroxide.

The test was run on duplicate concrete surfaces, and the cultures of control areas developed over 300 colonies per tube. The highest dilution of diamine that caused complete growth inhibition was 1:5,000 for one surface and 1:2,500 for the other. In the latter instance 1:5,000 diamine produced almost complete inhibition.

In the second experiment 1:500 and 1:5,000 aqueous diamine dilutions in 1.5 ml. volumes were slowly flooded on concrete rectangles and allowed to dry. Two hours later 0.05 ml. amounts of positive sputum were spread over the treated and control areas and were left overnight at room temperature. The test was completed on the next day as in the first experiment.

Control colonies approximated 50 per tube, but no growth appeared in cultures from the 1:500 and 1:5,000 diamine-treated rectangles. This experiment also contained tests with 1:500 diamine made up in half saturated urea and further diluted to 1:5,000 with water, and 1:500 diamine in 2 percent Clorox which was likewise further diluted. Urea favors diamine solution and, as dried urea is slightly deliquescent, it was thought that this mixture might be more effective than aqueous diamine only. This was not proved although diamine in urea also caused complete inhibition at 1:500 and 1:5,000 concentrations. The diamine-Clorox mixtures were incompatible and separated. Even the preparation of 1:500 diamine and 2 percent Clorox failed to cause complete inhibition of growth.

The last experiment was planned to test the residual action of diamine that had been dried for varying periods on concrete and glass surfaces and to minimize the effect of sodium hydroxide. Diamine was diluted in water, from a clear stock solution of 2 percent diamine in 99 percent isopropyl alcohol and 3 percent Triton X-100 to final concentrations of 1:300, 1:1,000, and 1:3,000. Rectangles on glass and concrete were flooded with 0.25 ml. to 0.4 ml. of these

action. It inhibits the growth of sputum contaminants more effectively than that of *Mycobacterium tuberculosis*. Its activity against bacterial spores, however, is not known.

Diamine does not appear to be an undue skin irritant. While no sensitizing ability was found, this possibility should be kept in mind. It appears promising as a surface disinfectant for tuberculosis hygiene and probably for more general sanitation also.

Record Number Rehabilitated

A record number of 66,273 handicapped persons were restored to productive employment through the State-Federal vocational rehabilitation program during the fiscal year ending June 30, 1956.

This was the highest total since the start of the public rehabilitation program in 1921 and was about 14 percent above the 57,981 rehabilitated in fiscal 1955.

The record figure includes 65,640 persons restored to employment directly through the State-Federal vocational rehabilitation program. The other 633 persons were placed in jobs through specific projects such as rehabilitation centers and shelter workshops developed jointly by community organizations and State rehabilitation agencies and financed, in part, by Federal grants.

Of the total rehabilitated last year, approximately 3,500 entered such "shortage" professional fields as education, medicine, and engineering. About 8,200 are in skilled trades, and approximately 6,200 work on farms. Most of the others are in managerial, sales, and service jobs or in unskilled work.

Roughly 13,000 of those rehabilitated had been dependent on public assistance immediately prior to or during the rehabilitation process and had been receiving approximately \$11.1 million a year in aid payments. The total cost of rehabilitating these people was \$9.2 million.

More than 48,000 of the rehabilitants were unemployed at the time they began receiving rehabilitation help, and most of the others were in unsafe, part-time, or otherwise unsuitable jobs or were in danger of losing their jobs because of disability.

tions indistinguishable from previous responses to this concentration (4).

Diamine Compared With Phenolic Disinfectants

Sputum film tests have been run in this laboratory on several phenolic disinfectants (5). Exposure of films to disinfectants was 30 minutes, and the final diluent contained 0.25 percent sodium hydroxide. The highest dilutions of three representative phenolic preparations that caused complete growth suppression were:

Liquor Cresolis Saponatus U.S.P. 1:200.

Lysol (Lehn & Fink Products Corp.) 1:200.

Amphyl (Lehn & Fink Products Corp.) 1:400.

As shown in the present report, 1:2,500 diamine produced complete growth inhibition under the same conditions excepting that the final diluent contained 0.5 percent sodium hydroxide.

Conclusions

Under natural conditions of contamination and infection, *Mycobacterium tuberculosis* is always accompanied by exudate. N-dodecyl-1,3-propanediamine (diamine) is shown to be an efficient disinfectant of tuberculous exudate. This is especially true when diamine is incorporated in weak sodium hydroxide. The evidence was developed by rigorous methods in which cultural results have been supported by animal infection tests.

Diamine has an even greater growth inhibiting power for sputum contaminants and also, from unreported experiments, for heavy concentrations of *Escherichia coli* and *Micrococcus pyogenes* var. *aureus*. Hence, it can be considered a growth inhibiting agent with a wide antibacterial action although its effectiveness against spore formers is not known.

The dried film and moist sputum testing procedures imitated the two varieties of contamination likely to occur. Each method has advantages and disadvantages. That the results using either technique were not far apart makes it possible to obtain the advantages of both. Thus, washing diamine from the film did not reduce its effectiveness, and the somewhat uncertain findings for film disinfection by

diamine plus sodium hydroxide were corroborated in the surer moist sputum technique.

The experiments with the use of diamine on contaminated surfaces, limited to concrete and glass, suggest that similar results might be expected for other smooth, inert, or alkaline surfaces.

It seems reasonable to employ the sodium hydroxide-containing preparation at a diamine dilution of 1:1,000 for heavily contaminated articles such as specimen bottles and emesis basins. For less heavily contaminated areas such as floors in the immediate vicinity of patients, bed frames, bedside tables, and laboratory surfaces, a dilution of 1:2,500 is suggested. A dilution of 1:5,000 would seem adequate for surfaces possibly, but not probably, contaminated, such as sanatorium and hospital floors and counters in general. A minimum contact period of 30 minutes is recommended.

If applications to fixed surfaces are not rinsed but allowed to dry in situ, an additional advantage should be gained. A smooth, inert, or alkaline surface mopped twice weekly should maintain a considerable disinfecting potential, especially if soap is not employed.

Sodium hydroxide should be incorporated with diamine unless the resultant alkalinity is contraindicated, in which case strengths from 1:250 to 1:1,000 are recommended.

Diamine is not recommended for the routine disinfection of sputum. The intimate mixing required for a sure effect would be entirely impractical. For extreme accidental contamination, such as the spilled content of a specimen bottle, the area should be flooded with concentrated diamine solution (1:200 approximately) containing sodium hydroxide, the disinfectant and the contaminating material should be mixed well and the entire area covered with newspapers or similar material for at least an hour.

Summary

The disinfectant action of N-dodecyl-1,3-propanediamine (diamine) against highly positive tuberculous sputum was evaluated in several ways. Its activity, particularly in the presence of sodium hydroxide, was high.

Diamine has a broad spectrum antibacterial

Death Certificate Statement of Occupation: Its Usefulness in Comparing Mortalities

By ROBERT BUECHLEY, M.A., JOHN E. DUNN, Jr., M.D., M.S.P.H.,
GEORGE LINDEN, M.P.H., and LESTER BRESLOW, M.D., M.P.H.

SEVERAL STUDIES have indicated occupational factors in the occurrence of various chronic diseases. One may cite "chimney sweep's cancer" (1), lung cancer among chromate workers (2), and, more recently, higher rates for coronary heart disease (3) among London bus drivers as compared with bus conductors.

It would seem possible that a comprehensive survey of the frequency of other diseases among all occupations as recorded on death certificates, relating these to the numbers of persons in the occupations enumerated by the census, would provide valuable epidemiological leads—that is, the formulation of hypotheses about the occupational origin of certain diseases.

Such studies would require much detail and accuracy, both in the coding of cause of death and in the coding of occupation. After more than a half century of codification and revision,

the International Statistical Classification of Diseases, Injuries, and Causes of Death has become a workable and consistent tool, with sufficient detail and sufficient accuracy for the purpose. This detail and accuracy has been achieved by querying causes of death that are ill defined or not understood and by a coding system that requires definite and unambiguous statements.

For the other axis of classification, occupation, two major coding systems have been developed in the United States since 1850: The Dictionary of Occupational Titles developed by and for the United States Employment Service and the system developed for the Bureau of the Census by Dr. Alba M. Edwards and others. These systems agree only in broad categories. Furthermore, the occupations reported on death certificates are not routinely coded and thus are not policed for completeness and accuracy as are reported causes of death. This has led to distrust of the accuracy of the occupation entries and to a natural reluctance to use the entries even in the search for epidemiological leads. Only by use, coding, and querying will occupation reporting increase in accuracy.

The only population base available by occupation for computation of rates is that provided by the decennial census enumeration. As we will point out, the definition for occupa-

which recommends the rules for death certificate entries, defines the "usual occupation" of an individual as "the job he pursued for the longest part of his working life" (6). This will be called the NOVS definition, and the occupation derived from it will be called "the usual occupation."

5. Finally, on a trial basis, this study uses another method of assigning individuals to occupations. Epidemiological considerations require that the occupation be pursued for a sufficiently long time so that the exposure to the occupational environment can be expected to initiate pathological processes. There is no single answer to "how long is long enough?" but 5 years is offered as an estimate for chronic conditions. Thus, any jobs held for a total of 5 years or more will be called "the exposure occupations." Any one individual, therefore, can, according to this definition, appear in more than one occupational category.

All the occupations and identifying industries worked in for 5 years or more were abstracted from the occupational history onto a 3" x 5" card. This was accomplished by using the 3-digit numerical codes for occupation and industry in the Census Bureau's "Alphabetical Index of Occupations and Industries" (7).

Three classes of occupations were determined from the occupational history. These were (a) the usual occupation, determined by the NOVS definition, (b) the last occupation, determined by the census method, and (c) all the exposure occupations (frequently more than one for each individual), determined by the exposure method. These chosen occupations were also entered on the 3" x 5" card. Industry identification was used only as an aid to coding the occupation.

After the occupation codes had been entered from the occupational history, the occupation and industry from the death certificate were copied verbatim onto the card and then coded according to the 3-digit numerical code. If the code numbers for occupation agreed with respect to all 3 digits, the agreement between occupational history and death certificate entry was considered perfect. Agreement failed, however, when the death certificate and occupational history entries did not agree in respect to all 3 digits.

The number of cases having 3-digit agreement by each of the three methods is shown.

	Cases
All three methods.....	141
Usual occupation and last occupation but not exposure occupation.....	0
Usual occupation and exposure occupation but not last occupation.....	14
Last occupation and exposure occupation but not usual occupation.....	45
Usual occupation only.....	0
Last occupation only.....	26
Exposure occupation only.....	11
No agreement.....	67
Total number of cases.....	304

The percentage agreement for the "usual occupation" method is 51.0

$$\frac{(141 + 14 = 155)}{304} = 51.0\%$$

For the "last occupation" method, it is 69.7

$$\frac{(141 + 45 + 26 = 212)}{304} = 69.7\%$$

For the "exposure" method it is 69.4

$$\frac{(141 + 45 + 14 + 11 = 211)}{304} = 69.4\%$$

The tabulation shows that there is a stable core of 141 persons (46.4 percent) with one and only one occupation determined on their occupational history, no matter which method is used. To this core are added special classes of persons to make up each total. Agreement in terms of usual occupation adds only 5 percent to this core. Last and exposure occupations show almost a 90 percent overlap, that is, the last occupation is usually held for 5 years. The highest percentage agreement is found with the last occupation method, a rather surprising result in view of the plain request for usual occupation on the death certificate.

Our finding indicates that to the people who furnish the information for entry on the death certificate "occupation" seems to mean current or present occupation. This finding appears to be true even if this last occupation is a short-time (less than 5 years) occupation, which tends to increase the number of last occupations reported correctly. The poor agreement of usual occupation apparently results from a tendency to ignore previous occupations if the last occupation has lasted several years.

tional classification on death certification and census enumeration are different. A major epidemiological consideration is the degree of agreement between these two entries in spite of the differences in definition.

Materials of the Study

The present study was undertaken by the bureau of chronic diseases, California State Health Department, to examine the errors resulting from the present, less than perfect, occupation reporting on death certificates. Though based on a chunk sample, the study offers evidence and conclusions which may be of some use. A recent investigation of lung cancer (4) made available life-long occupational data on certain persons. We took the opportunity to compare these data with death certificate statements of occupation for the same persons.

During 1949, 1950, and 1951, trained occupational analysts took complete occupational histories from 518 lung cancer patients and 518 control patients. The patients, ranging in age from 30 to 80 years, were located in university, county, private, and Federal hospitals. Patients in these hospitals came largely from the middle and working classes of the California population so that professional and managerial classes were under-represented. Since most of the hospitals were in urban areas, the farming population was also poorly represented.

The men in this group were followed through the death indexes of the California Department of Public Health for 1949 through 1952. Four hundred and twenty-three male deaths of all ages (mostly of the lung cancer cases) were found. A copy of the death certificate was obtained for each death and was attached to the occupational history form. Only the 304 males aged 35 to 64 were used for the balance of this study. Persons under 35 are often not "settled" in any occupation, and there are relatively few deaths from chronic disease occurring in this age range. Since persons 65 and over are frequently retired or have taken terminal occupations, only incomplete and less satisfactory population counts by occupation are available from the census enumeration for rate computations in this age group.

Assigning Occupational Categories

Before working out the problems in comparing death certificates and occupational histories when using closely specified occupations, it is necessary to know what is meant by occupation. Unfortunately, defining occupation is in itself a major problem. Besides the two coding systems noted, several assignment methods or definitions are used in various special fields. There is in addition the complete occupational history of the person concerned. For purposes of clarity, it seems desirable to list and explain the definitions and the five methods this study used for assigning individuals to occupation categories.

1. The entry of occupation on the death certificates often is the raw material in any study of death rates by occupations. Instructions in California and in most other States for entering occupations on death certificates are based on the model certificate proposed by the National Office of Vital Statistics of the Public Health Service. The actual entry, whether or not it is in accordance with these instructions, will be called "the death certificate occupation" or "the death certificate entry."

2. The complete occupational history of the person concerned is a chronological list and description of occupations and lengths of time spent at each. This information has been recorded for the limited group of persons in the present study. For the purposes of this investigation, it will be assumed that the listing is correct although some memory loss, and perhaps bias occurred. This list will be called "the occupational history."

3. The census method of assigning a person to an occupation is given in Bureau of the Census publications (5). It is an operational definition, derived from answers to the question, "What kind of work was he doing . . . at the job he held during the census week? . . . at the last job he held [if he were unemployed]?" In effect, then, the occupational populations derived from the census enumeration, to which the death certificate occupations need be related for the computing rates, are based on last occupation. This method will be called the census method, and the occupation derived from it will be called "the last occupation."

4. The National Office of Vital Statistics,

census code. This method resulted in 72 percent agreement on last occupation as against the 69.7 percent agreement with the 3-digit code. Further improvement in agreement, with loss of occupational precision, results from the use of 1-digit or social class code. This would give 76 percent agreement, as can be calculated from table 1. It does not appear that this increased agreement would be worth the loss of precision. In addition, these broad groupings are more socioeconomic than occupational, and thus exposures peculiar to specific occupations would be lost.

Another means by which agreement could be improved would be to code on environmental exposure, cutting across socioeconomic strata. This method would require groupings on the basis of similar exposure, such as grouping together "farmer" and "farm laborer," widely separated in the census system, or grouping together "aviator, army" and "aviator, commercial," also widely separated. Such a plan would entail development of a completely new coding system on exposure and would be entirely different from the approach with which this study

began. Hence, the 3-digit census codes are used as the basis of agreement or nonagreement for this study.

Accuracy of Reporting

Only a very few of the many individual occupations are present in sufficient numbers to be treated individually. Grouping these by broad socioeconomic groups, though admittedly not the ideal method, allows some estimates of the variability of reporting accuracy to be made.

Table 1 presents the death certificate occupation, as taken from the death certificate, in comparison with the last occupation, as taken from the occupational history. It attempts to give a concise report of the occupation shifts observed. Although occupations are grouped into the 10 socioeconomic groups used by the Bureau of the Census, it should be reemphasized that percent agreement is by detailed, 3-digit codes. The failures of agreement are of two kinds: upgrading and frank errors.

As evidence of errors of the first kind, the

Choosing the Method of Assignment

As indicated previously, the populations by occupation provided by census enumeration are based on last occupation. The validity of mortality rates by occupation, which are based on entries of occupation on death certificates on one hand and census enumerations on the other, is dependent on the degree to which death certificate entries represent last occupation. Fortunately for our purposes here, although in dis-

regard of instructions, death certificate entries are most apt to be last occupation and not usual or some other prior occupation. The remainder of our presentation, therefore, will be concerned only with the agreement between last occupation revealed by occupational history and that entered on the individual's corresponding death certificate.

We attempted to group occupations according to a 2-digit code rather than the 3-digit

group of lung cancer patients and controls and had obtained their occupational histories. To study the limitations inherent in the use of death certificates for occupational mortality studies, the occupation reported on the death certificate was later compared with the occupation reported in the interview. The study is based on a chunk sample, but it indicates the kind of results obtainable.

From comprehensive occupational histories, mostly of the lung cancer patients, 304 deceased men aged 35-64 were assigned to the 3-digit occupation codes used by the Bureau of the Census. A similar assignment of occupation codes was made for the occupations reported on the death certificates. Occupation was in agreement when the assigned 3-digit codes were identical. Out of a multiplicity of possible rules for assignment, three were applied to the occupational histories. These rules and the percentage agreements they generated are as follows:

"Usual occupation" method, the National Office of Vital Statistics rule—51.9 percent agreement.

"Last occupation" method, Bureau of the Census rule—69.7 percent agreement.

"Five-year exposure occupation" method, our own rule—69.4 percent agreement.

Despite a phrase on the death certificate defining usual occupation, the death certificate entries best represent last occupation. Because of this situation, because death rates must be computed by using death certificate populations for the numerator and census populations for the denominator, and because the denominator occupations are defined by the census rule for last occupation, we used the last occupation rule for the balance of the study.

By grouping occupations into 10 broad groups, though retaining 3-digit agreement, we obtained some idea of the variability of misreporting. Since it cannot be assumed that this variability is random, the specific net misreporting for each group must be used with caution. By considering the effects of positive association between a cause of death and an occupation, it seems evident that strong positive associations will show themselves despite considerable misreporting.

number of entries above and to the right of the diagonal in table 1 is larger than the number below and to the left. There is movement upward into professionals, managers, and craftsmen from operative and service occupations. Death certificates placed 45 persons in "higher" occupations, socioeconomically, than warranted, and placed only 21 in "lower" occupations.

Frank errors occur throughout table 1 in a somewhat random manner. They are also responsible for the anomaly of persons coded to the correct socioeconomic group but not to the correct occupation within the group, for example, an actor reported as an aviator or a painter reported as a carpenter. While social class is correct for these occupations, environmental exposures may be completely incorrect. Another feature is the variability between groups in proportion of agreement. This is further presented in table 2, which is a summary and extension of part of table 1.

Several comparisons between persons known from occupational history to have specific occupations and those designated with these specific occupations on death certificates are shown in table 2. Columns *a*, *b*, and *c* of the table indicate the order of magnitude of the error in the number of deaths attributed to an occupation compared with what this number should be. It is of some interest to know the numerical error in the numerator of a rate even though a portion of this number may include the wrong persons. The greatest error is for farmers and farm laborers, with over 80 percent excess in the former and 60 percent deficiency in the latter. The obvious explanation would seem to be the upgrading of farm laborers to farmers on death certification. This is partially true but, as can be seen in table 1, misreporting out of and into these categories is not quite that simple and direct. As might be expected, the professional category of occupations has the next highest excess, which is largely a result of upgrading on death certificates, as can be seen in table 1. The other occupational categories are considerably closer to their correct number, with only operatives and service workers deviating as much as 20-25 percent. The actual rates of mortality from death certificates for such categories as managers, clerks, salesper-

sons, and craftsmen will not be severely biased because of excessive or inadequate numbers of deaths attributed to the specific occupations in these categories.

Columns *d* and *e* in table 2 show that on the average about 70 percent of those persons designated on death certificates as having a specific occupation will actually have had the occupation. The range is from 45.5 percent for farmers to 81.8 percent for service workers. Column *f* of table 2 gives the percentage of those persons who have a specific occupation on their occupation history that is identically designated on their death certificates.

The essential proportions for anticipating and interpreting data from the use of occupation on death certificates in the search for abnormal risk of fatal disease are contained in columns *c* and *f* of table 2. Column *c* indicates the degree and direction of bias for mortality rates where, owing to misreporting, the percentage deviation from 100 is unrelated to occupation. For example, occupations in the professional category would be one-third excessive, operatives would be 23 percent deficient, and managers and clerks would be approximately correct. However, in the case of a specific occupation carrying an increased risk of disease, the excess deaths would be retained in the specific occupation on death certificates according to the proportions given in column *f*.

Conclusion and Summary

At the present it must be admitted that searching for increased risk of specific causes of mortality in specific occupations through death certificate occupational entries is a rather crude and somewhat insensitive method. However, those who are interested have an excellent chance of recognizing increased risks of the order of several fold by this approach. It is also likely that a significant increased risk, when found, will understate the true risk.

Analysis of death rates by cause and by detailed occupation may reveal useful relationships. Cause of death is fairly accurately reported while occupation, not at present being routinely coded or "policed," is less accurate. The bureau of chronic diseases of the California State Department of Health had interviewed a

tration medium at 0, 2, 4, and 6 hours. Separate tubes were employed for the penicillinase addition. Therefore, five tubes were used for each penicillin G concentration. The fifth tube was a control containing no penicillinase. The concentration of penicillinase used was sufficient to inhibit all concentrations of penicillin G used in this experiment and did not inhibit the growth of the organism when penicillin was absent or present.

Results and Discussion

Penicillin G inhibited the growth of *H. ducreyi* strain CH1A, at concentrations over 0.1 unit per milliliter of agar. Gram stains of cells of the 0.1-unit plates showed cells that were swollen and elongated to several times their normal size, which indicates that this concentration constitutes a sublethal dose (8). Growth was not inhibited, and subcultures of these organisms on nutrient blood agar without the drug resulted in normal appearing *H. ducreyi*. These results are shown in the following tabulation:

Penicillin G (units/ml. agar)	Type of cells
0-----	Normal chains.
.001-----	Do.
.01-----	Do.
.1-----	Swollen and elongated.
.2-----	No growth.
.3 to 20.0-----	Do.

Efforts to transfer normal and elongated cells to gradually increased amounts of the drug resulted in no detectable resistant organisms.

The results as shown in the following table indicate that inhibition is a relationship of concentration of penicillin G and the length of time *H. ducreyi* is in contact with the drug. Consequently, 0.1 unit of penicillin G per milliliter of casitone-saline medium did not inhibit growth after 24 hours; 0.2 units of penicillin G per milliliter of medium inhibited growth after 6 hours' contact; 0.3 units of penicillin G per milliliter of medium inhibited growth after 4 hours' contact; and concentrations of penicillin G of 0.4 units or more per milliliter of medium inhibited growth in less than 2 hours' contact.

In the liquid medium no swollen and elongated cells were observed at any concentration of the drug used.

Time at which concentrations of penicillin G inhibit growth of *Hemophilus ducreyi*, strain CH1A, grown in casitone-saline medium for 24 hours

+ indicates growth and no inhibition.
— indicates inhibition of growth.

All tubes were incubated an additional 24 hours and were read, with no changes in the results. Wetherbee and co-workers (2) cultured *H. ducreyi* in tryptose phosphate serum broth with various concentrations of penicillin G and subcultured the organism 24 and 48 hours on chocolate tryptose agar plates. They found that penicillin G inhibited at 0.1 to 0.5 units per milliliter at 24 hours but that there was less inhibition at 48 hours. This suggested to Wetherbee that penicillin prolongs the lag phase but is not significantly bacteriostatic. While Wetherbee and his associates did not demonstrate any significant bacteriostatic effect of penicillin G upon *H. ducreyi*, our results indicate actual bacteriostatic and bactericidal effects based upon concentration of the penicillin G and the length of time the drug had to act upon the organisms. In our laboratory, avirulent strains of *H. ducreyi* showed different sensitivities to penicillin G and other antibiotics than did *H. ducreyi*, strain CH1A, or other virulent strains. Therefore, it seems probable that the strains Wetherbee and co-workers used were avirulent.

Eagle (9) states that penicillin G is inactivated by serum in vitro. Our experiments showed that 5-percent rabbit serum did not inhibit the effect of penicillin G upon the organisms. This, of course, may be more apparent

Effects of Penicillin G

In Vitro

On *Hemophilus ducreyi*

By SOLOMON SINGER, M.S.,
and WILBUR E. DEACON, Ph.D.

DURING the course of experiments at the Venereal Disease Research Laboratory on the treatment and prophylaxis of chancroid induced in human volunteers (1) and in animals, it was observed that therapy with oral penicillin G (Bicillin) did not aid recovery.

Previous reports have indicated *Hemophilus ducreyi* to be sensitive to penicillin in vitro (2-4) while in vivo experiments have demonstrated equivocal findings.

Deacon and associates (1), trying to confirm Willcox's theory that penicillin might be of value if given in such a manner as to produce and maintain high serum concentrations (5), found that penicillin G administered orally in five chancroid infected volunteers produced mean serum levels of only 0.025 penicillin G units per milliliter of serum. This concentration was not effective as a prophylactic agent for *H. ducreyi* infections. Treatment with orally administered penicillin V in five volunteers, however, resulted in a mean serum level of 0.232 penicillin G units per milliliter of serum, and lesions were definitely controlled during this treatment. Furthermore, if penicillin V was administered orally prior to inoculation with *H. ducreyi*, levels of penicillin G units per milliliter of serum reached a mean level of 0.492, and the volunteers either failed to develop lesions or developed very few lesions.

Mr. Singer is a bacteriologist and Dr. Deacon is chief, Microbiology Research, at the Public Health Service Venereal Disease Research Laboratory, Chamblee, Ga. Their work was supported in part by the Medical Research and Development Board, Office of the Surgeon General, U. S. Department of the Army.

In an effort to correlate Deacon's findings with in vitro results, the present study was undertaken. Our purpose was to determine the concentrations at which penicillin G inhibited the growth of *H. ducreyi* and the length of time at which concentrations of penicillin G inhibited growth.

Materials and Methods

Inoculum for all experiments was prepared by inoculating 5 ml. of casitone-saline medium (6) (1 percent Difco bacto casitone, 0.85 percent NaCl, plus 5 percent sterile rabbit serum), contained in 150 mm. x 20 mm. screw-cap test tubes (Kimble No. 45066), with a loopful of 24-hour *H. ducreyi*, strain CH1A (7), which is representative of virulent strains in our laboratory, grown in the same medium. Incubation of these cultures was at 34° C. for 16 to 24 hours. At the end of the incubation period, cultures were checked for purity by means of a Gram stain and subculture upon nutrient blood agar (7) (Difco nutrient agar 1.5 percent plus 5 percent defibrinated rabbit blood) plates. These plates were incubated at 34° C. in candle jars for 48 hours. The culture used as the inoculum was the same as used by Deacon and co-workers (1), had been checked previously for its ability to produce typical lesions in volunteers (1), was of known pathogenicity, and during manipulation did not lose pathogenicity.

To determine the concentration at which penicillin G inhibits the growth of *H. ducreyi*, nutrient blood agar plates containing concentrations of penicillin G from 0 to 20 units per milliliter of agar were inoculated with 0.5 ml. inoculum and the surface of the agar spread with sterile bent glass rods. These plates were incubated at 34° C. in candle jars for 48 hours. Colonies were observed, and Gram stains were made in order to observe morphology.

It was also desired to determine the length of time at which concentrations of penicillin G inhibited growth. Screw-capped test tubes, 150 mm. x 20 mm., with 10 ml. of casitone-saline medium and containing graded amounts of penicillin G were inoculated with a loopful of the *H. ducreyi* culture. One milliliter of 1,000 units of Difco bacto-penase (penicillinase) was added to each tube of each penicillin G concen-

Disability in Butler County, Pennsylvania

By SAXON GRAHAM, Ph.D.

THE EXTENT of disability in a large population, conceived as individual inability to behave adequately in consequence of disease or injury, has received relatively little investigation.

A definition of adequate behavior should perhaps be a philosophical one. But for the purpose of measurement, we may discern forms of behavior which are attributable to a physiological handicap. For example, disease or injury may contribute to breakdowns in the interpersonal relations between the individual and members of his family. It may prevent him from carrying on his usual occupation. It may force him into restrictions of diet. It may result in motor disabilities, which are the forms with which this paper is concerned. These include the inability of the individual to feed himself, to dress and groom himself, to walk without help, and to climb or descend stairs, and the necessity of being confined to the house or bed or of having to use a wheelchair or a crutch or cane to walk.

Such disabilities present a much more tangible problem to the community than illness per se. Illnesses are important to society mainly because of their potential for causing either death or disability. It is the death or disability resulting from illness or injury, rather than

the illness itself, which creates the burden of expense and the loss of productivity.

In 1954, we attempted to assess motor disability, as we have described it, in Butler County, Pa. We investigated the extent and duration of motor disability in the population and the frequency of various kinds of disability. Also, we attempted to associate a specific disease or injury with each disability.

Method of Inquiry

The data for this inquiry were obtained as part of comprehensive health studies in Butler County. They are based on a probability sample of 3,403 residents. The sample allowed for geographic stratification and the proportionate representation of urban, rural place, and open country population.

Butler County is directly north of Allegheny County, which includes Pittsburgh. Of its total population of about 103,000, 28.1 percent live in cities; 19.4 percent, in rural places; and the remaining 52.5 percent, in open country. Ethnically, the population is relatively homogeneous, an American mixture of people with European ancestry. There is a smaller proportion of foreign-born residents than would be expected on the basis of national statistics. Housing and sanitation present few, if any, serious trouble spots.

Interviewing, editing, and coding were carried on during the summer of 1954. Interviewing was conducted by women. They spoke with only one member of each household, who was requested to report on the conditions of all other members. Questions were asked regarding chronic disease, physical impairments, acute

Dr. Graham, assistant professor of medical sociology, department of biostatistics, University of Pittsburgh, is director of the Butler County health studies. These studies were initiated to examine the impact of the newly established county health department on the population of the county.

than real. Some of the penicillin G may have been bound by some component of the serum, but the bactericidal effect is there, nevertheless.

Consequently, the sensitivity of this organism to penicillin G is an expression of the amounts which must be present in the medium in order to effect a binding with some cell constituent or constituents. Eagle and co-workers (10) interpret the binding of penicillin by bacteria to be determined by a single essential component, which is functionally inactivated by that combination which is normally present in significant excess. Schepartz and Johnson (11) propose that "binding occurs by cleavage of the beta lactam ring of penicillin and combination of the carbonyl or imino group of that ring with the binding component."

Our in vitro results can be compared with the in vivo results of Deacon and co-workers (1) in that, if the serum level of penicillin G is about 0.2 units per milliliter, that concentration should be sufficient to inhibit growth of *H. ducreyi*, strain CH1A, less than 24 hours after the patient's blood has attained this penicillin level. More immediate response would be expected if 0.3 or 0.4 units of penicillin G per milliliter of blood could be attained. Eagle and associates (12) state that the therapeutic action of penicillin is in a large part measured by the aggregate time for which it remains at effective levels at the focus of infection, that these effective levels in vivo are of the same order of magnitude as those effective in vitro, and that the effective penicillin time in the serum is usually a reasonable approximation of the penicillin time in tissue fluids.

While penicillin G can inhibit the growth of *H. ducreyi* in vitro, Deacon and co-workers (1) have shown that the serum penicillin G level does not attain the necessary concentration. Penicillin V, however, by increasing the serum penicillin G level, shows some usefulness in treatment of chancroid.

Summary

Penicillin G is bactericidal for *Hemophilus ducreyi*, strain CH1A, at concentrations over 0.1 unit per milliliter of medium. Inhibition of growth is dependent upon the concentration of the drug and the length of time at which the organism is in contact with the penicillin G.

A blood level of 0.3 or 0.4 units of penicillin G per milliliter should inhibit the growth of virulent *H. ducreyi* in 2 to 6 hours, and a level of 0.2 units of penicillin G per milliliter should inhibit the growth of this organism in less than 24 hours.

uals over many years, not to mention the fact that the community has had to support some of them, adds up to an important economic handicap.

The age and sex distribution of the 54 persons having disabilities, shown in figure 1, indicates that as age increases the proportion of persons disabled increases in rapid fashion, particularly among females. The rate of 2.6 per 1,000 for females under 25 years of age was about the same as the rate for males in this age group. However, for persons 65 and over, the female rate had increased to about 140 per 1,000, whereas the male rate had increased to only about 50 per 1,000. In every age group except the under-25-years one, more women than men were disabled. We must caution, of course, that here we are dealing with characteristics which appear relatively infrequently in the population. Estimates for prevalence by sex in the younger age groups have large relative standard deviations. However, estimates for the older age groups are more reliable, and the consistency of findings relative to sex in all age groups indicates a higher prevalence among females.

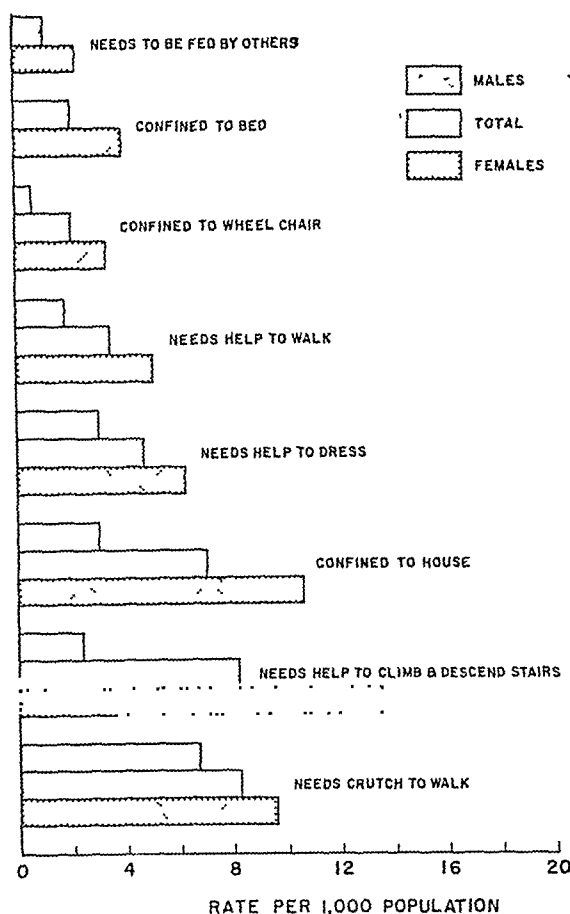

Types of Disability

Figure 2 shows the prevalence of various types of motor disability. The least frequent condition was having to be fed by another person. No males were in this category. The rate for females was 2.3 per 1,000; for all persons, it was 1.2 per 1,000.

Slightly higher was the prevalence of having to use a wheel chair; 2.1 persons per 1,000 were so incapacitated. Here again, most of the cases were found among females. Their rate of 3.4 per 1,000 was 5 times the rate for males. The rate for being confined to bed was also 2.1, and this disability existed exclusively among females.

Rates for the other disabilities increased from 3.5 for needing help to walk, to 4.7 for needing aid to dress, to 7.1 for being confined to the house, to 8.2 for having to use a crutch or cane to walk and for needing assistance in climbing or descending stairs. For every disability, the rate was higher for females than for males. The greatest difference between males and females was found for the inability to climb or

Figure 2. Prevalence of various motor disabilities, by sex, Butler County, Pa.

descend stairs without help. Here the rate for males was 2.5 per 1,000, and that for females, 13.6. The smallest differences between the sexes were found for the inability to dress without help and the need to use a crutch or cane to walk. For the former, the male rate was 3.1 and the female rate was 6.2; for the latter, the male rate was 6.7 and the female rate was 9.6. Again, these estimates have high relative standard deviations, and the magnitude of the rates should be interpreted with caution.

Causes of Disability

As shown in figure 3, conditions of the skin, bones, and organs of movement were mentioned as contributing to 30.2 percent of the disabilities. These conditions included pemphigus and especially arthritis. Injuries resulting from accidents were next most important, accounting

disorders, maternal and child health, nutrition, disabilities, sanitation, and sociological characteristics relevant to health. Specific queries were put as to whether individuals in the households in the sample had any of the motor disabilities mentioned above. When a positive answer was given, questions were asked as to the medical condition responsible for the disabilities.

Caution must be observed in the interpretation of the findings of this survey. It was impossible, for example, to determine the accuracy of statements interviewees made as to the medical reasons for the disabilities. Also, since only one member of the household was interviewed, there was no way of knowing for certain the actual status of anyone except that member. Nevertheless, comparison of the survey findings with those of the United States census of 1950 reveal close agreement on such nonmedical factors as the total number of persons in the county; the age and sex distributions of the population; the proportions of residents in open country, rural place, and urban areas; and the proportions having various amounts of education.

Estimated relative sampling errors for the more important statistics obtained in the health studies were as follows: a range of 3.7 to 7.7 percent for estimates of the numbers of persons in different age groups, 5.2 percent for the estimate of the number hospitalized in the year preceding the survey, and 13.2 percent for the estimate of the number of persons disabled.

Prevalence of Disability

Because of the lack of comparable data on disability in other areas, it is difficult to assess the situation in Butler County. Nevertheless, the number of people disabled, the proportion of households affected, and the duration of the disabilities found indicate that the problem is substantial.

Of the 3,403 persons in the sample, 54 had disabilities of the kinds investigated in the survey, a rate of 15.9 disabled persons per 1,000 population. These 54 people were afflicted with a total of 128 disabilities. The rate for persons with but one disability was 6.2 per 1,000 population; for those with 2 or more disabilities, it was

Figure 1. Age and sex distribution of persons having one or more motor disabilities, Butler County, Pa.

9.7. Of the 54 disabled persons, 61.1 percent had more than one disability. In sum, the prevalence rate for the disabilities examined in this study was 37.6 per 1,000 population.

The effects of disability, of course, are not confined to the individual who has it. They influence the whole family. Results of this study showed that a substantial proportion of the households in the county, 5.4 percent, had disabled persons among their members. One disabled person was found in 5.1 percent of the households, and 2 or more in 0.3 percent.

Another method of measuring disability is by its duration. If we sum the number of years each disabled person was unable to function optimally, we find that at the time of the survey 141.4 man-years per 1,000 population had been lost because of disability. About 1 person per 1,000 had been disabled 30 to 36 years. Almost 2 per 1,000 had been disabled 20 to 25 years, and about the same number had been disabled 10 to 15 years. The largest number, 6.2 per 1,000, had been disabled less than 5 years. The loss of the services of these disabled individ-

Comparison of the prevalence and distribution of antibodies to *Toxoplasma gondii* in an urban and a rural population suggests that factors responsible for transmission of human toxoplasmosis are common to both groups.

Distribution of *Toxoplasma* Antibodies in Comparable Urban and Rural Groups

By COLVIN L. GIBSON, Ph.D.

ONE of the major gaps in our knowledge of human toxoplasmosis is the means by which man comes into contact with, and becomes infected by, the causative agent, *Toxoplasma gondii*. Numerous studies in various parts of the world have made it clear that serum antibodies to *T. gondii* are widely prevalent in humans, suggesting that infection is relatively common although frequently inapparent, but little information has been published regarding the environmental factors which may contribute to the spread of this infection.

A recent study by the author and his colleagues of a rural Negro population near Memphis, Tenn., gave a clear picture of the distribution of *Toxoplasma* antibodies in that particular group (1). It showed that the prevalence of antibodies is about the same in both sexes; that the titers fall into a bimodal distribution suggestive of a nonspecific reaction at the lowest titers; that the chance of finding

antibodies increases with age; and that young people tend to have higher titers than older people.

That study, however, did not allow us to pinpoint any of the factors that might be working to produce such a distribution of titers. Nor did it permit us fruitfully to compare that population with any other group. The present study was therefore undertaken to attack the question of environmental factors in the transmission of toxoplasmosis by comparing the antibody status of the rural Negro population with that of a comparable urban group.

Methods

Figure 1 shows the geographic region in which this study was made. The urban sample consisted of 627 serums taken at random from the students of a large junior-senior high school in the city of Memphis. The students, all Negroes, ranged in age from 11 through 19 years. The rural sample consisted of 445 serums from persons in the same age group, also Negroes, taken at random throughout Fayette County, but chiefly from the area south of the Wolf River, which is shown shaded on the map.

Most of the serums from the rural population which we tested in the present study were included in the larger rural sample, represent-

Dr. Gibson is a parasitologist with the Section on Epidemiology, Laboratory of Tropical Diseases, National Institute of Allergy and Infectious Diseases, Public Health Service. He is currently located at the University of Tennessee College of Medicine, Memphis.

Figure 3. Medical conditions contributing to motor disabilities, Butler County, Pa.

for 17.1 percent of the disabilities. A large proportion, 13.2 percent, were attributed to conditions involving the circulatory system, particularly heart disease. Seven percent were caused by diseases of the nervous system, and the same percentage, by blindness. Diabetes was responsible for 6.2 percent of the disabilities, and congenital malformations, for 5.4 percent.

Twenty-four different types of medical conditions were cited as contributing to the motor disabilities. These conditions were mentioned as contributing to 128 disabilities in 54 disabled persons. Thus, a given medical problem in an individual caused, on the average, more than 2 motor disabilities. Four persons mentioned heart disease as causing them a total of 10 different motor disabilities. Arthritis was cited by 14 persons as contributing to a total of 26 disabling afflictions.

Summary and Conclusions

As public health scientists increasingly concern themselves with social well-being in addition to physical health, their interests will be focused more and more on problems such as the problem of disability. Disease in itself is a problem, but it is a liability to society mainly

when it causes a disability of one sort or another. When disability is defined as the inability of the individual to function adequately as a member of society, it immediately becomes a matter of first concern to public health.

The study in Butler County, Pa., based on a probability sample of 3,403 residents, gives some idea of the extent of motor disability. It was found that 15.9 persons per 1,000 population were afflicted and that more than 5 percent of the households had at least one disabled member. Disability was found more frequently among women than among men and more frequently among persons over 60 years of age than among younger persons. The disabilities of highest prevalence were the need for help in climbing or descending stairs and the need to use a crutch or cane to walk, each with a rate of 8.2 per 1,000. Next came being confined to the house (7.1), needing help to dress (4.7), requiring aid in walking (3.5), having to use a wheelchair (2.1), and being confined to bed (2.1). Having to be fed by another person was the least prevalent of the disabilities studied.

Among the medical causes of these disabilities, arthritis, injuries, and heart disease were prominent. Disabilities were typically of long duration, with one-third of the disabled population functioning less than optimally for from 10 to 36 years prior to the survey. The rate of man-years lost from optimal functioning because of disability was 141.4 per 1,000 population.

Undoubtedly, these figures underestimate the prevalence of disability, for they include only the disabled persons present in the households at the time of the interview. They do not include individuals who are disabled and living in institutions. For this and other reasons, caution must be exercised in interpreting the findings on disability in Butler County.

The Butler County study constituted an exploration of a subject about which we have little quantitative information. Apparently, the problem of disability is not negligible. Before we can assess it properly, we require better data on its magnitude, on the social and physiological factors which figure in its etiology, and on its costs to society in loss of production power and long-term expenditures for medical care.

Distribution of serums positive for *Toxoplasma* antibodies by titer for urban and rural populations in Tennessee

percent) had undiluted positive titers as contrasted with 23 of the 329 females (7.0 percent).

The difference between these rates is highly significant statistically ($P = 0.005$), but at present we cannot offer an explanation for this difference. A similar trend can be detected in the rural sample, in which 6 out of 231 males (2.6 percent) and 11 out of 214 females (5.1 percent) had undiluted positive serums, but the difference here is not statistically significant ($P = 0.16$).

Both the urban and the rural populations showed a distinct bimodal distribution of titers, with an unexpectedly large number of serums positive at the undiluted level. This distribution is illustrated graphically for all ages combined in figure 3. The large number of undiluted positives is consistent with the hypothesis of a nonspecific reaction, but we do not know what significance, if any, these low titers have in the epidemiology of toxoplasmosis.

The upper modal titer for the urban popula-

tion falls at a dilution of 1:16, while the upper modal titer for the rural group is 1:64. This shift cannot be related to age, since both groups include persons from 11 through 19 years, and analysis of the individual age samples does not reveal any trend in this direction. To determine whether the shift of modal titer actually is significant, we tested the data by the chi-square method. For this purpose, the positive serums were divided into two groups, those positive at a dilution of 1:16 or lower and those positive at a dilution of 1:64 or higher. The probability value derived from this calculation is slightly more than 0.05, suggesting that the shift in modal titer between the urban and the rural group may not be significant.

An entirely different picture is obtained, however, when we group together those serums having titers of 1:256 or higher as opposed to those positive at a dilution of 1:64 or lower. With this grouping, the probability value is only 0.009, indicating that the difference between the

Figure 1. Location of urban and rural populations from which serums were collected. The urban sample was composed of Memphis residents; the rural sample, of Fayette County residents, chiefly those in the area south of the Wolf River.

ing 987 persons of all ages, analyzed in a previous report (1). In order to relate the present study of a restricted age group to the overall prevalence in rural Fayette County, we show in figure 2 the prevalence rates for all ages, as previously reported. Rates reported for other parts of the world by various investigators are also included for purposes of comparison. In general, the antibody prevalence in rural Fayette County was greater than the level found in England (2) but less than that found in the Netherlands (3), in Germany (4), and in Austria (5). In the present report we shall be concerned only with the small portion of the curve from 11 through 19 years of age.

All the serums in both our samples were tested by the Sabin-Feldman dye test. The technique originally described by these investigators, including inactivation at 56° C. for 30 minutes, was used (6). Serums were tested undiluted and at progressive fourfold dilutions (1:4, 1:16, 1:64, and so forth) until the end point was reached. Frequent comparative tests on unknown serums by our laboratory and several other research laboratories in the United States have always shown good agreement, a fact which lends confidence to our results.

Results

The results obtained by the dye test for each of the sample populations are summarized in the table.

The prevalence of positive serums was 20.1 ± 2.3 percent for urban males and 20.7 ± 2.2 percent for urban females. Comparable rates for the rural group were 19.9 ± 2.6 percent for males and 17.8 ± 2.6 percent for females. Statistical analysis indicated that the slight differences in overall prevalence of positive serums between males and females in each population were not significant. (*P* values were 0.85 and 0.58 for the urban and rural groups, respectively.) Even when an analysis was made of each 1-year age group, no significant difference between the sexes could be detected. The greatest divergence occurred in the 11-year-old rural group, in which 24.3 percent of 37 males and 9.1 percent of 33 females were positive. Statistical analysis of these data using the formula

$$\sigma_a = \sqrt{(p \times q) / N_1 + (p \times q) / N_2}$$

gave a probability value of 0.09, which indicates that the observed difference between the sexes in this group probably is not significant. Since we failed to find a significant difference between males and females with respect to the prevalence of positive titers, data for the sexes were combined in all later calculations unless otherwise indicated.

One possible exception should be noted to the conclusion that there is no significant difference between males and females with regard to the prevalence of positive serums. For serums positive at the undiluted level, there was a highly suggestive difference between the sexes in the urban sample. Only 7 of 298 males (2.3

Figure 2. Prevalence of *Toxoplasma* antibodies by age, as reported for various parts of the world (1-5). Figures in parentheses show number of serums tested.

positive serums; that, although there is a difference in the upper modal titer between the two groups, it probably is not significant; that the rural group shows an unexplained tendency to produce titers of 1:256 or higher; and that the prevalence of positive titers is essentially similar in the urban and rural populations, both when all titers are considered together and when only titers of 1:16 or higher are considered.

The similarity between the urban and rural populations suggests that the factors responsible for transmission of human toxoplasmosis are common to both environments rather than being peculiar to one or the other.

Dental Manpower Resources

The demand for dental care is expected to increase more rapidly than the number of practicing dentists and dental hygienists in 11 western States.

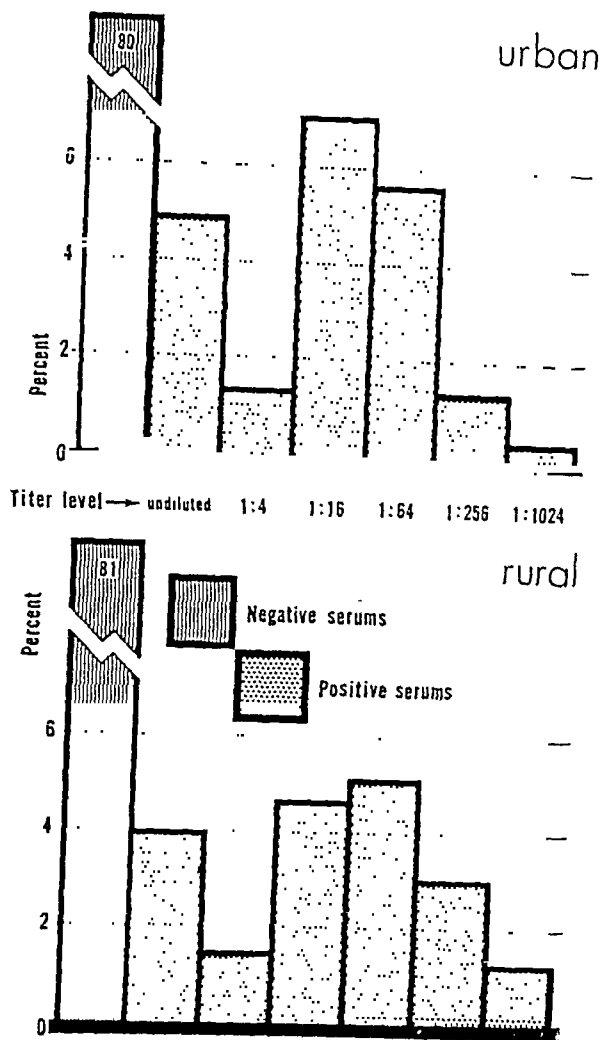

Of the 95,000 dentists who are expected to be practicing in the United States by 1975, about 16,000 will be located in the west. This would be an increase of 4,000 over the number practicing in the region during 1955, but still it would be 5,000 short of the number needed to maintain supply at the current level. It will be roughly 20,000 under the number required to meet the higher per capita demands for care which are expected at the end of the 20-year period.

Currently, western schools are graduating only 400 dentists annually. To meet demand, they must graduate an average of 1,600 a year between 1960 and 1975.

Dental hygienists must also be trained in greater numbers. Additional training programs are needed in junior and 4-year colleges. The west needs approximately 800 dental hygiene graduates a year, compared with the fewer than 70 now being supplied.

These requirements are stated in "Dental Manpower Requirements in the West," a survey covering Arizona, California, Colorado, Idaho, Montana, Nevada, New Mexico, Oregon, Utah, Washington, and Wyoming. The survey was undertaken at the request of the Western Interstate Commission for Higher Education and was conducted by the Division of Dental Resources, Public Health Service, in cooperation with the American Dental Association and the W. K. Kellogg Foundation.

Figure 3. Distribution of all serums tested, by titer, showing bimodality and shift of upper modal titer.

two populations is of considerable significance. Thus the rural population shows a strong tendency to produce high titers, but we do not know what the significance or cause of this tendency may be.

For both sexes and all ages combined, 20.4 ± 1.6 percent of the 627 serums tested from the urban group were positive (all titers), as compared with 18.9 ± 1.9 percent of the 445 serums from the rural group. Somewhat lower rates are obtained when only titers of 1:16 or higher are considered positive, on the assumption that the lower titers may represent nonspecific reactions in accordance with the bimodal distribu-

tion of titers which we previously mentioned. The rates in this case are 14.2 ± 1.4 percent for the urban sample and 13.7 ± 1.6 for the rural group. But whether we consider all titers or only those of 1:16 or higher, the numerical difference between the urban and rural rates is small, and statistical analysis verifies that it is merely a reflection of sampling variation. The probability values are 0.48 for all titers and 0.76 for titers of 1:16 or higher. Thus it is clear that there is no significant difference in prevalence of antibodies between the urban and rural populations of our study.

Conclusions

The examination of serums from comparable urban and rural Negro populations in Tennessee has shown that the two groups are essentially the same with respect to the prevalence and titer distribution of antitoxoplasmic antibodies. If we accept the presence of these antibodies as an indication of previous infection with *T. gondii*, then we must conclude that, at least insofar as the populations which we studied are concerned, persons living in urban or rural environments have an equal chance of becoming infected with this parasite. (For a discussion of the specificity of these antibodies, see reference 1.) From the epidemiological standpoint, this means that for an explanation of the transmission of this infection we probably must look not to factors associated primarily with one environment or the other but rather to factors common to both. Elucidation of these factors should be the goal of future research in this field.

Summary

With the Sabin-Feldman dye test, 627 serums from an urban Negro population and 445 serums from a comparable rural population were tested for antitoxoplasmic antibodies. All persons tested were 11 to 19 years old.

Analysis of the results with respect to the prevalence and distribution of titers showed that there is no difference between the sexes at any age; that the titers have a bimodal distribution in both the urban and rural groups, with an abnormally large number of undiluted

Available methods for isolating, identifying, and tracing to their sources of origin the organic chemicals polluting our water supply are reviewed.

Organic Contaminants Affecting the Quality of Water

By F. M. MIDDLETON, B.S., M.P.H., and A. A. ROSEN, Ph.D.

TODAY'S vast chemical industry and particularly its giant offspring, the production of synthetic organic chemicals, have introduced new problems to scientists engaged in providing and protecting the Nation's supply of pure water. By one route or another, these chemicals or the waste products resulting from their manufacture enter the natural environment and affect the water adversely not only for the householder but even for further industrial use. Many of the products, particularly the synthetics, were unheard of a few years ago. Recent and estimated production rates of several of these chemicals are shown in table 1 (1, 2).

Industrial contamination of water, while important, is not the only factor to consider in the complex organic pollution situation. Domestic sewage, natural run-off, and materials derived from the life cycle of aquatic plants and animals contribute substantial quantities of organic materials to streams. Increased supplies of phosphorus and nitrogen from sewage

and other sources may stimulate extensive growth of algae or other aquatic life. Artificial water impoundments also may promote the growth of objectionable organisms.

The complexities of disposal of wastes from the production of organic chemicals have been described by Hess and Carney (3). The residues from large diversified manufacturing processes may contain thousands of complex compounds including byproducts, process aids, unreacted raw materials, and the manufactured product itself. The volume of these wastes may be as large as that of the main product. Effective treatment methods for many of these complex materials remain to be developed. Even when practical and economical treatment has been devised, complete elimination may be impossible.

Effects on Water Supplies

The effects of the diverse mixtures of organic materials on each other, on water, and on the consumer of drinking water are only beginning to be appraised. Among those known are the production of taste and odor in water and interference with treatment of water for industrial and domestic use. Costly ion exchangers deteriorate under the attack of organic chemicals in water (4). Acids are suspected. Polynuclear hydrocarbons possessing carcinogenic

Mr. Middleton is senior scientist in charge of the Organic Contaminants Unit, Chemistry and Physics, of the Robert A. Taft Sanitary Engineering Center, Public Health Service, Cincinnati, Ohio. Dr. Rosen is organic chemist in the same unit.

These paragraphs, based on overseas reports from public health personnel with missions and field parties of the International Cooperation Administration, give a glimpse into health work abroad. The original material appears in an administrative publication distributed by the Public Health Division of the ICA.

First Movie

An Arabic language moving picture on sanitation shown for the first time in a Jordan village attracted an audience exclusively of men and boys. In Jordan villages it is not the custom for women to appear at public gatherings in male company. Rather than give up the time needed for a duplicate showing for the women, a sanitarian persuaded the villagers to separate the women and girls from the men and boys by an open aisle. This device permitted the women and girls to see their first movie; it was in fact the first movie for anyone in the village.

—ARTHUR L. DOPMEYER, acting chief, Cooperative Department for Health and Sanitation, United States Operations Mission, Jordan.

Latrines for Pilgrims

Yumbel (population 5,000), seat of the shrine of San Sebastian in Chile, receives as many as 50,000 pilgrims on the peak day of the festival and 80,000 during the week. They arrive on foot, horseback, in oxcarts, autos, trucks, special trains, and even in boxcars. For the first time in the history of the festival, health officials provided latrines for the visitors: 45 prefabricated structures placed in groups around the plaza and walled off to facilitate traffic control and cleaning several times a day. A fee of 5 pesos was charged, if user was able to

pay. Although free service was not denied, 50,000 pesos were collected. The church will pay for the installation cost (280,000 pesos) with funds collected from the pilgrims. It is planned to install 15 more latrines at other points next year. A 10,000 liter tank, a deep well, and chlorinator were installed to supplement the town's usual water supply. The visitors were impressed with the latrines and inquired about means of obtaining them for installation elsewhere.

—PHILIP L. RILEY, acting chief, Division of Health and Sanitation, United States Operations Mission, Chile.

Population Gain

For the first time in the recorded history of Orchid Island, 50 miles off the southeast coast of Taiwan, there seems to be a gain in population as a consequence of DDT spraying for malaria control. Only 1 out of 12 on the island is over 45 years old. The island has no roads, no footpaths more than 18 inches wide. There isn't a wheel to be seen. The children fish. The women grow taros. The older men watch the children. The men wear only a closely tailored fig leaf. The women seem to cover themselves where they happen to be cold.

—JAMES P. WARD, M.D., M.P.H., chief public health officer, International Cooperation Administration Mutual Security Mission to Taiwan.

Hard Going

Heavy floods, deep mud, and washed out bridges forced two physicians to abandon their jeep en route to the Okinawan Colony on the Rio Palmetillas in Bolivia. They crossed two swollen rivers and 5 kilometers of mud on foot to visit the colonists who were preparing to receive about 160 Okinawan immigrants. The colony kindly supplied horses for the return trip. At that point, the physical condition of the villagers was better than that of the doctors.

—GEORGE ADAMS, M.D., M.P.H., chief, Health and Sanitation Division, United States Operations Mission, Bolivia.

Figure 1. Bank of carbon filters used for collecting small concentrations of organic materials from water. Several thousand gallons of water are passed through these filters which adsorb organic contaminants from the water. The recovered materials are then analyzed for chemical content.

Table 2 lists the concentrations of organic materials recovered by chloroform extraction of the carbon. These materials are frequently sticky, brown semisolids having strong disagreeable odors resembling paint or varnish. Some of the samples show distinct oil layers.

It is significant that the organic materials survive standard water treatment processes and in many instances appear in the finished water in concentrations equal to those found in the raw water.

Little information is gained from the com-

characteristics were detected by Wedgewood (5, 6) in waste effluents of domestic and industrial origin. An extensive review of the literature on the toxicity of materials known to be discharged into water has been initiated (7).

Taste and odor in drinking water, the most obvious contaminating effect of organic chemicals, is a widespread problem of considerable significance and causes more consumer distress than any other factor in water plant operation. In a 5-year period (1948-52) chemical costs for the control of tastes and odors at the South District Filtration Plant in Chicago (8) amounted to \$462,000, equivalent to 21.7 percent of the total chemical cost. More than 1,000 water plants in the United States use active carbon for the control of taste and odor. While carbon treatment and other methods for controlling these objectionable conditions have been developed, difficulties are frequently such that the required treatment cannot be provided.

An indirect effect on health arises when unpalatable water causes the consumer to seek other drinking water sources—even bacterially contaminated ones.

Isolation and Identification

The organic chemicals occurring in water are usually present in very low concentrations, but a few parts per billion (p.p.b.) of contaminants may produce significant taste and odor. One part per billion is equivalent to a teaspoonful of material in 1 million gallons of water.

The low concentrations, complexities, and

varieties of organic pollution in water make the recovery and identification of these substances difficult. Specific methods, with few exceptions, for the analysis of the multitude of organic chemicals in water are lacking. Furthermore, ordinary analytical techniques are usually inapplicable to the extremely low concentrations which must be studied. Some means of concentrating the materials for analysis is necessary. Methods for concentrating, isolating, and identifying these materials have been under study by the Public Health Service at the Robert A. Taft Sanitary Engineering Center. Exploiting the unique adsorptive properties of active carbon, a filter has been developed which adsorbs most organic material from water. After water or wastes in quantities from 100 to several thousand gallons pass through the filter, the carbon is dried and the organic materials are extracted with chloroform or other organic solvent in a Soxhlet extractor.

The organic substances recovered from the carbon differ with the type of solvent used for the extraction. Chloroform, the solvent used in most studies, has been found to recover those substances principally responsible for undesirable taste and odor in water. Alcohol will remove a quantity of material equal to or greater than the amount recovered by the chloroform even after preliminary extraction by chloroform. These highly water-soluble materials recovered by alcohol appear to have relatively little significance as taste and odor factors. Most materials investigated for their taste and odor effects are adsorbed quantitatively by carbon, but desorption by chloroform is only 65 to 80 percent complete. Following extraction, the solvent is removed by distillation, and the residue is subjected to further analysis. Liquid-liquid extraction methods also have been utilized for concentration of materials from some effluents.

Details of the use of the carbon filter (fig. 1) and certain applications, particularly to taste and odor studies, have been described (9, 10).

Raw and Finished Water Studies

Raw and finished waters have been sampled by means of the carbon filter in several locations and under various conditions of pollution.

Table 3. Chemical groups separated from carbon filter extracts of water samples taken from seven sources

water in an area well known for the manufacture of petrochemicals. Acrylonitrile was indicated to be a component by infrared tests. While the toxicity of these organic cyanogen compounds is not great compared to the alkali cyanides, their presence in drinking water merits further study. Alcohols, aldehydes,

ketones, acids, and esters have been found in various waters. Some of these appear to be of industrial origin while others may be naturally produced.

Insecticides

Concentrations of DDT in the range of 1 to 5 p.p.b. were found in the drinking water of sev-

Figure 2. The similarity of these infrared spectrums indicate that foam material from the raw water at Wheeling, W. Va., contained large amounts of anionic synthetic detergents.

plex residue without further chemical separation. Utilizing solubility differences, the materials are separated into the broad groups of water-solubles, acids, bases, neutrals, and phenolic materials. The distribution by groups of the chemicals recovered from various waters is shown in table 3.

The neutral materials, whether the pollutants are of industrial or natural origin, generally constitute the most abundant group. Since neutral substances are less reactive than other classes of compounds, they can be expected to resist biological and chemical attack to a greater degree. However, even hydrocarbons that are quite stable chemically may be attacked biologically. Neutral compounds which may occur in water are aliphatic and aromatic hydrocarbons and their halogen derivatives, alcohols, aldehydes, ketones, ethers, esters, nitro compounds, amides, nitriles, sulfides, and many others. The neutral substances are frequently sources of intense odor which can be detected when only a few parts per billion are present.

Hydrocarbons and Related Materials

Aliphatic and aromatic hydrocarbons have been consistently isolated from drinking waters obtained from sources in the vicinity of petroleum refinery waste outfalls. These materials survive water treatment processes in concentrations sufficient to cause serious impacts on taste and odor. Associated with these materials are sulfur compounds, probably cyclic sulfides, also responsible for odor in water. A study of taste and odor components in refinery effluents and a method for identifying petroleum wastes in surface waters have been published (11, 12).

As much as 1 p.p.m. of organic material was recovered in the drinking water of a city located 10 miles below an area containing a concentration of chemical industries. Materials found include substituted benzene compounds, kerosene, polycyclic hydrocarbons, and phenyl ether. Intense odor was a pronounced characteristic of the recovered materials. The phenyl ether recovered was detectable by odor tests at a concentration of 5 p.p.b.; the pure laboratory reagent at 13 p.p.b.

Phenolic compounds have long been recog-

nized as being detrimental to water quality, particularly from the standpoint of taste and odor. These compounds are associated with waste products from coke plants, oil refineries, and other industries. The taste and odor intensity of many phenolic substances is increased several hundredfold when reacted with the low concentrations of chlorine ordinarily used at the water treatment plant. A 1 p.p.b. concentration of the chlorinated materials may be detectable by taste and odor. However, phenolic pollution is more amenable to control at the water plant than other types of pollution.

Petrochemical wastes have presented problems recently. No standard definition of the term "petrochemical" is available but the book "Petroleum Processing" suggests:

PETROCHEMICAL, *n.*: A chemical compound or element recovered from petroleum or natural gas or derived in whole or part from petroleum or natural gas hydrocarbons, and intended for chemical markets.

Included in this group are such familiar chemicals as alcohols, benzene, ammonia, carbon black, acetone, aniline, styrene, and sulfur. Wastes from the manufacture of these materials are complex and highly odorous. Where wastes are discarded into streams without adequate treatment, outbreaks of intense taste and odor have occurred. On one occasion, under winter conditions, the taste and odor were reported to have traveled 1,000 miles. The waste materials responsible were recovered from drinking water 400 miles from the point of discharge and were partially identified.

The development of the petrochemical industry has come about almost entirely since 1940. It is estimated that, at present, there are over 300 petrochemical plants (13) in operation in this country. In 1954, this industry produced 27 billion pounds of petrochemicals comprising approximately 25 percent of the total chemical production.

The rate of expansion of petrochemical production indicates that in 1965 this industry will be the source of half the chemicals produced in the United States. The extensive uses of petrochemicals derived from crude oil and natural gas cracking are summarized in the inset (p. 1130).

Nitriles have been isolated from drinking

Figure 3. Picture of frothing conditions of sewage plant at Benton Harbor, Mich. The exact causes of this foaming condition are not known but synthetic detergents have been implicated. Analysis has shown large quantities of detergents in the foam.

such materials as DDT in water may not be significant from the standpoint of human physiological effects, concentrations below 1 p.p.m. of chlorinated insecticides are toxic to fish (16); toxaphene (17) has been reported to be lethal to fish in 10 days at less than 6 p.p.b. concentration.

Synthetic Detergents

Synthetic detergents as potential water polluting materials are receiving much more attention since the occurrence of excessive foaming at water plants in Kansas and West Virginia (18, 19). These materials are unique in that virtually all of the product ends up as waste. A review of the detergent problem has been published (20). Foam materials from Wheeling, W. Va., were identified by means of infrared spectrums as originating from synthetic detergents of the alkylarylsulfonate type (anionic). (Approximately 80 percent of all detergent produced is of this type.) The striking resemblance of the infrared spectrums of the pure material and materials recovered from the foam (fig. 2) leaves no doubt as to the presence of surfactant in the foam. Tastes, odors, and interference with water treatment

have been ascribed to the presence of these materials in concentrations of a few parts per million. This concentration does not normally occur in water. These substances are resistant to biological forces of purification in the stream and will survive usual water treatment processes although they are readily adsorbed by active carbon. Small concentrations have been isolated from tap water, and the materials undoubtedly constitute a portion of our daily organic intake with drinking water.

Sewage treatment plants have experienced troublesome foam problems. Foaming may be due to causes other than detergents, but in a number of instances high concentrations of anionic materials have been present in the foam materials. Samples of the foam from the Benton Harbor, Mich., plant (fig. 3) were shown by infrared methods to be high in detergent materials. A report (21) has described the difficulties of the frothing at this plant.

Natural Materials

Products of natural origin in water are frequently responsible for taste and odor difficulties. In addition, kills of wild and domestic

eral cities using rivers as sources of supply. The insecticide could not be recovered at all times but persisted for a 6-month period in one location. The major source of the DDT was presumed to be spray operations.

Through the widespread agricultural use of

DDT, exposure resulting from various sources (14, 15), particularly food, is much higher than the exposure that could result from ingesting drinking water containing a 5 p.p.b. concentration, the estimated maximum level found in the waters examined. Although present levels of

technical publications

The Dentist in the U. S. Public Health Service

PHS Publication No. 475. 20 pages; illustrated. 15 cents.

Opportunities for dental officers in the commissioned corps of the Public Health Service are shown in this booklet. It outlines the admission requirements for the Regular and Reserve Corps and describes the integration of dental research, clinical dental practice, and dental public health within the Service.

Basic, clinical, and applied research are conducted, respectively, at the National Institute of Dental Research, the Clinical Center of the National Institutes of Health, and the Division of Dental Resources.

Dentists are assigned to treat merchant seamen, Coast Guardsmen, Indians, and other eligible groups at Service hospitals and outpatient clinics.

Preventive measures which can be widely applied are the responsibility of the Division of Dental Public Health. Here dental officers develop

or improve methods of preventing or controlling dental diseases. They may also be assigned to provide consultation and assistance to States and communities endeavoring to improve dental health.

Clinical Memoranda on Economic Poisons

PHS publication (unnumbered). 1956. 78 pages. Multilithed.

The Technical Development Laboratories of the Communicable Disease Center has issued its annual revision of the material on economic poisons (see *Public Health Reports*, September 1955, p. 836).

The book is divided into five sections: organic phosphorus insecticides, chlorinated hydrocarbon insecticides, solvents, rodenticides, and miscellaneous compounds.

Each section gives general information applicable to the group of compounds under consideration, and

each memorandum gives information on the identity, formulations, and uses of a poison. Toxicology of the poison with specific reference to human cases, its dangerous dose to man, laboratory findings, and treatment are discussed.

Appendixes A-E give instructions for collecting and shipping of samples for the analysis of pesticides or determination of their physiological effects.

Copies are available from the Communicable Disease Center, Public Health Service, Atlanta, Ga.

This section carries announcements of all new Public Health Service publications and of selected new publications on health topics prepared by other Federal Government agencies.

Publications for which prices are quoted are for sale by the Superintendent of Documents, U. S. Government Printing Office, Washington 25, D. C. Orders should be accompanied by cash, check, or money order and should fully identify the publication. Public Health Service publications which do not carry price quotations, as well as single sample copies of those for which prices are shown, can be obtained without charge from the Public Inquiries Branch, Public Health Service, Washington 25, D. C.

The Public Health Service does not supply publications issued by other agencies.

animals have been associated with blooms of certain toxic algae. Odors of these materials are often described as musty, earthy, pigpen, geranium, fishy, and cucumber. Many of these odors have been associated with algae. Silvey (22, 23) has proposed that actinomycetes are responsible for musty and other odors in various waters, particularly in the southwest. The chemicals elaborated by the organisms have not been identified. A musty component has been recovered from numerous waters in the Cincinnati laboratory by extended purification following steam distillation of the neutral materials. This material constitutes a very small percentage of the total extract but possesses an extremely intense odor.

Waters from various surface sources have contained substantial quantities of carbonyl compounds. Such materials as organic acids, ketones, and aldehydes may result from natural decay, oxidation, and life and death processes of plants and other aquatic life. Organic acids may also represent an intermediate step in the oxidation of industrial materials, including hydrocarbons. Hence identification of these materials does not reveal their origin.

Much remains to be learned of all the effects natural products have on the pollution of our water resources. One objective of studies in progress at the Robert A. Taft Sanitary Engineering Center is the determination of the role of algae as sources of taste and odor. Further chemical studies are being pursued in areas experiencing difficulties in taste and odor where nonindustrially polluted waters serve as a source of supply.

Summary

Water quality is seriously affected by contamination from organic materials. Both drinking water and industrial supplies are impaired. Apart from the nuisance and deprivation caused by effects on drinking water, it is conceivable that physiological effects may result from high concentrations of these materials in public water supplies. At what concentration materials such as those isolated from drinking water constitute a hazard is not known. Many of the organic materials in water have not yet been isolated or identified.

Methods for studying these materials have been indicated and some of the results outlined. In view of the increased industrialization, increased water use, and the present lack of knowledge of natural pollutants, the total effects of organic chemicals on water quality and means for the control of the materials demand increased attention.

million men with a history of tobacco use, 31 million had smoked cigarettes regularly at some time during their lives. The corresponding numbers of lifetime male cigar and pipe smokers were 4.8 and 7.9 million, respectively. The numbers of current regular male smokers were as follows: cigarettes, 26 million; cigars, 2.8 million; pipes, 3.9 million. Of the 18 million women who reported some use of tobacco, 15 million had at one time or another been regular cigarette smokers. Thirteen million were regular smokers at the time of the survey. All of these estimates have been adjusted to take account of persons in the sample for whom no smoking histories were obtained.

Cigarettes are the major form of tobacco used. Trade sources estimate the number of cigarette smokers at about 60 million, and this figure probably includes "discontinued" smokers. If one adjusts the survey results to include occasional smokers, persons in military service and in institutions, and smokers presently under 18 years of age, the maximum resulting estimate of cigarette users to be derived from the survey is about 55 million. Some of this discrepancy between the survey estimate and that of trade sources may be traced to different estimates of the proportion of women smokers.

The profiles of age and sex differentials in tobacco use resulting from comparisons based on current practices or lifetime history of use are very similar, particularly for cigarettes. The highest percentage of current regular cigarette smokers appears at 25-34 years of age among both males and females and tapers off in successively older groups. The sex differentials in the proportion of smokers (or nonsmokers) is greatest at ages over 65. Among men over 65 years of age, pipe smoking rivals cigarette smoking in popularity. The differential in favor of cigarettes widens at the younger ages. Moreover, in the younger cohorts there seems to be a shift to "pure" cigarette smoking, accompanied by a lessened tendency to take up cigars or pipe exclusively.

A shift to an earlier age for starting to smoke is observed for younger persons. This has accompanied the rising proportion of regular smokers in these younger age groups. The smoking habit characteristics of a cohort become evident by a rather early age, around

age 18 to 20 for men and at a slightly older age for women. Much of the decline in the number of cigar and pipe smokers may be traced to a failure of these forms of smoking to attract converts at an early age among persons born since 1900.

Aside from differences associated with age and sex, urban-rural residence is the population characteristic which differentiates smoking habits most sharply. Rural nonfarm persons closely resemble urban dwellers in smoking habits, and the sharp demarcation appears between the rural nonfarm and rural farm populations. The farm and nonfarm populations acquire the smoking habit at virtually the same age as the urban population. Among men, the urban-rural differences are emphasized when comparison is restricted to cigarette smokers using more than one pack of cigarettes daily. Cigarette smoking has been increasingly accepted by urban women born after 1890. Sizable acceptance among farm women was delayed almost one generation, to women born after 1920.

Practically no differences in smoking patterns according to size of urban community were noted. This finding is at variance with earlier surveys and suggests that the events of the past 20 years have disposed of community size as an important determinant in shaping smoking habits.

For men, there is little variation in the distribution of smoking patterns in the four major regions of the country (Northeast, North Central, South, and West). The proportion of female nonsmokers is lower in the northeastern and western regions than elsewhere. A higher proportion of heavy cigarette smokers was noted among northeastern males and the excess cannot be accounted for solely by greater urbanization of that area.

The differences between whites and nonwhites with respect to the proportions of nonsmokers and of all regular cigarette smokers are trivial. However, the proportion of white male cigarette smokers who use more than one pack of cigarettes daily is almost double the proportion among the nonwhite males. A similar excess occurs among white females. Urban-rural gradients provide another distinction. Among white males, the rural nonfarm data on tobacco use resemble those for the urban population.

A Survey of Tobacco Smoking Patterns in the United States

As a supplement to the United States Bureau of the Census Current Population Survey for February 1955, smoking histories were collected from approximately 40,000 men and women 18 years of age and over. Persons in the survey were a representative cross section of the population of the United States. The questionnaire regarding smoking history was similar to that used by the American Cancer Society and the National Cancer Institute in their forward studies on the association of smoking and lung cancer. The questions covered the use of cigarettes, cigars, and pipe tobacco, attempted to distinguish between occasional and regular smokers, and included items on age at which smoking was started and the maximum consumption rate ever attained. The census information on age, sex, residence, race, and other population characteristics was made available for analysis.

The survey objective was to classify the population by broad smoking categories, and no attempt was made to validate verbal statements on rate of use by diaries or other records of consumption or purchases. Current cigarette consumption as estimated from the survey data was checked against the national aggregate consumption determined from tax data, which indicated that the survey underestimated cigarette consumption by approximately 15 percent. Considering the different intent for which the questions on smoking were designed, the correspondence between the survey and tax estimate seems good.

Of the 49.6 million men and 55.1 million women 18 years of age and over in the civilian population outside institutions, 11 million men (23 percent) and 37 million women (67 per-

cent) are reported to be nonsmokers, that is, they had never smoked tobacco occasionally or regularly in any form. Of the remaining 38

Public Health

MONOGRAPH

No. 45

The accompanying summary covers the principal findings presented in Public Health Monograph No. 45, published concurrently with this issue of Public Health Reports. Mr. Haenszel and Dr. Shimkin are with the National Cancer Institute, National Institutes of Health, Public Health Service, Bethesda, Md., and Mr. Miller is with the U. S. Bureau of the Census.

Readers wishing the data in full may purchase copies of the monograph from the Superintendent of Documents, Government Printing Office, Washington 25, D. C. A limited number of free copies are available to official agencies and others directly concerned on specific request to the Public Inquiries Branch of the Public Health Service. Copies will be found also in the libraries of professional schools and of the major universities and in selected public libraries.

Haenszel, William, Shimkin, Michael B., and Miller, Herman P.: Tobacco smoking patterns in the United States. Public Health Monograph No. 45 (Public Health Service Publication No. 463). 111 pages. Illustrated. U. S. Government Printing Office, Washington, D. C., 1956.

The Nationwide Fight Against Blindness

By FRANKLIN M. FOOTE, M.D., Dr.P.H.

TO ATTEMPT to envisage the estimate of 334,000 blind persons in the United States, imagine a city as big as Miami, Fla., or Omaha, Nebr.—a city in which every man, woman, and child is blind. It is further estimated that more than 27,000 persons lose their sight each year and that, unless our preventive efforts can be made more effective, three-fourths of a million persons now living will become blind before they die. The cost of caring for the blind—education, braille and talking books, seeing-eye dogs, lighthouses, pensions, and other of the inadequate services we try to provide—amounts, according to the American Foundation for the Blind, to \$150 million each year.

Fortunately, there has been considerable progress in preventing blindness. Infectious causes of blindness show a great drop. When the National Society for the Prevention of Blindness was established in 1908 by Miss Louisa Lee Schuyler and Dr. F. Park Lewis, almost one-third of the children in schools

for the blind were there because of ophthalmia of the newborn. The crusading spirit that brought about legislation in every State requiring the use of prophylactic drops in the eyes of every newborn child, coupled with antibiotic treatment of those rare cases which now occur, has brought this cause of blindness to the vanishing point. Health education plus sulfa treatment have almost wiped out trachoma in this country. Although smallpox is responsible for 10 to 20 percent of blindness in some countries which have not had the benefits of the advancing medical sciences, it is virtually unknown here. In only 20 years there has been a reduction of 60 percent in syphilis as a cause of blindness among children in schools for the blind because many States have enacted wise legislation requiring blood tests before marriage and early in pregnancy. Health education and effective treatment of infected patients also have reduced the effects of syphilis.

Even eye injuries as a cause of blindness among children in schools for the blind show a significant decrease: 40 percent in the past 20 years. This decline can perhaps be attributed in part to sound legislation such as that controlling sale of the more dangerous kinds of fireworks and controlling use of air guns, in part to health education of young parents by public health nurses and social workers, and in part to improved methods of therapy.

Retrolental fibroplasia as a cause of blindness has come to play an all too prominent role. It is estimated that there now are 8,000 children blind from this one cause. For years, the National Society for the Prevention of Blindness has been interested in promoting research on this problem. The organization established

Dr. Foote is executive director of the National Society for the Prevention of Blindness. A graduate of Yale University, where he obtained his degrees in medicine and public health, he began his public health career in 1935 in Tennessee as a county health officer. He served as chief of the local health administration division of the Connecticut State Department of Health and also as a district health officer in New York City, before serving in the Medical Corps of the United States Army during World War II. At the present time he is president of the New York State Academy of Preventive Medicine.

Among nonwhites, the reverse is true, the nonfarm data resembling those for the farm population.

Smoking is less prevalent among farmers than among other male occupational groups. Among nonfarm workers, professional and technical personnel had the highest proportion of nonsmokers. There is evidence of some ordering by social class, the white-collar groups having more nonsmokers than craftsmen or operatives. This ordering by social class, noticeable for nonsmokers and for all regular cigarette smokers, tends to disappear when comparison is limited to smoking more than one pack of cigarettes daily.

The survey data support the observation that military life encourages the adoption of the smoking habit. The greater use of tobacco among soldiers persists after they leave military service.

The results by marital status point to a small deficit of smokers among single persons of both sexes. The proportion of nonsmokers among divorced persons of each sex is lower than for the remainder of the population.

Proportionately more men than women were reported as discontinued smokers at the time of the survey. When sex differences in the number of smokers and length of exposure to the habit are taken into account, the difference

between men and women with respect to discontinuance disappears. For cigarettes particularly, discontinuance rates fall into consistent age patterns and show some stability over a variety of population groups, although in examining the data by population subgroups, a rather general inverse relationship between the proportion of regular smokers and the discontinuance rate does appear. It does not appear necessary to qualify group comparisons, based either on maximum or current rate of smoking, by taking into account the effect of discontinuance on duration of exposure to the habit.

The major purpose in collecting smoking histories was to investigate the meaning of the reported associations between smoking and lung cancer and to check whether the distribution of lung cancer deaths is consistent with estimates of the excess risk among smokers and the distribution of smokers in the population. The application of the data to test proposed models for lung cancer etiology was reported in the *Journal of the National Cancer Institute*, June 1956. This report is devoted solely to presentation of the census findings, and it is hoped that these data may prove useful to persons interested in the social, economic, and marketing aspects of tobacco use, as well as to investigators interested in lung cancer.

Correction

In table 2, page 654, July 1956 (Effect of Fluoridated Public Water Supplies on Dental Caries Prevalence, by F. A. Arnold, H. T. Dean, P. Jay, and J. W. Knutson), the def rate for 7-year-olds in 1950 should read 4.72, and the def rate for 11-year-olds in 1953 should read 1.09, both in Grand Rapids, Mich.; in table 3, page 655, the DMF rate for 6-year-olds in Grand Rapids in 1953 should read 0.19.

react as did 69 percent of the eye patients in a recent study made by a California oculist (1). Since they never before had heard of the disease, how could they understand its implications? Many persons may believe that eyedrops advertised in a bus, new eyeglasses, or even proper illumination are all that is needed to treat or avert what you and I know to be serious conditions.

Need for Continuous Education

In 1951, Owens, Cox, and Hochreiter (2) reported on 100 blind persons in the Baltimore area in an attempt to determine why they had lost their sight. For approximately half the patients, they found that either there was no effective care or treatment available or, if available, that everything possible had been done at the right time, without avail.

For the other half, it was felt that blindness could have been prevented but was not for various reasons. For 31 out of 50, the reason was attributed to the patient: lack of knowledge of early symptoms of eye disease and the importance of seeking and carrying out competent ophthalmological advice. In some cases where the patient sought advice from the family doctor or some other practitioner, referral to an ophthalmologist was not made for many months or even years. A few of the preventable cases of blindness were from accidents.

Medical societies and departments of public health are doing much to inform the public on health matters in general, but their efforts in so specialized a field as blindness prevention need reinforcement. Therefore, a voluntary citizens' agency, such as the national society, in which both professional and informed lay persons are joined in partnership, can make a significant contribution in bringing about a more informed public. If he is one of those who has been informed, an eye patient will be more likely to cooperate in the plan of treatment outlined when told of the diagnosis and the regimen to be followed.

The Mass Media

Our public education program has become more effective since we have given it full-time

attention. The month of September 1955 was again proclaimed "Sight Saving Month" by 30 State governors and by many mayors. Because the national Advertising Council approved this intensive campaign, it is estimated that more than a million dollars' worth of radio and television time was devoted to messages about care of the eyes. Science reporters and magazine writers in increasing numbers are coming to our headquarters for suggestions and to verify their data. During the past 3 years several magazines which reach millions of persons have carried well-written and scientifically sound articles on eye problems, whereas less than 20 years ago no such story had ever appeared in the mass media. Although misleading articles and those apparently designed for self-promotion are published occasionally, the careful checking being done by many magazines and newspapers indicates vast improvement in the reliability of the material they use.

Aside from the mass media of communication, the national society works with all professional groups that are or should be interested in sight conservation. For instance, some of our information efforts are directed toward keeping the general medical practitioner and the pediatrician up to date on advances in ophthalmology.

Local Programs

One of our departments works with teachers colleges and State and local departments of education to keep the million school teachers of our country alert to eye health problems. To improve vision screening programs for school and preschool children, the national society has helped to support important research on vision testing, and our nurse consultant works with public health nurses and volunteer groups.

The value of medical social service activities has been clearly demonstrated in such centers as the eye and ear infirmaries of Massachusetts and of Illinois. Our staff medical social work consultant seeks to improve the provision of followup for eye clinic patients and those needy persons being served in State and local welfare programs.

Because we have not yet arrived at that millennium when all persons have chosen an eye

a committee in 1951 which finally led to a coordinated attack on blindness, participated in by 18 hospitals and 75 investigators and sponsored by the Public Health Service's Institute of Neurological Diseases and Blindness, the National Foundation for Eye Research, and other agencies as well as the society.

Although the entire story of the mechanism of how oxygen leads to retrolental fibroplasia and how oxygen can be given when necessary without producing blindness has yet to be elucidated, steps already taken to avoid excessive administration of oxygen to premature infants have virtually eliminated this cause of blindness from many hospitals. In the State of New York, 18 newborn infants were reported to the Commission for the Blind in 1954 as being blind from this disease in that year. In 1955 this figure had dropped to 3. The national society has contributed more than \$40,000 in grants-in-aid for research in retrolental fibroplasia.

The discussion thus far—ophthalmia of the newborn, syphilis, injuries, and retrolental fibroplasia—has provided examples of primary prevention, action to prevent blindness even before the cause begins to operate.

Impact of the Later Years

Despite the progress that has been made, there is reason to believe that the actual number of the blind in the United States is increasing. This increase is in part produced by our increases in population. In part it also reflects the advances made in the past 50 years which have added 20 years to the average span of life—from 48 in 1900 to 69.6 at present. Today, many more persons live to an age when glaucoma, cataracts, and other eye diseases are more frequent and when such diseases as diabetes and arteriosclerosis produce loss of sight.

The chronic eye diseases of middle and later life constitute a much greater problem than those discussed earlier. Many of them cannot be cured in the light of our present knowledge, and the best we can hope to do for some of these conditions, such as glaucoma, is to retard them. This kind of prevention of disability is coming to be known as secondary prevention: The disease is clearly present, but something can be done through early detection and

optimum treatment to prevent or at least to lessen the extent of disability. In some instances, such as cataracts, retinal detachment, and corneal disease, surgery often restores sight if performed at the proper time.

Much of the prevention of blindness in the past has been accomplished by influencing relatively small numbers of people. For example, boards of education can require vaccination against smallpox before a child enters school; then their staffs will see to it that every child is vaccinated. Boards of health or State legislatures can require the use of prophylactic drops in babies' eyes immediately after birth, and proper enforcement procedures will make sure that this is done. Hospitals can require adequate control of oxygen if it is prescribed for a premature infant, and we should have little or no more retrolental fibroplasia.

But there seems to be no easy procedure that we can direct people to follow to prevent blindness from most of the eye conditions of middle and later life. The patient with a detached retina needs early and competent care if the required surgery is to be successful. The patient with acute uveitis, with glaucoma, with many other conditions, needs early care and needs to follow the oculist's instructions to the letter if he hopes to avoid loss of sight. The patient with a detached retina must get into the proper hands, accept the diagnosis, and be willing to have an operation promptly.

This means that we are discussing individual, highly personal problems. It means that we must somehow influence in the right way every one of the 167,000,000 persons in the United States if we are to make progress in combating blindness from these causes.

The average person, in my opinion, does not like to go to a doctor, even when he has serious eye symptoms. Even though he is frightened by the idea of blindness, he has a good deal of inertia and hopes that somehow his eye trouble will go away by itself, the way it came. He did not ask for his symptoms and cannot understand why he should be bothered by them. I think he would far rather buy a new television set than pay for an eye examination, and if, by some chance, the eye examination reveals nothing wrong, he feels cheated. If a serious eye disease such as glaucoma is diagnosed, he may

hances or adds pleasure to life. In view of what America is willing to spend on products of such ephemeral value, though, this Nation will certainly appreciate the greater and more lasting value of research and prevention. If we can stimulate such research and apply present and future knowledge to the prevention of blindness, our progress will exceed even the impressive advances already achieved.

Air Pollution Demonstration Projects

A grants-in-aid program for demonstration projects related to air pollution and its control has been established by the Public Health Service. These projects are for the purpose of evaluating or demonstrating the effectiveness of various methods of preventing and combating various air pollution problems.

State and local government air pollution control agencies and other public agencies may apply for grants-in-aid for air pollution demonstration projects at any time.

Applications will be reviewed on the basis of the relative need for such a project; the adequacy of facilities and skills available; the characteristics of the air pollution problem in the area; how the results will apply to other parts of the country; and how much the applicant can contribute to the total cost of the project.

Grants for demonstration projects will be for a specific amount paid in a lump-sum to the grantee for 1 year. They may be renewed for two additional periods of 1 year each, depending on the availability of Federal aid. Demonstration project activities must begin within 6 months after the grant is approved and must be used only for the specific project.

Information about these grants may be obtained from any of the Regional Offices of the Public Health Service or from the Chief, Division of General Health Services, Bureau of State Services, Public Health Service, Washington 25, D. C.

doctor and go to him periodically for an eye checkup, it seems well to encourage experimentation with screening programs for adults as well as for children. Among adults, it is evident that a screening test for visual acuity, ophthalmoscopic examination, taking the tension with a tonometer, and possibly using the Harrington multiple-pattern test of field of vision will discover about one person in 50 over the age of 40 years with glaucoma (3-5). Where such surveys have been conducted, at least one result has been that everyone concerned has learned what glaucoma is and what value there is in early diagnosis and continued treatments.

In vision screening activities, participated in by the national society in various States, an important byproduct has been the education of volunteers assisting in the programs. In the course of their training, hundreds of volunteers have become informed about such eye topics as the need for early care of children with strabismus. They have learned that there is no such thing as a "minor" symptom of eye trouble and that what might appear to be a relatively trivial symptom, such as slight blurring of vision or difficulty in reading the newspaper, may be the only early warning sign one will have of so dangerous an eye disease as glaucoma. Nearly all these volunteers are women, and their new-found knowledge finds its way to club meetings, coffee parties, and bridge games. A well-trained volunteer may help to pass on information to 5 or 10 other adults.

Safety Glasses in Industry

It is estimated that 300,000 eye accidents still occur each year in industry, in vocational shops, and at home. Our objective in industry is to promote not only eye safety but also improved screening programs which will help to reveal otherwise unrecognized eye disease. Eye safety is being aided by an incentive program known as the Wise Owl Club, which originated in St. Louis in 1947. Admission to this exclusive club is won by a worker if his eyesight has been saved by the conscientious wearing of safety glasses at the time a work accident occurs.

The occasion of an award dramatizes the fact that a man's vision has been saved, a fact that

otherwise might pass unnoticed. We now have records on nearly 10,000 Wise Owl members who have had the sight of at least one eye saved by wearing safety glasses. More than one-fourth of this group saved the sight of both eyes. This is an impressive number of men and women who would be blind but for the preventive measures that have been accepted.

Need for Research

The Baltimore study by Owens showed that about half of the blindness now occurring could not have been prevented no matter what was done. The need for both fundamental and clinical research in the blinding eye diseases is therefore obvious. The support that the national society has given to some projects in this field has already been indicated. We have also tried to stimulate the interest of various foundations in the field of eye research, and at various times have presented information on the need for ophthalmic research to congressional committees. In the early days of the national society, it had become apparent that there was need for data on the extent of blindness, on the relative importance of various causes, and on their incidence by sex, age groupings, race, and geographic factors. When the material produced by our statistical division (6) was presented to a congressional committee in a fact sheet in June 1949, Committee Chairman Percy Priest called it "very helpful."

It has already been noted that blindness is costing us at least \$150 million each year. In contrast, the American people are allocating not more than \$3 million, or possibly 2 percent of this amount, to eye research and to organized programs for prevention. One might ask whether we can afford to put more into prevention and into research. The answer lies in our sense of values, indicated by retail sales of nonprescribed eye lotions and eye washes in the amount of \$4,910,000, and mascara, eyebrow pencil, and eye shadow to the sum of \$7,180,000 (7). And, of course, billions more are spent on commodities and services which are far less valuable than the protection of human eyesight.

In quoting these figures I do not wish to imply that anyone should be deprived of what en-

advised to douche and refrain from sexual intercourse for at least a week. They were asked to return in 1 week and again in 4 weeks when re-examination and repeat smears were taken. Any patients whose smears were positive were re-treated with the same schedule as before.

Results

On pretreatment examination, 122 of the original 150 women in the study were found to have a smear positive for gram negative intracellular diplococci from either cervix or urethra, or both. Of these 122 women, 85 (70 percent) were treated. They returned to the clinic as directed for two followup examinations. Smears taken at these examinations were negative for the diplococcus. Thirty-four women failed to return, while three who completed the followup were found to be positive for the diplococcus. Of the original 150 women in the study, 28 had negative smears on initial examination and smears continued to be negative throughout the 30 days during which they were under observation. Of the original 150 women, 10 were renamed as contacts to men suffering with gonorrhea during the study period, and examination of these women showed 4 to be positive and 6 negative for gonorrhea.

In a study undertaken February through June 1955, it was ascertained that 15 percent of all female contacts were renamed by men with a diagnosis of gonorrhea during a period of 60 days following initial identification of the women as contacts. A similar study conducted February through March 1956, after the introduction of benzathine penicillin G for the treatment of gonorrhea in women, showed that 6.7 percent of contacts named (10 in 150) were renamed. This is a significant reduction, and we feel it is due entirely to the change in therapy.

There has also been a reduction in the number of men entering the clinic and diagnosed as having gonorrhea during the period January 1-May 25, 1956. The accompanying table shows this reduction to be the first of any magnitude since accurate records were kept, beginning March 16, 1953. It is true that this reduction has occurred only for a very short period but we have reason to believe, because

of the downward incidence of gonorrhea week by week until the day of the writing of this paper, that it will continue.

Gonorrheal infections in males treated in Memphis and Shelby County Health Department, January 1954-May 1956

¹ Beginning January 1, 1956, female contacts were treated with 600,000 units PAM and 1.2 million units Bicillin.

² Beginning April 1, 1956, males were treated with 600,000 units PAM and 1.2 million units Bicillin.

The addition of long-acting penicillin in the treatment of gonorrhea seems to have started a reduction in incidence of the disease in the venereal disease clinic of the Memphis and Shelby County Health Department. It is believed, however, that without the "speed zone" epidemiology technique a change in therapy alone would be ineffective. It is equally obvious that this technique alone over a 3-year period has in itself been equally ineffective. A combination of the two is necessary for success in the reduction of the incidence of gonorrheal infection in the community.

Conclusions

Speed zone epidemiology in itself is not adequate to control gonorrhea.

The addition of a long-acting antibiotic reduces the number of women reinfected and renamed as contacts within 60 days.

The addition of a long-acting antibiotic as a therapeutic agent reduces the incidence of gonorrhea in men.

Speed Zone Epidemiology: A Preliminary Report On Benzathine Penicillin G For Gonorrhea in Women

By CARL E. HOOKINGS, M.D., D.P.H.,
and L. M. GRAVES, M.D.

SINCE the discovery by Neisser of the role of the gonococcus in gonorrheal infections, efforts have been made to prevent the spread of this organism from one person to another. With the advent of penicillin in 1944, it was hoped that gonorrhea would be rapidly controlled, but this hope has not been realized. Since there has never been any difficulty in effecting cures in men no matter what type of penicillin has been used, one is led to believe that the reason for continued high rates is that infection in women is either undetected, inadequately treated, or both.

The Venereal Disease Control Clinic in the Memphis and Shelby County Health Department on March 16, 1953, set up a "speed zone" epidemiology program. In speed zone epidemiology all male patients are interviewed for the names of contacts and an effort is made to bring these contacts to examination and treatment within 72 hours.

The results of this program have been disappointing. Between March 16, 1953, and March 16, 1956, 9,835 men were admitted to the clinic. They named as contacts 15,410 women, of whom 12,921 were within the jurisdiction of the health department. Of these 12,921 women, 83.5 per cent have been brought to examination and

treated either as infected patients or as possibly incubating contacts. In the first year of the "speed zone" epidemiology program, 3,229 men with gonorrhea reported to the clinic; in the second year, 3,397; in the third year, 3,209. The contact index remained at the 1.5 level over the 3 years. We have felt that our failure to reduce the incidence of gonorrhea has been due to our inability to control the disease in women.

Should a woman have sexual intercourse with a man within 24 hours following her treatment, it is conceivable that he may contract gonorrhea and, though he name her as the contact, she may be found to be free of the disease. Such an infection has nothing to do with the adequacy of therapy; at the time of contact the penicillin had not yet killed the gonococci. Apparently the sex activity of certain patients is such that the therapeutic agent does not have the opportunity to act long enough to prevent the woman from contracting the infection herself or from giving the residual infection to her partner.

The present study was undertaken to determine whether therapy has been adequate and whether other therapy might be more effective. Therapy had consisted of 600,000 units of procaine penicillin with aluminum monostearate (PAM) to each female patient plus the advice to take vinegar douches and to refrain from sexual intercourse and indulgence in alcohol for at least a week. Abstinence from alcohol was intended to increase resistance to infection and to sexual impulses. We decided to determine whether the addition of 1.2 million units of benzathine penicillin G (Bicillin) with a consequent longer lasting blood level of penicillin would improve the female patient's chance of bacteriological cure and reduce the incidence of repeat visits by female contacts. (Benzathine penicillin G was supplied by Wyeth Laboratories under the trade name Bicillin.)

During this study, 150 women, named as contacts, were admitted to the Memphis and Shelby County Health Department Clinic and cervical and urethral smears were taken. All of these women were given 600,000 units of PAM and 1.2 million units of benzathine penicillin G and

Dr. Hookings is director of venereal disease control, and Dr. Graves is director, Memphis and Shelby County Health Department, Memphis, Tenn.

on prescription on a large scale in England and Wales as was revealed by two analyses. Dunlop and associates examined 17,301 prescriptions covering the month of September 1949 and found that 1,636 or 9.4 percent were for barbiturates. In an analysis made by the Ministry of Health of 106,295 prescriptions issued during October 1954, 8.8 percent were for barbiturates or preparations containing barbiturates. The percentage of all prescriptions in which barbiturates were the sole or principal agent in 1954 was 6.4 percent. It is apparent that these highly useful drugs are widely used.

Misuse of Barbiturates

In any consideration of misuse it is necessary at the outset to examine assertions concerning their allegedly promiscuous use. Parenthetically, it should be stated that consideration of promiscuous use at this point is restricted to usage of barbiturates at their usual hypnotic or sedative level; usage of them in excessive doses will be considered separately. By promiscuous use is meant their unrestricted, indiscriminate use when they are unnecessary, ill-advised, or contraindicated. It carries the connotation of misuse.

The allegation concerning barbiturates is twofold. It has been charged that the public is obtaining barbiturates illegally and taking them without advice of a physician; and that some physicians are prescribing barbiturates irresponsibly. The argument is based in part upon the increasing annual production of barbiturates and the calculated per capita consumption of them. Taken alone this is scarcely a reliable argument. For an increase in consumption is not necessarily *prima facie* evidence of misuse. It has already been noted that pharmaceutical manufacturers increasingly have incorporated small sedative doses of barbiturates in mixed preparations.

As for the allegation against physicians, it is the opinion of Fazekas and Koppanyi that the great volume and proportion of legally prescribed barbiturate preparations are mainly responsible for the widespread belief

that barbiturates are used promiscuously in therapeutics. From their study on whether barbiturates were being promiscuously prescribed, they concluded that physicians were using barbiturates for disturbed states because there was no specific or an equally good therapeutic product available. In the opinion of these investigators, the physicians were using the barbiturates rationally and with full knowledge of the limitations; and they were waiting only for the advancement of medical science to provide an effective therapeutic alternative or preferably replacement. Fazekas and Koppanyi predicted that if physicians had "at their disposal truly etiotropic drugs for anxiety and tension states, they would certainly not prescribe barbiturates."

The wide prevalence of psychiatric complaints among the population must add up to a large volume of legitimate therapeutic need. In applying the proper rationale to meet this need physicians have little latitude of choice. Prescriptions of barbiturates to meet this need would not per se be promiscuous. Rather, it would be a discharge of inescapable responsibility with the most effective therapy available.

Categories of Misuse

Like many things of value, barbiturates are undoubtedly misused. When there is use in excessive amounts and overdosage or in conjunction with alcohol, that indubitably is misuse. This misuse falls into five categories according to attendant circumstances.

The first type of misuse is prolonged use of barbiturates in slightly excessive amounts. Some individuals may be of such unstable personality as to rely upon barbiturates to enable them to face the real or fancied tension of their daily lives. Thus, because barbiturates afford relief from anxiety, tension, and conflicts, they lend themselves to habitual self-medication at a slightly increased dosage, particularly in disturbed states for which there is no specific therapy.

Second, barbiturates may be misused as a substitute for narcotics or

alcohol. Narcotic addicts who are temporarily unable to obtain the narcotic of their choice may turn to barbiturates. Alcoholics may resort to barbiturates to relieve the tremor and nervousness following a drinking episode. Another variety of misuse in this category is the ingestion of barbiturates following drinking of alcohol; or vice versa. Large doses of barbiturates may be taken inadvertently during a period of alcoholic intoxication. Then too, some individuals deliberately combine alcohol and barbiturates to obtain a brief but intense exhilaration, which is of course followed by profound intoxication and narcosis. This is a highly dangerous practice; for, as pharmacologists have repeatedly warned, these drugs in combination have a potentiating action which magnifies the effects of each.

The remaining three categories have to do with episodes of overdosage of barbiturates which occur either accidentally or intentionally. A person who wants only to obtain rest during a period of extreme stress may take an excessive amount of a barbiturate. Usually he is seeking a quick and full effect; he wants to make sure that he will fall into a deep sleep without delay. Perhaps he subscribes to the old adage that if a little is good, a lot is better. At the same time he is unfamiliar with the dangers of barbiturates. As a result he may increase the dosage and consume a quantity far in excess of that required to produce a night's sleep.

More frequently an unintentional overdose occurs because a person ingests additional doses after failure of the usual hypnotic dose to produce sleep. After a person takes one or two sleeping pills, he may enter into a twilight zone of mental confusion and forgetfulness instead of dropping off to sleep. In this state he forgets that he has already taken the pills; he takes more. Thus, he accidentally ingests excessive amounts of barbiturate while he is in a semi-stuporous state induced by the original dose. This sequence is known as automatism.

In addition to these episodes of overdosage which are purely ac-

Report on Barbiturates

CURRENTLY there is a clamor and outcry in the press about the widespread misuse of barbiturates with reports of accidental deaths and demands that these drugs be placed under strict control. This is not a new complaint. It was in response to just such a note of alarm that 13 years ago the Committee on Public Health of The New York Academy of Medicine first deliberated on the value of barbiturates, the dangers of their misuse, and proper measures for their control. Two years later it formulated a code that set the pattern of control, a pattern that has been widely adopted. Now a rising chorus of protest over the existing situation has prompted the committee to reexamine the problem of barbiturates.

Definition

The barbiturates comprise a family of many chemical compounds of which barbituric acid is the parent. Some 33 years ago one of the derivatives was introduced into therapy under the name of veronal. Since then by substitution of an aliphatic or aromatic group, barbituric acid has yielded a large number of derivatives. Many have proved to be therapeutically useful.

Each of these has a chemical name; in addition, it has either a popular name or a registered trade name. Since barbiturates are members of a series, all have essentially the same pharmacological and therapeutic action, but each shows an individuality. Hence, there are preparations containing two or more barbiturate derivatives; each such mixture is usually marketed under a registered proprietary name. Furthermore, pharmaceutical manufacturers have added a small amount of barbiturates to mixed preparations in which they are not the main ingredient. It is said that the number of products containing barbiturates, including single, multiple, and mixed ingredients, now exceeds 275.

Use of Barbiturates

The therapeutic uses of the barbiturates are several: hypnotic, sedative, anticonvulsant, anesthetic, and adjuvant with analgesics. Thus, one or more of these substances is the active principle in sleeping pills and in some of the tension-reducing preparations. They are, however, not to be confused with the newer so-called tranquilizing drugs such as rauwolfia or chlorpromazine. (Some of the newer tranquilizing drugs

which are growing in popularity as substitutes for the barbiturates may have similar hazardous effects. They have not been considered in this report because their use is as yet too brief to warrant an authoritative statement.) The barbiturates are also an almost indispensable therapeutic agent for the control of convulsions in epilepsy. Each drug in the barbiturate group is marketed and dispensed as an individual preparation; some are included in multi-ingredient prescriptions and products. As a group the barbiturates are rated among the 10 most valuable drugs available to physicians.

Their value is reflected in the extent of their use. In view of their properties it is perhaps not too surprising that the production and sale figures are very high. The total national production of barbiturates has shown a steady increase since World War II. In addition to their increased use as hypnotics, it is believed that pharmaceutical manufacturers more and more are incorporating small sedative doses of barbiturates in mixed preparations. Idestrom states that in the United States in 1948 the estimated consumption was 336 tons or 24 doses of 0.10 gm. per person as compared with an estimated consumption in 1952 in Sweden of 20 tons or 29 doses of 0.10 gm. per person.

From a study in 1954, Fazekas and Koppányi assert that between 3 and 4 billion doses of barbiturates are legally prescribed by the medical profession in the United States annually. Assistant Commissioner Trichter of the New York City Health Department estimates that 12 percent of all prescriptions compounded by pharmacists in this city contain one or another of the barbiturates. They are also dispensed

In view of the national interest in commerce in barbiturates, Public Health Reports reprints from the June 1956 Bulletin of The New York Academy of Medicine the report of its Committee on Public Health. The report was prepared by the Subcommittee on Barbiturates: Haven Emerson, M.D., chairman, Henry Aranow, Jr., M.D., George Baehr, M.D., McKen Cattell, M.D., Hubert S. Howe, M.D., Lawrence C. Kolb, M.D., Robert W. Laidlaw, M.D., J. Murray Steele, M.D., H. D. Kruse, M.D., secretary. It was approved by Edward J. Donovan, M.D., president of the academy.

effects. Only low grade tolerance is developed under such circumstances; therefore the tendency to increase dosage to obtain adequate effects is minimal. This is a sharp point of distinction between barbiturates and opiates. Although psychic dependence on these substances may develop, it is believed not to be injurious. It is like habituation to coffee or tobacco. From these observations it is the belief of the Committee on Public Health that the habitual daily use of barbiturates at therapeutic levels, even for long periods, is not perforce injurious. It should not be necessary to add that this pronouncement does not connote approval of or condone the use of barbiturates for whatever length of time without valid reason and medical supervision.

Like almost every form of medication, barbiturates when misused are capable of producing toxic effects and even death. Through regular, prolonged use of barbiturates in excessive amounts chronic intoxication develops. The symptoms of this toxic cumulative action are mainly mental, psychic, and neurological. Specifically, these manifestations are: muscular incoordination, slurred speech, inability to perform skilled acts, as well as mental symptoms, such as confusion, abnormal behavior, impaired judgment, and possibly hallucinations.

Acute intoxication results from an overdose, either accidental or suicidal, on a single occasion. It may be mild, moderate, or severe in degree depending upon whether the person remains conscious, or becomes semicomatose, or comatose. Mental and neurological disturbances are the principal symptoms. In the severe form unless prompt and energetic therapeutic measures are instituted, the outcome may be fatal. The degree of intoxication and the issue depend on the type of barbiturate, the dosage, and the patient's constitution and physical status.

Prevalence of Misuse

It is difficult to derive accurate figures on the total prevalence of misuse of barbiturates because data in one or more categories are un-

trustworthy or unobtainable. For example, the general public seems to be familiar with the sedative and somnifacient effects of barbiturates; but no one can state reliably how many persons are obtaining barbiturates illegally and taking them in the usual or slightly higher sedative or hypnotic dose without medical supervision. (Where rates are reported, they are based on per million population, total, male, or female.)

Addiction. Reliable data indicating the extent of true addiction, that is, prolonged daily ingestion of very large quantities of barbiturates, are not available. Despite the total quantity of barbiturates used, the figure for addiction is believed to be insignificant; for, addicts are not frequently encountered. Addiction is probably limited to persons who, if the barbiturates were not available, would take excessive quantities of alcohol or other drugs.

Of 919 barbiturate poisonings in New York City in 1954, 36 were said to be in barbiturate addicts.

Poisonings. Due to inadequate report procedures the prevalence of chronic poisoning is not known. Data are therefore exclusively on acute poisonings. These may be conveniently classified under the headings nonfatal and fatal.

Nonfatal poisonings. Not all cases of barbiturate poisoning are fatal. The nonfatal cases may require treatment in a hospital. It is reported that in England and Wales the number of cases requiring hospital treatment has increased in recent years. In the United States about one-fifth of all instances of drug poisoning are due to barbiturates. It is estimated that 1 in every 2,000 admissions to hospitals is for acute barbiturate poisoning.

Figures on the incidence of nonfatal poisonings in New York City since 1945 are available by years. Under article 7, section 86 of the Sanitary Code of New York City it is the duty of persons in charge of hospitals and of physicians to report poisoning, whether acute or chronic, by drugs due to self-medication or on prescription. The nonfatal poisonings are reported to the

bureau of preventable diseases of the New York City Department of Health and from there to the poison center of the department. The rate of total nonfatal poisonings, including both categories, has risen steadily in New York City from 1945 to 1954. Indeed, it has more than doubled over that period. The rate was 35.4 for 1945; it reached 61 in 1948; and became 97 in 1954.

Nonfatal poisonings comprise two categories: poisonings under accidental or undetermined circumstances, and unsuccessful suicidal attempts. Locket and Angus, reviewing 64 consecutive cases entering Oldchurch Hospital in England in the 4 preceding years, found that 49 at least were suicidal attempts. Moreover, of all cases of attempted suicide admitted alive during the 4 years, barbiturates were the chosen agents in more than 80 percent.

Analysis of the rates of nonfatal poisonings in New York City between 1945-54 reveals that unsuccessful suicidal attempts constituted the major category every year, sometimes by a ratio of 2:1. The rate for attempted suicide was 22.4 per million living population in 1945; it became 42 in 1948; it rose to 58 in 1950; it dropped to 37 in 1952; and returned to 57 in 1954. In contrast, the rate for accidental and undetermined nonfatal poisonings did not exceed 20 per million population until 1949; it became 30 in 1953; and 40 in 1954. It is apparent that the rate of total nonfatal poisonings has increased and that unsuccessful suicidal attempts contribute the major portion.

Fatal poisonings—total deaths. The data on deaths from barbiturate poisoning are much more reliable than those on morbidity. Figures are available for England and Wales, the United States, and New York City.

For England and Wales the rate of total deaths from barbiturate poisonings was 1.36 in 1939, and remained between the range of 1.7 to 2 until 1945 when it became 2.5. Thereafter it has increased steadily to become 13 in 1954 (fig. 1). If the 5-year period from 1930-43 is compared with a later period of similar

cidental or inadvertent, in others the intent is suicide. Hence, barbiturates are misused as a means of self-destruction. Indeed, they are a popular choice. Yet judged by their relative effectiveness, it is a less perfect choice for the purpose than numerous other methods. Nevertheless, it represents the gravest misuse of these valuable drugs.

In sum, whatever the motive and attendant circumstances, persons may increase the amount of barbiturate ingested to the point where an episode of acute poisoning occurs. Not infrequently it terminates fatally.

Effects of Misuse

The effects of misuse of barbiturates may be considered under three headings: habituation and addiction; chronic intoxication; acute poisoning. Because barbiturates afford relief from anxiety, tension and conflicts, they lend themselves to habitual use, especially since there is no specific therapy to supersede them. There is a difference of informed opinion as to whether they should be termed addicting or habituating drugs. It may be helpful to consider a definition of terms.

To most laymen the word "addiction" simply means a bad habit. To experts it means more than that, but they differ on its definition. According to pharmacologists the significant element in addiction is dependence, either physical or emotional. Tatum and SeEVERS have defined addiction as "a condition developed through the effects of repeated actions of a drug such that its use becomes necessary and cessation of its action causes mental or physical disturbances." However, Isbell and Fraser do not regard this definition as acceptable to physicians and social workers who have to handle addicts. They state that the concern about addiction is "not because individuals who use drugs become dependent but because the effects of the drug are harmful both to the individual and society." This view is reflected in Vogel, Isbell, and Chapman's definition of drug addiction "as a state in which a person has lost the power of self control with reference to a

drug and abuses the drug to such an extent that the person or society is harmed."

In their review of the subject, Isbell and Fraser state that the Drug Addiction Committee of the National Research Council reached a definition of drug addiction which represents a compromise between a formulation based on dependence and that based on harm to the individual or society. It is: "Addiction is a state of periodic or chronic intoxication, detrimental to the individual and to society, produced by the repeated administration of a drug. Its characteristics are a compulsion to continue taking the drug and to increase the dose with the development of psychic and, sometimes, physical dependence on the drug's effects. Finally, the development of means to continue the administration of the drug becomes an important motive in the addict's existence."

Isbell and Fraser then point out that physical dependence is not an essential part of this definition; and that psychic dependence, although a necessary, is not a specific and distinctive characteristic. In their opinion the latter adds nothing to the definition. They express their preference to return to their original position in defining addiction "as a state of periodic or chronic intoxication in which an individual compulsively abuses a drug to such an extent that the individual or society is harmed."

While agreeing that an addicting drug produces harm to an individual or society, the committee would place emphasis on dependence and, for purposes of differentiation, particularly on physical dependence. Perhaps the best way to understand addiction is to distinguish it from "habituation." "Habituation," so far as the use of drugs is concerned, signifies an emotional dependence resulting from repeated use; administration of the drug may be discontinued without disturbance of bodily functions. In contrast, "addiction" is considered to be an altered condition of the cells, tissues, and organs of the body, brought about by the continuous administration of a drug; cessation of use causes painful physi-

cal as well as mental disturbances. In brief, habituation refers to the condition in which psychological stress appears upon abstinence; while addiction pertains to the condition in which physical signs also occur upon withdrawal.

Vogel, Isbell, and Chapman assert that barbiturates fulfill all three criteria of addiction: development of tolerance, habituation, and physical dependence. They report that when barbiturates are withdrawn abruptly from patients who have been taking 12 gr. or more daily for several weeks, convulsions and acute psychotic reactions appear. From these results they are emphatic in declaring that the derivatives of barbituric acid are addiction-producing drugs since they can bring about not only psychological but also physical dependence. It would appear therefore that physical withdrawal symptoms occur when large amounts of barbiturates have been ingested over a period of time. Under these conditions it is probably accurate to refer to barbiturate addiction.

The Expert Committee of the World Health Organization, after considering the problem, concluded "that the barbiturates must be considered drugs liable to produce addiction, [and] dangerous to public health, although differentiation among them with respect to the intensity of this liability cannot be made at this time."

After weighing all the evidence it is the opinion of the Committee on Public Health that true addiction manifested by physical dependence with withdrawal symptoms may follow prolonged high dosage of barbiturates. But, the committee emphasizes that the symptoms of addiction with barbiturates are produced only under these specific conditions; and that these conditions do not commonly occur.

Of equal if not greater concern is the question relating to potential dangers of prolonged ingestion of barbiturates in small amounts. It may be pointed out that the habitual daily use of small or moderate doses of barbiturates under medical supervision has been continued for many years without evidence of harmful

Figure 2. Deaths from barbiturates in the United States, 1939-54, rate per million population.

United States, 1.65 to 2.27; New York City, 3.1 to 8.2. It may be seen that in England and Wales the rate increased almost fivefold; in the United States, $1\frac{1}{2}$ times; and in New York City, $2\frac{1}{2}$ times.

Comparing the three sources of data over the years 1939 through 1954 the rates were highest in New York City (fig. 4). Up to 1950 the rates were higher and thereafter lower for the United States than for England and Wales.

The sex distribution of rates for fatal barbiturate poisoning under accidental circumstances in the data of England and Wales shows a higher figure for females for all except 4 of the 16 years (fig. 1). In 1939 the rate was 0.2 for males, 0.5 for females; in 1954, 3.2 for males and 5.1 for females. The average rates for the period 1949-53 were: male, 2.5; female, 3.3. During that period in the United States the rates for both sexes declined (fig. 2). In 1949 they

were 2.9 for males and 3.4 for females; in 1953 they were 1.9 for males and 2.3 for females.

For New York City from 1939 through 1943, the rate for males fluctuated narrowly between 2.5 and 3; it became 6.0 in 1944, and from 1946 through 1953 it was within the range 7.7 to 9 except for 1950 when it was 11 and 1952 when it was 11.5 (fig. 3). The rate for females from 1939 through 1953 had a general trend upward but it fluctuated with peaks at several points. From 1939 through 1941 it did not exceed 2.9; over the next 3 years it ranged between 4.4 and 5.4; it had peaks of 11.8 in 1946, 9.1 in 1950, and 12.5 in 1952; then dropped to 8.4 in 1953. The male rate was in excess of the female rate for 10 of the 16 years, but the course was irregular. The averages for the period 1949 to 1953 were: male, 9.5; female, 8.6.

From 1918 to 1930 accidental and undetermined fatal poisonings from

morphine exceeded in absolute numbers those from barbiturates. After that period a reversal in the ratio occurred. For example, in 1922 the ratio was 5:1 with morphine predominant. In 1954 the ratio was likewise 5:1 but barbiturates were predominant.

Deaths from suicide by barbiturates. In England-Wales during the period from 1939 through 1954, the suicide rate by all methods tended to fluctuate within a narrow range without showing a definite upward or downward trend. The rate for suicide from barbiturate poisoning, however, after having remained fairly uniform up to 1945, then underwent a rapid rise (fig. 1). Starting at 1 in 1939, the rate became 1.4 in 1945 and reached 8.8 in 1954. If the 5-year period from 1939 through 1943 be compared with a later period of similar length, 1950 through 1954, the average rate of deaths by suicide increased sevenfold, from 1 to 7.1 per million.

In the United States the suicide rate from barbiturate poisoning fluctuated from 1.6 to 2.6 from 1939 to 1944, inclusive; thereafter it rose steadily to reach a level of 4.5 during 1949 and 1950; it declined slightly during the next 3 years and then moved upward to 4.4 in 1954 (fig. 2). The average rate for 1950-54 was double that for 1939-43; 4.2 compared with 2.

In New York City from 1939 through 1943, the rate for suicide by barbiturate fluctuated narrowly between 3.2 and 5; it jumped to 12 in 1944 and moved rather unevenly to reach 22.8 in 1954 (fig. 3). The average rate for 1950 through 1954 was almost 4 times that for 1939 through 1943; 16.1 as against 4.3 per million.

Upon comparing the three sources of data over the 16-year period 1939 through 1954, the rates are found to be in the following ascending order: the United States, England-Wales, New York City (fig. 4). For the last 5 years of that period the average rate for England-Wales has been 1.7 times that for the United States; that for New York City has been 2.2 times that for England-Wales and 3.8 times that for the

length, 1950-51, the average rate of fatal poisonings during the latter shows a sixfold increase, 1.8 versus 10.5.

In the United States the rate for total deaths from barbiturate poisoning was 3.23 in 1939, and remained in a range not exceeding 4.3 until 1945 when the rate was 5.7. It reached 7.6 in 1949; thereafter it declined and has remained between 6 and 6.5 from 1951 through 1954 (fig. 2). If the average rates for two 5-year periods are compared, 1939-43 and 1950-54, it is found that the figure for the later period is slightly less than twice as high, 3.6 versus 6.5.

For New York City the rate was 5.7 in 1939; it gradually increased to 9 in 1943; it jumped to 17.7 in 1944; it reached 27.3 in 1950; it declined slightly over the next 3 years; and then rose to 25.9 in 1951 (fig. 3). The average rate for the period 1950-54 was 24.3; it was 3 times

higher than the average rate of 7.4 for the earlier span, 1939-43.

Comparison of the three sources of data reveals that the rate for total deaths from barbiturate poisoning was higher in New York City for every year from 1939 through 1954 than were the rates for either England-Wales or the United States (fig. 4). From 1939 to 1949 the rate for the United States was higher than that for England-Wales. Thereafter the reverse was true. For 1954 the rate for England-Wales was about twice as high as that for the United States. The comparative order of average rates for 1950-54 was: United States 6.5; England and Wales 10.5; New York City 24.3.

For both males and females in England and Wales the rate of fatal poisonings has risen steadily from 1939 through 1954 (fig. 1). Except for one year, the rates for females were slightly higher. The average rates for the period 1949-53 were:

male, 8.1; female, 10.2. Figures on the distribution of fatal poisonings by sex in the United States are available only from 1949 through 1953. During that period the rates for both sexes declined; the rates for females were slightly higher than for males (fig. 2). The average rates were: male, 5.7; female, 7.7.

Until 1944 the rate for fatal poisonings for males in New York City ranged between 6 and 7.7; in 1944 it jumped to 17; in 1950 it reached a high point of 27.7; and declined thereafter to a value of 23 in 1953 (fig. 3). The rate for females was 5.3 in 1939 and increased steadily until it reached 10.7 in 1942; it jumped to 18.4 in 1944; and reached its peak of 31.3 in 1946. For the next 7 years it fluctuated rather narrowly between 20.3 and 23.1 except for the year 1950 when it was 27. Up to 1948 the female rate was higher than the male but thereafter the male has been higher. The average rates for the 5-year period 1949 through 1953 were: male, 24.4; female, 23.2.

Fatal poisonings comprise two categories: death under accidental or undetermined circumstances and suicide.

Death under accidental circumstances. For England and Wales the rate for accidental death from barbiturate poisonings was 0.3 in 1939, and rose gradually to become 4.1 in 1954 (fig. 1). For the United States the rate for fatal barbiturate poisonings under accidental circumstances was 1.5 in 1939; it remained at approximately that level until 1945 when it reached 2.8; its high point was in 1949 with a rate of 3.1. In 1951 it declined and from 1952 to 1954 it was 2.1 (fig. 2).

The trend of rates for New York City over the same period has been highly irregular (fig. 3). The rate for fatal poisonings under accidental circumstances was 2.4 in 1939; it reached three peaks of 10.1, 10, and 12 in 1943, 1950, and 1952 respectively; and then dropped precipitately to 3.1 in 1954. For each of the three census areas the average rate of the period 1939-43 compares with that of 1950-54 as follows: England and Wales, 0.74 to 3.34;

Figure 1. Deaths from barbiturates in England and Wales, 1939-54, rate per million population.

fatal and nonfatal, from 1945 to 1954 inclusive, it is found that the rate was 57.6 in 1945; it increased steadily until it reached 111.1 in 1950; for the next 3 years it was below 100; but in 1954 it reached the peak of 123.3 per million living persons. The rate for 1954 was more than twice that of 1945. Of 491 cases of barbiturate poisoning in

New York City studied by occupation, 40 percent were in housewives, theatrical performers, clerks, unemployed and factory workers with housewives leading all others combined in this group by almost 2 : 1.

The total rate may be separated into two categories: nonfatal and fatal poisonings under accidental and undetermined circumstances; attempted suicide and suicide. It is interesting to examine the composition of this total rate to ascertain the trend and proportion of each component.

Nonfatal and fatal poisonings under accidental circumstances. Barbiturate poisonings under accidental circumstances, both nonfatal and fatal, in New York City have shown an upward trend with some fluctuation over the 10-year period 1945-54. The rate in 1945 was 21.4; in 1954, 43.4. Thus, over this span the rate has more than doubled.

Attempted suicide and suicide. The rate for attempted suicide and suicide from barbiturate poisoning in New York City was 36.2 in 1945; it increased steadily to reach 75.7 in 1950; it declined during the next 2 years; and then resumed its climb to reach 79.8 in 1954. Here again the rate over the 10-year span has more than doubled.

For every year from 1945 through 1954, the rate for combined suicidal attempts and suicide was greater than that for combined nonfatal and fatal poisonings under accidental circumstances. In four of the years the rate was more than twice as high for attempted suicide and suicide than it was for poisonings under accidental circumstances. Over the 5-year period, 1950-54, almost two-thirds of the barbiturate poisonings, both fatal and nonfatal, were by self-destructive intent rather than by accident.

Source of Supply

It is abundantly clear that there has been an increase in the use of barbiturates; it is equally apparent that it has been accompanied by an increase in the misuse of them. But there is sharp difference of opinion over the source of supply which contributed to the misuse. It is con-

Figure 4. Deaths from barbiturates in New York City, United States, and England and Wales, 1939-54, rate per million population.

United States. In 1939 Hambourger noted that in the United States the incidence of suicides was nearly twice as high in large cities as in the whole Nation.

The sex distribution on the suicide

rate by barbiturate poisoning for England-Wales shows that for the period 1939-54 the rates for female suicides have with the exception of 1 year been higher than those for the males. The average rates from 1949

through 1953 were: males, 5.6; females, 6.9. Contrastingly, when total suicide rates by all methods are considered, the male rates have been consistently in excess of the female. From 1949 through 1953 in the United States the rates for barbiturate suicides for the females were consistently slightly higher than for the males. The averages were: males, 3.4; females, 5. The distribution by sex of the suicide rate from barbiturate poisoning in New York City from 1939 through 1953 does not show a consistent trend. The averages for the period 1949 to 1953 were: male, 14.9; female, 14.6.

From a study of the England-Wales data Brooke found that the increase in suicide rates from barbiturate poisoning from 1942 to 1954, inclusive, was more pronounced at ages 45 and upwards. In the age group 45-64 the rates for 3 years by sexes were: 1942, males, 1.6, females, 1.5; 1948, males, 7.3, females, 8.6; 1954, males, 14.9, females, 18.1. The rates in the age group 65 and over were: 1942, males, 0.6, females, 0.4; 1948, males, 5.1, females, 6.3; 1954, males, 12.8, females, 24.4. It was remarked that it was in these age groups that one would expect to find most of the cases of depression and insomnia for which barbiturates might be prescribed.

The distribution of the death rate from barbiturate poisoning on the basis of attending circumstances yields striking results. Of the average death rates from barbiturate poisoning during 1950 to 1954, inclusive, in England and Wales, the United States, and New York City, the percentages due to suicide were respectively: 67.6, 61.6, and 66.2. Thus in all three areas suicides account for about two-thirds of the deaths from barbiturate poisoning.

From the England-Wales experience, Brooke commented that a preference has been shown lately for using barbiturates as suicidal agents rather than some other lethal means. This is likewise true in New York City where of recent years barbiturates have become the method of choice for suicide.

Total poisonings, nonfatal and fatal. From the data on total poisonings in New York City, both

Figure 3. Deaths from barbiturates in New York City, 1939-54, rate per million population.

the retail pharmacist is said to dispense barbiturates without a prescription. Where there are legal provisions which require the pharmacist to keep records on the purchase and distribution of barbiturates, these violations are detectable and subject to prosecution. However, the inadequacy of enforcement even in these areas makes the figures on violations extremely unreliable.

The second source of supply without a prescription is from friends and neighbors who usually act from a motive of helpfulness. When a person complains of insomnia or anxiety, a well-intentioned friend with a similar complaint may provide barbiturates out of his supply.

The third source of supply of barbiturates, it is asserted, is illegal traffic with a black market. By some this is regarded to be the major source of supply of barbiturates and responsible for most of the potentialities of misuse. It is alleged to be a vast, gigantic operation. In an article on the subject the *New York World-Telegram and Sun* detailed the four channels which operate outside the usual pharmaceutical routes. First in the illicit trade are export-import firms which obtain their supply from the wholesale druggist. All that the export-import firm needs is a letterhead and a telephone number; for these may be the only credentials on which the wholesaler checks. A second type of illicit operation is by deception and misrepresentation in which supply houses and even pharmaceutical houses are the victims. A person interested in peddling barbiturates at a fantastic profit has a fictitious physician's letterhead or prescription blank printed and on the basis of it places orders with supply houses. The third source of supply which is said to fall into illegal channels is samples for physicians. Reputedly there are 200 different brands of sleeping pills and 1,300 drug houses compound and package one or more preparations. In order to encourage the sales of their products, these companies regularly send samples to physicians. A widespread amount of these products is

said to contribute to the vast illicit traffic.

On the other hand, this image of a vast illegal traffic is not shared by all authorities. Some assert that there is no evidence of production of barbiturates in the United States designed exclusively for illicit sale. They add that although the extent of diversion of barbiturates from legitimate to illegitimate channels is unknown, the infrequency of charges of this practice would lead to the belief that it is comparatively small.

Previous Recommendations

In 1943 in the belief that barbiturates were being sold indiscriminately, the commissioner and deputy commissioner of health of New York City requested the Committee on Public Health to consider the subject and to recommend a solution. At that time the Sanitary Code of New York City included barbiturates among the harmful drugs which could not be dispensed without a written prescription. It further provided that any prescription containing barbiturates should not be renewed or refilled by a pharmacist if it bore any indication to that effect.

The health department was of the opinion that in the indiscriminate use of barbiturates the supply was from two sources: (1) over-the-counter sale by pharmacists; (2) refilling of prescriptions by pharmacists. As a possible control of the second source the deputy commissioner suggested an alternative: (1) to prohibit the refilling of all prescriptions containing barbiturates, a procedure that admittedly might be highly unpopular; or (2) to undertake an educational campaign among physicians to make more frequent use of their prerogative to limit prescriptions to a single filling. The opinion of the Committee on Public Health was sought concerning the desirability of these proposals.

The committee stated its belief that it was inadvisable to prohibit the refilling of all prescriptions containing barbiturates since such a

policy would work an undue hardship on those patients who might be required to use barbiturates continuously; for example, epileptics. As for the alternative course of action, the committee doubted whether physicians should be asked to antagonize patients by writing "nonrefillable" on prescriptions inasmuch as the physicians' motives would certainly be misconstrued.

The committee recognized two other methods by which the sale of barbiturates might be further controlled: (1) the Sanitary Code might be revised to provide that prescriptions for barbiturates should not be refillable unless the physician indicated otherwise; and, (2) prescriptions for barbiturates might carry an expiration date of 6 months or perhaps a year. Exceptions might be made for prescriptions in which the barbiturate was not the main ingredient.

After consideration of all the aspects, the committee reached the conclusion that the use of barbiturates did not then constitute a sufficient problem in public health to warrant the adoption of any measures for restriction beyond those then in the Sanitary Code. It was believed that the production of barbiturates was not unduly large in view of the number of epileptics. Moreover, the committee reasoned, further control of the sale of barbiturates would not materially reduce the number of suicides, since a person bent on self-destruction by barbiturates could go from physician to physician in order to obtain a sufficient quantity or could resort to other methods of suicide. The committee summarized its position: "In view of the fact that the barbiturates do not present a large public health problem from the point of view of suicides, toxic psychoses, addiction, or chronic poisoning, and since the suggestion for the further control of their sale by the department of health would either work a hardship on those who must use these drugs almost continuously, or would place physicians in an unnecessarily difficult position, or would prove unenforceable, the committee is of the opinion that no revision in the Sanitary Code should

venient to consider this issue over the source under the headings: misuse of a prescription, and misuse without a prescription.

Misuse of prescription. To be considered under this topic is the charge that many of the prescriptions for barbiturates are unwarranted, ill-advised, or contraindicated. This point has already been discussed under promiscuous use. The extent to which prescriptions include barbiturates was also cited there. It has been pointed out that from such information as is available the physician is prescribing barbiturates justifiably for symptomatic relief in patients who have actual complaints, and that if specific remedies were available he would gladly turn to them.

Sleeplessness and tension are probably the two most frequent complaints for which the physician prescribes barbiturates. Locket and Angus report that in 62 out of 61 cases of barbiturate poisoning, the barbiturate was prescribed for the patient by his medical practitioner; and in more than 90 percent it was given for insomnia either alone or as the major complaint. Certainly such a therapeutic measure by a physician is neither irrational nor unwarranted. On the contrary, the physician is performing his professional duties by the best method available to him.

Another part of the same charge concerning prescriptions for barbiturates is based on their being a source of supply for suicides. Of the 64 patients with barbiturate poisoning reported by Locket and Angus, 49 were suicidal attempts; 9 had made one or more previous attempts. Nineteen were diagnosed as having a severe depressive state; 12 had severe social and domestic disturbances. Some of the patients had previously been in mental hospitals. All had obtained barbiturates by prescription. On studying the source of supply in 718 cases of barbiturate poisoning in New York City, Trichter found 52 percent had obtained the barbiturate on prescription from a physician.

In these instances, critics question whether the prescriptions for bar-

biturates were not ill-advised and contraindicated. The inference is that the physician may have exercised poor judgment and failed to establish adequate precautions. A fair, pertinent, and significant question is: What would have happened to patients who committed suicide by a barbiturate if the physician had not prescribed it? It is not improbable that they would have obtained it from another source or would have chosen another means of self-destruction.

This opens up the entire subject of suicides, not just those from barbiturates. It is beyond the scope of this report to go into that subject in all its ramifications. But for present purposes it should be stated that some patients may give no indication of contemplated self-destruction. Furthermore, when patients issue threats or declare intentions, they seldom utter them in the presence of the physician, and the family either dismisses them or fails to transmit the information. Consequently, all too frequently the physician is not alerted to the possibility of suicide. Moreover, not all persons who issue threats carry them out. Thus it is not easy to reach a decision about the probability of suicide in a patient. Nor is the course of preventive action simple and unobstructed. The patient, or the family, or both, may resist recommendations of supervision and institutionalization. What is virtually demanded is an infallible method of detecting prospective suicides and of thwarting their plans, often without recourse to hospitalization. This, the physician does not have. Yet he must try to bring relief to patients from their complaints. When the situation is viewed in its broad frame, it is at least an open question whether the physician's prescription for a barbiturate to relieve insomnia, anxiety, or tension is ill-advised or contraindicated on the grounds that the patient might commit suicide.

The second type of alleged misuse of prescriptions for barbiturates is the charge that the therapeutic prescription from the physician is very often for amounts beyond the immediate need of the patient. It is probably true that in an attempt to re-

lieve the patient of expenditure of time and money in repeated office visits, the physician may issue prescriptions for barbiturates in excess of the patient's immediate need. Unfortunately, some patients either cannot or will not exercise due judgment in taking the medication as directed; some may save their pills for suicidal purposes. The *Lancet* has reported on two persons who committed suicide, both of whom had been given a fortnight's supply of barbiturates. One had received 72 tablets 10 days before his death, of which only 4 remained. There are no data to indicate the frequency with which physicians prescribe barbiturates in unreasonably generous amounts.

As a third type of misuse of prescriptions it is said that pharmacists and physicians collaborate in dispensing barbiturates indiscriminately but technically in a legal manner. It is asserted that the pharmacists sell barbiturates to persons with no prescription at the time of sale but subsequently the transaction is covered by a collaborating physician who provides a prescription without seeing the patient.

In the fourth type of misuse of prescriptions, the pharmacist is alleged to dispense barbiturates beyond the amount specified in the prescription. Commenting on the seeming unreasonableness of having to return later for an additional supply, the customer asks whether a greater amount than specified in the prescription can be sold. It is conceivable that some pharmacists may yield to accommodating the customer by meeting his request.

At present there are no figures to indicate the number of instances in which these various types of misuse of prescription occur. By some there is said to be flagrant abuse and that it constitutes a considerable source of supply for potential misuse. Others regard this source of supply as negligible.

Without a prescription. In considering source of supply there is another category comprising the various ways in which barbiturates are obtained without a prescription. Three different types of procedure fall under this heading. In the first,

and in the main duplicated section 1360a of the 1939 law. The basic requirement was a written prescription. In 1946 section 1360a was newly entitled "Barbiturate and Other Hypnotic and Somnifacient Drugs" and was expanded to essentially its present form. In 1947 following a new revision of the Education Law, section 1360a was renumbered to section 6814. Minor changes were made in the phraseology of the section; and numbering of the subsections was standardized.

Section 6814 has continued to the present without change. It is dissimilar to the committee's recommendations in several respects:

1. It permits a prescription for barbiturates to be refilled unless it bears a direction to the contrary. If the prescriber fails to specify "not to be refilled" or an indication of the refillable time period, then the prescription may be refilled during a period of not more than 6 months. Furthermore, the prescription shall not be refilled prior to the end of the period for which the medication should last.

2. It carries no provision for the physician to dispense barbiturates directly to the patient.

3. It contains no provision requiring the pharmacist to keep records of bills for purchase of barbiturates; and,

4. It does not require manufacturers, wholesalers, and jobbers to maintain a record of amounts of barbiturates received, distributed, or sold.

Section 1747b of the Penal Law of New York State entitled "Sale or Possession of Barbiturate Drugs or Preparations" carries a penalty for unauthorized sale or possession of barbiturate drugs or preparations.

Other States

The Drafting Committee of the Council of State Governments drafted a model bill entitled "Hypnotic or Somnifacient (sleep-producing) Drugs Act" which appeared in its report on Suggested State Legislation Program for 1955. The council is the research and law writing agency of the Conference of State Governors which is held an-

nually to consider methods of achieving greater economy and efficiency in State government. This model law is similar to the recommendations by the Committee on Public Health except in the following particulars: Although it requires that refilling of a prescription must be specifically authorized, it does not specify a minimum interval between renewals, the total number of renewals, and the expiration date of the prescription. On the other hand, it includes a section on penalties. One of the provisions in the model law is similar to that recommendation of the Committee on Public Health which was not adopted in the Sanitary Code; namely, the physician must maintain records of barbiturates distributed by him.

In response to a questionnaire on the model law, the council heard from 34 out of 48 States. Alabama, California, Iowa, Maine, New Jersey, North Carolina, South Carolina, Texas, and Wisconsin indicated that legislation substantially similar to the draft of the model law was approved in each State prior to 1955. Indiana, Massachusetts, Montana, Nebraska, and Rhode Island have indicated that legislation substantially similar to the model act was passed during the 1955 legislative sessions.

Federal

Federal control over the sale of barbiturates is exercised by the United States Food and Drug Administration through application of the misbranded drug and device provisions of the Federal Food, Drug and Cosmetic Act of 1938, sections 502 and 503. Prior to 1951, Food and Drug Administration prosecutions for the sale of barbiturates without prescription rested on the charge of misbranding under section 502 which specified 10 types.

Of these the following four covered in section 502 (b), (d), (e), and (f) should be especially considered: A drug and device in packaged form shall be deemed to be misbranded:

1. Unless it bears a label containing the name and place of business of the manufacturer, packer, or dis-

tributor; and an accurate statement of the quantity of the contents.

2. Unless the label on a narcotic or hypnotic substance bears its name and quantity; and the statement "Warning—May be habit forming." By the terms of the section barbiturates are defined as habit forming.

3. If it is not designated solely by a name recognized in an official compendium, unless its label bears the common or usual name of the drug or each active ingredient, including the quantity or proportion of substances specified in the subsection.

4. Unless its labeling bears adequate directions for use and such adequate warnings against use in instances where it may be unsafe. Under the accompanying regulation of this fourth provision, shipment or delivery of prescription drugs, including barbiturates, were exempted if the label contained the statement "Caution: Federal law prohibits dispensing without prescription."

Section 503 (b) of the Federal Food, Drug and Cosmetic Act of 1938 provided that drugs dispensed on prescription were exempt from the first and third labeling requirements. This section further provided that if the prescription was marked non-refillable or refill was prohibited by law, the drug dispensed was exempt from the requirements that the label carry the name and quantity of narcotic or hypnotic substance, and the statement "Warning—May be habit forming."

In 1951 section 503 (b) was amended by the so-called Durham-Humphrey Act which replaced the previous provisions of that section. This new section provides essentially that:

1. A drug intended for use by man which:

- (a) is a habit-forming drug to which section 502 (d) applies [narcotic and hypnotic substances]; or

- (b) because of its toxicity or other potentiality for harmful effect, is not safe for use except under supervision of a practitioner licensed by law to administer such a drug; or

- (c) is a new drug limited to use under the professional supervision of a practitioner licensed by law to

be recommended at the present time."

Because of the reported growth of illicit trade in barbiturates and the increase in accidental poisonings and suicides by them, the Committee on Public Health in 1915 at the request of the commissioner of health of New York City again considered the desirability of extending restrictive measures regarding their sale and distribution. The commissioner submitted to the committee a draft of proposed regulations which had been formulated in cooperation with the New York office of the Federal Bureau of Narcotics.

After studying the problem and the suggested proposals, the committee came to the conclusion that stricter measures of control over the sale and distribution of barbiturates were warranted. The suggested extension of control, however, was not to operate to interfere with the freedom of physicians in their practice; rather, it was aimed to guard against misuse of barbiturates by the dispenser and the user.

The committee recommended the following specific regulations:

1. Prescriptions should be refillable when so indicated by the issuing physician; but such prescriptions should indicate a minimum interval between renewals and the total number of renewals. No prescription containing a barbiturate should be refilled after 6 months from the date of issuance.

2. Pharmacists should not reveal the content or furnish copies of prescriptions to patients.

3. Prescriptions should carry suitable information about the identity of the patient and the prescriber.

4. In an emergency a physician should be allowed to transmit to a pharmacist by telephone a prescription for not more than six average doses of barbiturate drugs provided a written prescription is supplied to the dispensing pharmacist within 72 hours. Should the pharmacist fail to receive such a written confirmation, he should notify the health department of the omission.

5. Proper records of dispensed barbiturates should be kept by physicians, dentists, and veterinarians.

6. Manufacturers, wholesalers, and jobbers should maintain suitable records of sales and distribution, and inventories of stocks.

7. Pharmacists should keep records of bills of purchase of barbiturates and copies of prescriptions on which such drugs were dispensed, including notation of amounts dispensed upon refilling.

8. Barbiturates should not be supplied to any person except on prescription or in the course of legal sale within the drug trade.

All of these recommendations in either their original or a slightly varied form were incorporated into the Sanitary Code by the end of 1917. They are presently in force.

Legislation

New York City

Prior to October 11, 1922, the Sanitary Code contained no specific provision concerning the sale of barbiturates. They were regulated by the provisions applicable to all other drugs. These regulations included:

1. Registration with the New York City Department of Health of non-prescriptive proprietary and patent medicines;

2. Provisions against misbranding, imitation, and substitution; against false and misleading statements; and against failure to disclose alcohol, narcotics, chloroform, chloral hydrate, and acetanilid;

3. Prohibition against dispensing a prescription, decoction, and medication under false or misleading name, direction, or pretense.

In 1922 the board of health adopted section 126 of the Sanitary Code which was entitled "Veronal, etc. sale regulated." This section forbade the sale at retail, except upon written prescription, of veronal, veronal sodium, luminal, and luminal sodium, together with sulphonal, tuinal, and tetranol. Additionally, these substances were designated by chemical name, and provision was made that the section apply to these drugs by whatever name called or known.

In 1940 the Sanitary Code was amended by section 116 on prohibition of manufacture and sale of

adulterated and misbranded drugs which incorporated the provisions of section 502 of the Federal Food, Drug and Cosmetic Act of 1938. This section applied to all drugs.

In the same year the Sanitary Code was further amended by section 118 which regulated more fully the sale of barbiturates in New York City. Barbiturates were included among the drugs which could not be dispensed without a written prescription, and this prescription could not be refilled if it bore an indication to that effect.

The 1945 recommendations of the Committee on Public Health were for the most part adopted by the board of health in 1947 as amendments section 118 b, c, d, and e to the Sanitary Code. Differences from the recommendations were: The life of the original prescription was reduced to 3 months. The recommendation requiring physicians to keep records of barbiturates dispensed was not adopted. Instead, labeling of the container by the physician dispensing barbiturates was specified. The provision allowing for filling of a telephone prescription for barbiturates did not appear in the amendments of 1947 but was adopted in 1948.

New York State

There was no specific legislation on barbiturates or other hypnotic or somnifacient drugs prior to 1939. In that year the Education Law was amended by addition of section 1360a entitled "Hypnotic and Somnifacient Drugs" which by definition included barbiturates. The basic requirement was a written prescription. Later in 1939, article 51 regulating the practice of pharmacy was completely revised to incorporate the provisions of the Federal Food, Drug and Cosmetic Act of 1938 with respect to drugs and cosmetics. During this revision section 1360a was repealed. No specific legislation on barbiturates was again introduced into the Education Law until 1945.

In 1945 a new section 1360a, entitled "Hypnotic and Somnifacient Drugs" was introduced into the Education Law. By definition this section again included barbiturates

of enforcement of existing State and city laws and the possibilities for the future might well be explored before turning the responsibility too quickly over to a Federal bureau.

It is the opinion of the committee that the model law for States to control barbiturates, which is patterned after its recommendations of 1945, is a highly effective legislative measure containing adequately restrictive provisions. The fault lies not in the terms of this law; indeed, it is much more restrictive and in its approach is capable of exerting much more control than are the existing Federal statutes.

Rather, the present inadequacies in controlling barbiturates are of another kind. They are four in number: First, the model law has not been adopted by all; indeed, not by a majority of the States. This is not just a matter of gross negligence or apathy. It takes time to achieve legislative remedies for social problems. But before judging the adequacy of the model law and the capability of the States to control barbiturates through it, it would seem reasonable that the law be on the books. How can effective control be expected when only 13 States have adopted the measure? How can New York City enforce its model regulations to greatest effect, assuming that it had sufficient personnel, when the rest of New York State and some of the adjoining States are exempt? In view of the demonstrated magnitude of barbiturate poisoning in New York City, the blocking of these loopholes is important. Because of the apparent concentration of the barbiturate problem in urban areas, large cities with home rule in the various States should also have laws patterned after the model act.

Second, in those States which have accepted the model law, it has been so recently adopted that its enforcement has in all probability not reached the level that might be hoped for. But time is not the only reason. Even in New York City with its highly restrictive regulations in effect since 1947, it would require considerable temerity to argue that enforcement has been exemplary. Nor should the health department be

criticized or censured. To examine properly the records of manufacturers, wholesalers, jobbers, and pharmacists requires an adequate staff of inspectors. For this the department has never had the necessary number of personnel. It has only 20 pharmacy inspectors, burdened with many other duties, to patrol 4,000 retail pharmacies and 500 jobbers, wholesalers, and packagers. It is absurd to demand more stringent laws when there is so little provision for enforcement of sufficiently strong existing measures in the Sanitary Code of New York City. More laws will not compensate for an insufficient number of inspectors.

Nor would a vast force be required. A reasonable number of inspectors engaged full time and regularly in auditing the records of pharmacies, wholesalers, and jobbers might soon instill honesty among all transactors, particularly if the element of surprise was utilized. By much the same system bank examiners have exercised a salutary influence. The problem of barbiturate poisoning in New York City has been shown to be proportionately much greater than it is in the Nation. Therefore, if the situation in New York City were improved, it would go far toward reducing the national incidence of barbiturate poisoning.

It is believed that the misuse of barbiturates is concentrated in urban areas, particularly large cities; accordingly, it follows that enforcement efforts should be concentrated there. For that a Federal Bureau is not needed.

Third, ignorance and a casual attitude have been the prevailing atmosphere surrounding barbiturates. The public has been unaware that this valuable family of hypnotics, like almost all other medication, is not without its dangers when misused. Those who know the risk of misuse, the physician and the pharmacist, have apparently not adequately informed or sufficiently impressed the patients about it.

Even after studying the figures on prevalence of use and misuse of barbiturates, the source of supply, and the legislative controls, the

committee is convinced that it has not yet come to the core of the situation. Why is there widespread use and misuse of barbiturate-containing sedatives and sleeping pills? There must be a reason. That widespread practice must be symptomatic of an underlying condition. The committee can only come to the conclusion that there exists all too much unrest, anxiety, and tension in the public.

Under these circumstances, such a radical step as prohibiting the use of the therapeutically valuable barbiturates on the grounds that it would remove a means of self-destruction would not be a sensible action or a sure corrective. With equal reason it might be argued that all high bridges and buildings should be razed, and all gas lines should be disconnected. True, it is an imperative duty to throw every reasonable safeguard around the use of barbiturates. Nevertheless, that is not a true remedy which will bring effective and permanent relief. At best it is treating the symptoms of a disease, not its cause. Now perforce it is the main recourse.

But there must also be a more fundamental approach to the solution. What is needed is a means of preventing the prevalent unrest and anxiety. For that it is necessary to have knowledge about the causes of the emotional manifestations that so abound in society. Furthermore, effective prevention of suicide can come only through an understanding of the factors that bring about a morbid state that leads to a desire for self-destruction. Knowledge on these points can only come through research. Until recently the amount expended for research on mental and emotional disorders was so infinitesimally minute as to be insignificant. Even now the manpower and funds for investigations in this area are so limited in comparison with the transcendent importance of the subject as to make the need a clarion challenge.

In sum, the committee concludes that available model legislation is adequately restrictive, but it has not been widely enough adopted; where it has been put into effect, it has not been enforced. Moreover, such

administer such a drug, shall be dispensed only:

(i) upon a written prescription, or

(ii) upon an oral prescription reduced promptly to writing and filed by the pharmacist, or

(iii) by refilling any written or oral prescription if the refilling is authorized by the prescriber either in the original prescription or by oral order which is reduced promptly to writing and filed by the pharmacist.

A drug dispensed contrary to above provisions shall be deemed misbranded.

2. Any drug dispensed by filling or refilling a written or oral prescription of a practitioner licensed by law to administer such drug shall be exempt from misbranding as specified in section 502, except as to false and misleading labeling, imitation of another drug, substitution, and packaging requirements, if the drug bears a label containing the name and address of the dispenser, the serial number and date of the prescription or of its filling, the name of the prescriber, the name of the patient, the directions for use, and any cautionary statements contained in the prescription.

3. The administrator may by regulation exempt habit forming drugs and new drugs from prescription requirements, when these are not necessary for the protection of public health.

4. A drug which is subject to the prescription requirement shall be deemed to be misbranded if at any time prior to dispensing its label fails to bear the statement: "Caution: Federal law prohibits dispensing without prescription." A drug not subject to prescription shall be deemed to be misbranded if at any time prior to dispensing its label bears the caution statement.

The United States Food and Drug Administration now uses section 503 (b) (1) in prosecuting violative sales of prescription drugs, including sales of barbiturates. It has been noted that the statement "Warning—May be habit forming" was formerly required on labels for both stock and dispensing containers of

barbiturates except when the prescription was marked "nonrefillable" or its refilling was prohibited by law. Under revised section 503 (b), as provided in the Durham-Humphrey Act, barbiturates dispensed on legal prescription do not require the statement "Warning—May be habit forming" on the label of the dispensing container.

It will be noted that the Federal law, while placing barbiturates on the prescription list, controls their manufacture and distribution by specifications of misbranding. Except for the requirement of a prescription, this approach is separate and distinct from that recommended by the Committee on Public Health. Even in the requirement for a prescription, there is no restriction on refilling, such as the minimum interval, number of refillings, and life of the prescription.

When the Durham-Humphrey Act went into effect in 1952, pharmaceutical associations and pharmacy boards in 11 States decided that the laws in their States which control the sale of drugs should be amended to bring them into conformity with the Federal statute. This action was proposed in order to eliminate the confusion to which druggists were subjected in operating under two conflicting statutes. The laws of these States were in conflict with the Federal Durham-Humphrey Act on one or both of two points: prohibition against refilling of barbiturate prescriptions, and against filling telephoned prescriptions, both of which are permitted under the Durham-Humphrey Act.

Whenever State and Federal laws conflict, the stricter law prevails. Unaware of this, some pharmacists have thought that because the Federal law permits the refilling of barbiturate prescriptions and the filling of telephoned barbiturate prescriptions, such practices are proper even though the State law bans them. Harmonizing of the laws would end this confusion. In 20 States no amendment was needed to bring their laws into conformity with the Durham-Humphrey Act. Furthermore, the model State law on barbi-

turates does not conflict with Federal regulations.

Discussion and Conclusions

It is clear that the incidence of both fatal and nonfatal barbiturate poisoning is of such a magnitude that it constitutes a problem in public health. Because it includes poisonings both under accidental circumstances and from suicidal attempt, any plan for reduction must take cognizance of these two separate aspects. It is further evident that the rate of incidence is very much higher in New York City than in the United States.

As a solution to the barbiturate problem there has been a loud demand for Federal supervision, variously expressed as stiffer Federal laws, tighter Federal control over distribution, Federal regulations similar to those for narcotics. But both commercially and pharmacologically, barbiturates are dissimilar to narcotics. It should be remembered that narcotics come from a foreign source and that the basis of control is a revenue measure. In contrast, the barbiturates are domestically produced and the model act now in effect in some States and proposed for all is much stricter; in fact, it could not with reason be much more strict. Certainly the Harrison Act for narcotics is not appropriate for or applicable to barbiturates. If what is wanted is more restrictive Federal legislation because of seeming legal inadequacy in some States, the model act for States should be carefully studied before clamoring for a Federal panacea.

Another form of demand for Federal regulation is that the Narcotics Bureau be given enough money and personnel to carry out a program to control the manufacture, distribution, and sale of barbiturates. To place this responsibility on a bureau that is already overburdened with the gigantic task of coping with illicit narcotic traffic would add an additional handicap that would indeed be formidable. It is asserted that the Narcotics Bureau is most inadequately supported for its present work. Here again the present status

of enforcement of existing State and city laws and the possibilities for the future might well be explored before turning the responsibility too quickly over to a Federal bureau.

It is the opinion of the committee that the model law for States to control barbiturates, which is patterned after its recommendations of 1945, is a highly effective legislative measure containing adequately restrictive provisions. The fault lies not in the terms of this law; indeed, it is much more restrictive and in its approach is capable of exerting much more control than are the existing Federal statutes.

Rather, the present inadequacies in controlling barbiturates are of another kind. They are four in number: First, the model law has not been adopted by all; indeed, not by a majority of the States. This is not just a matter of gross negligence or apathy. It takes time to achieve legislative remedies for social problems. But before judging the adequacy of the model law and the capability of the States to control barbiturates through it, it would seem reasonable that the law be on the books. How can effective control be expected when only 13 States have adopted the measure? How can New York City enforce its model regulations to greatest effect, assuming that it had sufficient personnel, when the rest of New York State, and some of the adjoining States are exempt? In view of the demonstrated magnitude of barbiturate poisoning in New York City, the blocking of these loopholes is important. Because of the apparent concentration of the barbiturate problem in urban areas, large cities with home rule in the various States should also have laws patterned after the model act.

Second, in those States which have accepted the model law, it has been so recently adopted that its enforcement has in all probability not reached the level that might be hoped for. But time is not the only reason. Even in New York City with its highly restrictive regulations in effect since 1947, it would require considerable temerity to argue that enforcement has been exemplary. Nor should the health department be

criticized or censured. To examine properly the records of manufacturers, wholesalers, jobbers, and pharmacists requires an adequate staff of inspectors. For this the department has never had the necessary number of personnel. It has only 20 pharmacy inspectors, burdened with many other duties, to patrol 4,000 retail pharmacies and 500 jobbers, wholesalers, and packagers. It is absurd to demand more stringent laws when there is so little provision for enforcement of sufficiently strong existing measures in the Sanitary Code of New York City. More laws will not compensate for an insufficient number of inspectors.

Nor would a vast force be required. A reasonable number of inspectors engaged full time and regularly in auditing the records of pharmacies, wholesalers, and jobbers might soon instill honesty among all transactors, particularly if the element of surprise was utilized. By much the same system bank examiners have exercised a salutary influence. The problem of barbiturate poisoning in New York City has been shown to be proportionately much greater than it is in the Nation. Therefore, if the situation in New York City were improved, it would go far toward reducing the national incidence of barbiturate poisoning.

It is believed that the misuse of barbiturates is concentrated in urban areas, particularly large cities; accordingly, it follows that enforcement efforts should be concentrated there. For that a Federal Bureau is not needed.

Third, ignorance and a casual attitude have been the prevailing atmosphere surrounding barbiturates. The public has been unaware that this valuable family of hypnotics, like almost all other medication, is not without its dangers when misused. Those who know the risk of misuse, the physician and the pharmacist, have apparently not adequately informed or sufficiently impressed the patients about it.

Even after studying the figures on prevalence of use and misuse of barbiturates, the source of supply, and the legislative controls, the

committee is convinced that it has not yet come to the core of the situation. Why is there widespread use and misuse of barbiturate-containing sedatives and sleeping pills? There must be a reason. That widespread practice must be symptomatic of an underlying condition. The committee can only come to the conclusion that there exists all too much unrest, anxiety, and tension in the public.

Under these circumstances, such a radical step as prohibiting the use of the therapeutically valuable barbiturates on the grounds that it would remove a means of self-destruction would not be a sensible action or a sure corrective. With equal reason it might be argued that all high bridges and buildings should be razed, and all gas lines should be disconnected. True, it is an imperative duty to throw every reasonable safeguard around the use of barbiturates. Nevertheless, that is not a true remedy which will bring effective and permanent relief. At best it is treating the symptoms of a disease, not its cause. Now perforce it is the main recourse.

But there must also be a more fundamental approach to the solution. What is needed is a means of preventing the prevalent unrest and anxiety. For that it is necessary to have knowledge about the causes of the emotional manifestations that so abound in society. Furthermore, effective prevention of suicide can come only through an understanding of the factors that bring about a morbid state that leads to a desire for self-destruction. Knowledge on these points can only come through research. Until recently the amount expended for research on mental and emotional disorders was so infinitesimally minute as to be insignificant. Even now the manpower and funds for investigations in this area are so limited in comparison with the transcendent importance of the subject as to make the need a clarion challenge.

In sum, the committee concludes that available model legislation is adequately restrictive, but it has not been widely enough adopted; where it has been put into effect, it has not been enforced. Moreover, such

widespread usage of barbiturates can only indicate extensive unrest, anxiety, and tension in the people. The methods to prevent this situation are still unknown. Finally, the public's knowledge and the general attitude about barbiturates do not now appear to be conducive to a more temperate and reasonable use of barbiturates.

Recommendations

As rational steps toward stopping the misuse of barbiturates and especially reducing the present high rate of incidence of barbiturate poisoning, the Committee on Public

Health offers the following recommendations:

1. The model law controlling the manufacture and distribution of barbiturates should be adopted by all the States. Large cities with home rule should also have laws patterned after this act.

2. A realistic effort toward enforcement of the model law when enacted is an essential step. An adequate staff of inspectors to examine records should be organized. Efforts at enforcement should be concentrated on the large cities, where the rates of incidence of barbiturate poisoning are highest.

3. An educational campaign

should be conducted by health departments, and medical and pharmaceutical societies to remind their members of their responsibility of acquainting patients with the dangers of misuse of barbiturates. At the same time there should be a campaign, using all media, to inform the public of the risks attached to the misuse of barbiturates.

4. Above all, it is highly desirable that adequate funds should be provided to support research on the causes of unrest, anxiety, and tension that are so prevalent among the population and are the basis for such great use and misuse of barbiturates.

Proprieties of Tuberculosis Management

By W. M. PECK, M.D.

THE PATTERN of tuberculosis control changes constantly. It changes in response to new information and needs, altered economy, predominant personalities and fads. Sometimes it flounders in complacency; other times it changes with almost chaotic flurry. But always guiding and determining this pattern are three components, the health department, the private physician, and the sanatorium, each performing a specialized function.

Since tuberculosis, as a contagious disease, is essentially a public health problem, the health department must occupy the position of overall responsibility and initiative. The private physician must guide the attitude of the patient and his community and plead the right of the individual. And the sanatorium, with its clinical and laboratory resources for research, must work out new methods of treatment and new concepts to support a changing and progressive program. Yet it is true that sanatorium physicians, in their more or less monastic seclusion, speak mostly to other sanatorium physicians, and public health physicians may be equally guilty of similar parochial practices. Since we are now in one of the more chaotic periods of change with aspects that are both heartening and hazardous, it is important that

these groups maintain the closest possible communication with one another so they may work together wisely and with adaptability through this unusual period of turbulence.

Up to now it has been customary to assert as a dictum that the basic philosophy of treatment has changed little and that drug therapy and surgery are only serviceable adjuncts to an established and time proved system. But now we must recognize that the basic philosophy itself is changing and that this constitutes the most radical departure in the changing pattern of control.

The traditional concept, which is now giving way, was starkly realistic and recognized the uncertainty of predrug therapy and the fact that tuberculosis was essentially a relapsing disease. It aimed at bringing the patient into tentative equilibrium with his disease and at maintaining that precarious balance by sheltered, restricted living. It was harsh treatment. When a patient entered the sanatorium there was forced on him a sudden break in the continuity of his life. Life plans were stripped from him and reconstituted along lines of minor attainment and little responsibility. The usual values were inverted: ambition became evil and laziness a virtue. There was a suggestion of other-worldliness, of Magic Mountain mystery about the treatment, a certain ecstasy which sustained the patient without realism and eventually enervated him. He was taught the doctrine of submission and introduced to the numbing despair of relapse through such slogans as "once tuberculous, always tuberculous." Some patients survived their illness to acquire success or even greatness, but many succumbed

Dr. Peck, presently serving as chest consultant for the North Carolina State Board of Health, Raleigh, was previously medical director and associate superintendent of the North Carolina Sanatorium, McCain. He is the current president of the Southern Trudeau Society.

to the trivial life of semi-invalidism. Thus the "cure" in days when there was no justifiable alternative.

But since then, in a matter of a very few years, a nearly specific group of drugs has appeared, changing the course and behavior of tuberculosis to an extent that it has little in common with the disease we knew only 10 years ago. Such fundamental aspects as its pathology, bacteriology, and perhaps even its epidemiology have been altered by drug action. The significance of these changes we have been slow to recognize and accept because of our innate distrust of the disease and its record for relapse. But now we are beginning to see that with optimal treatment recovery is nearly predictable and that the relapse rate—if we can project short-term results—has dropped almost to the point of removing tuberculosis from the category of a relapsing disease.

This is a difficult adjustment for all of us to make, but obviously we, who deal with tuberculosis, must "catch up" with this new type of disease and exploit its changes for the benefit of the patient and the control program. The period of hospitalization has already been shortened considerably and, as we gather confidence, probably can be shortened more, perhaps very much more. Patients now return to work within a few months of discharge and usually to their previous employment. The need for treatment in tuberculosis, then, no longer should be regarded as an overwhelming personal tragedy, and the period of sanatorium care, though intense and highly specialized, should be regarded merely as an episode which, in itself, does not disrupt or materially alter the continuity of one's life.

These optimistic remarks, of course, cannot apply to all who enter a sanatorium. Belated diagnosis and delayed admission still carry some patients past a point of possible return of adequate function. Some of these still die from tuberculosis; others survive as pulmonary cripples to whom one can offer only prolonged custodial care.

Treatment Regimen

Let us turn now to the treatment which has justified such a reversal of concept.

The goal of drug treatment, ideally, would be to sterilize the lesion of all tubercle bacilli with reversion of the tuberculin reaction. But under usual clinical conditions with our available drugs, this goal cannot be fully realized. Fortunately, there is a tangible alternate goal which falls just short of ideal. This is based on the faculty of drugs, especially of isoniazid, to destroy those bacilli which are in an active phase of multiplication and to depress the metabolic activities of the remaining organisms to a point of inertness, comparable, perhaps, to hibernation—a unique and definite vegetative state. Bacteriologists have shown that many of these bacilli cannot be induced to grow on culture media, whereas others will grow with difficulty only after many months of incubation or with special stimulation. In this dormant state tubercle bacilli continue to produce sufficient tuberculoproteins to maintain a positive tuberculin reaction but not enough to cause progressive disease. Rapid resolution of pneumonic disease and, frequently, cavity closure occur in consequence of this depressed state of the parasite; and we may postulate that host factors—factors which unfortunately permitted disease to develop in the first place—may have opportunity to rectify themselves.

Isoniazid is by far the best drug, and isoniazid and para-aminosalicylic acid seem to be the most satisfactory combination. Drug therapy is usually initiated by these two, and with almost predictable success. When they fail—as they do rarely under favorable circumstances and frequently under conditions of compromise—one loses much of the sureness, and treatment henceforth becomes difficult, specialized, and less certain. Then one must grope with problems of drug resistance, synergism, and toxicity in seeking successful combinations with streptomycin, cycloserine, pyrazinamide, or viomycin. Sometimes the surgeon must remove refractory areas of disease, the persistent cavity or the caseous mass, before sputum can be converted.

The achievement of the dormant state of the bacilli is the first objective, and the second objective is to maintain them in this state. Fortunately, it appears that dormancy can be maintained by the rather simple expedient of continuing drug therapy. Isoniazid by itself

appears to be adequate for this purpose, and ideal since it is pleasant to take and exceedingly low in toxicity and cost. Probably, continued dormancy can be further assured by the prophylactic removal of those areas prone to reactivation such as residual cavities or areas of unresolved disease which may be relatively inaccessible to the blood stream and hence to drug effect.

The tragedy of drug therapy is the ever-present possibility of interruption or compromise in the early course of treatment. The initial exposure to drugs finds the organisms particularly vulnerable. And intense, supervised drug therapy at this time will cause sputum conversion in about 80 to 90 percent of patients in the first 4 months. On the other hand, if initial therapy is inadequate or interrupted, it may have the deplorable effect of merely altering the host-parasite relationship sufficiently to produce a remarkable degree of chronicity, with active, smoldering disease persisting. It may neither improve nor worsen with further treatment.

Usually, there are about 40 such patients in the 700-bed North Carolina Sanatorium at McCain, N. C., many of whom are in its prison division. For the most part they are poor, defeated creatures with long histories of repeated "short bursts" of drug therapy. Characteristically, their shopworn lesions have practically ceased to respond to drugs, even to new ones, such as cycloserine, yet under flagrant abuse they seldom get worse. Prisoners escape and run for hours or days through the swamps. They go on the bum or work at heavy construction for months before being apprehended and returned, still hale and hearty, but with sputum that is unalterably positive. This kind of disease is the stigma of erratic drug therapy and may be produced in the well-meaning, law-abiding citizen as well as the criminal. There is a heavy responsibility on all of us lest, inadvertently by compromise or misdirection, we encourage another to join this forlorn and hopeless crowd. One must never forget that the period of early treatment is a critical one, and the difference between adequate treatment and almost adequate treatment may be relatively slight.

Assurance of proper treatment during this

early crucial period can be given best if the patient is admitted to a sanatorium. Once the organisms presumably become dormant, when the sputum becomes negative and resolution is well under way and any needed surgery is accomplished, the situation alters and much greater latitude is possible. This permits earlier discharge home and earlier return to work under the continued protection of isoniazid for a prolonged period of time, possibly for 1 or 2 years or longer; and this can be done with a degree of safety that is foreign to all earlier experience.

The Home Care Question

This treatment represents the ideal way for handling the tuberculous patient, and one cannot depart far from the ideal without some jeopardy. The question of home care, however, comes up and must be answered. The possibility of treatment at home is appealing to the patient and his relatives and has enough validity even to command critical medical attention. An argument for a home care program might be presented as follows: Drug therapy if carried out conscientiously will cause conversion of the sputum in 80 to 90 percent of initial treatment cases, and it will do this in spite of great latitude in such ancillary matters as bed rest, good nutrition, and psychotherapy. Accordingly, proponents of a program which relies primarily on home care would provide the following:

1. A system of supervision designed to insure uninterrupted drug therapy.
2. Medical supervision which would (a) endeavor to admit to the program only those patients who might be expected to have rapid sputum conversion, (b) remain alert to the development of complications or possibility of treatment failure, and (c) recognize indications for surgery.

These proponents of home care recognize that such a program is not cheap, particularly since the majority of tuberculosis patients require welfare assistance whether in or out of a sanatorium. They recognize that a considerable staff is required, including medical and nursing staff and social workers. Central clinic, roentgenographic, and laboratory facilities must be readily available. Arrangements must be made

for nurses or social workers, or both, to visit the home at monthly intervals. Lansdown and Jones estimated the cost of treating a New York City welfare patient in his home at approximately \$6 a day whereas the cost for a similar patient in a local sanatorium was approximately \$13 a day. This as well as other estimates would indicate that a home care program is about one-third to one-half as expensive as sanatorium care. Thus, the apparent cheapness of a home care program is largely illusory and is dependent on spreading the cost through a number of departments such as welfare, public health, and social service.

Opponents of a home care program point out that most of the tuberculosis patients come from underprivileged, underendowed groups who cannot assume the responsibility for their care under such a sketchy framework of supervision and that serious lapses of drug therapy will occur. Neither do they believe that bed rest, nutrition, and emotional factors are of so little consequence that they can be left to chance, especially in the determination of long-term results as opposed to short-term sputum conversion rates. They doubt that, without ready access to special facilities, sufficient sputum, gastric, or roentgenographic studies would be made for proper evaluation or that the patient could be readily persuaded to accept surgery at an optimum time. They point out, wisely, that enthusiasm for cheaper care in the home must not blind one to the communicability of tuberculosis or to risk of creating false and disastrous attitudes of nonchalance toward public health aspects of the disease.

The Reasonable Attitude

Until further data are presented a conservative and reasonable attitude in this controversy might be:

1. Where sanatorium facilities exist, reliance should be based primarily on sanatorium treatment, with home care restricted to the convalescent period and to patients temperamentally unsuited to hospitalization.

2. Where sanatorium beds are insufficient and health department personnel and facilities are sufficient to increase activities substantially, a home care program should be developed. This

program should be designed with close coordination existing between the sanatorium and home phases of treatment. Under these circumstances most patients would start treatment within the sanatorium for the initial evaluation and indoctrination and for the establishment of a suitable and tolerated drug regimen. After several weeks or months, depending on the demand for beds, the patient might be transferred (not discharged) to the home care program, but he might return to the sanatorium at later dates for periods of reevaluation or for surgical procedures. This is not an ideal program, particularly for patients who must return to forlorn and crowded homes. But it may be justified by circumstances, and it has been reasonably successful as practiced by Lansdown and Jones in New York City, Lichtenstein in Chicago, and others, especially in urban areas where excessive dispersion of the population is not a factor.

The methods of tuberculosis control, then, are by no means immutable since modern drug therapy permits increased flexibility when fundamental principles of administration are respected and accomplished with certainty. The components of a treatment program—the sanatorium, the clinic, the home—may be used with varying emphasis, depending on community resources. Extensive reliance on sanatorium facilities presents the fewest problems and the further one departs from this convention the greater becomes the responsibility, concern, and financial need of the health departments. Programs relying heavily on clinic and home treatment are indeed possible and even justified by circumstances, but they should be undertaken only after sober evaluation of resources and as a major interest. Even so, under carefully controlled conditions, there is justification for further cautious exploration in this direction. There is danger, however, that home care programs may be undertaken somewhat hastily because of a mistaken assumption of great economy, because of popular clamor, or because of insouciance. And there is danger that home care and sanatorium care may be pitted against one another in wasteful competition. Such attitudes must not be tolerated. Instead one must seek constantly to command optimum use of all these community resources.

This concept presents us with opportunity

for building a program on a much broader and more secure base, an opportunity for freshening and strengthening a campaign which has lost much of its momentum, an opportunity for

reawakening those forces which once distinguished tuberculosis control measures as an actual crusade in which the entire community eagerly joined.

Federal Water Pollution Control Act of 1956

Federal grants to assist municipalities in the construction of necessary sewage treatment works as a pollution control and water conservation measure, to be administered by the Public Health Service, are authorized in the Federal Water Pollution Control Act of 1956 (P. L. 660, 84th Cong.).

The act also authorizes up to \$3 million a year for a 5-year program of grants to States and to interstate water pollution control agencies to assist them in developing their own water pollution control operations. A revised Federal enforcement procedure for control of interstate water pollution and greater Federal support for research are among other important provisions of the act.

Under the revised enforcement procedure, Federal court action to abate interstate water pollution may be taken by the Government at the request either of the State in which the pollution originates or of the State affected by the pollution. Under the 1948 act, the consent of the upstream State was required.

The 1956 act also authorizes an intensified program of research, technical assistance, and training. Research work at the Public Health Service's Robert A. Taft Sanitary Engineering Center at Cincinnati, Ohio, will be augmented by means of research grants, contracts, and fellowships.

The statute authorizes Federal grants of \$50 million a year (up to an aggregate of \$500 million) for the

construction of municipal sewage treatment works.

Construction Grants

The supplemental appropriation for the current fiscal year includes \$50 million for construction grants which are to be allotted on the basis of population and per capita income. Under the act, individual grants are limited to 30 percent of the estimated reasonable cost of the project or \$250,000, whichever is less. The act requires that at least 50 percent of the grant funds be used to assist in construction of treatment works serving communities of 125,000 or less.

A project must meet six basic requirements to be eligible for a Federal construction grant: (a) The project must be approved by the home State's water pollution control agency; (b) it must conform to a State water pollution control plan submitted pursuant to the act; (c) it must be included in a comprehensive water pollution control program of the Public Health Service; (d) the applicant must agree to pay the remaining construction costs; (e) the applicant must make provision for insuring proper and efficient operation and maintenance of the project after construction; and (f) the home State's water pollution control agency must certify that the project is entitled to priority over other eligible projects on the basis of financial as well as water pollution control needs.

Application Procedures

Preliminary information on the operation of the new act continuing Federal-State cooperation in controlling water pollution has been released by Surgeon General Burney. Placed in charge of the initial operation of the program is Curtiss M. Everts, chief sanitary engineer of the Oregon State Board of Health.

Application forms and related materials will be available to municipal officials and others concerned from State and interstate water pollution control agencies, from the regional offices of the Department of Health, Education, and Welfare, and from the Public Health Service in Washington, D. C.

After completing the form, the applicant will submit it to his State water pollution control agency for approval and request notification on whether the project meets the requirements of the State water pollution control plan.

The Public Health Service will determine which projects satisfy the criteria for propriety of Federal aid and other requirements of the act.

More detailed procedural information will be available with the grant application forms.

Arrangements for the practical application of other provisions of the act are being prepared. The supplemental appropriation also included \$2 million for program grants to States and interstate water pollution control agencies and \$1 million for administration of the various provisions of the act.

for nurses or social workers, or both, to visit the home at monthly intervals. Lansdown and Jones estimated the cost of treating a New York City welfare patient in his home at approximately \$6 a day whereas the cost for a similar patient in a local sanatorium was approximately \$13 a day. The methods of tuberculosis control, then, are by no means immutable since modern drug therapy permits increased flexibility when fundamental principles of administration are respected and accomplished with certainty. The components of a treatment program—the sanatorium, the clinic, the home—may be used with varying emphasis, depending on community resources. Extensive reliance on sanatorium facilities presents the fewest problems and the further one departs from this convention the greater becomes the responsibility, concern, and financial need of the health departments. Programs relying heavily on clinic and home treatment are indeed possible and even justified by circumstances, but they should be undertaken only after sober evaluation of resources and as a major interest. Even so, under carefully controlled conditions, there is justification for further cautious exploration in this direction. There is danger, however, that home care programs may be undertaken somewhat hastily because of a mistaken assumption of great economy, because of popular clamor, or because of insouciance. And there is danger that home care and sanatorium care may be pitted against one another in wasteful competition. Such attitudes must not be tolerated. Instead one must seek constantly to command optimum use of all these community resources.

This concept presents us with opportunity

volumes to more than 100,000, and the *Index-Catalogue*, which Dr. William Welch, of Johns Hopkins University, once called the most important contribution the United States had made to medicine, had come into being. Dr. Billings had, in fact, accumulated for the library the world's greatest collection of medical literature.

Likewise, but as a private enterprise, the *Index-Medicus* owes its origin to Dr. Billings' vision. Begun in 1880, the index was united in 1927 with the *Quarterly Cumulative Index* to form the *Quarterly Cumulative Index Medicus*. It is now published by the American Medical Association.

After the First World War the library was renamed the Army Medical Library, and again, in 1952, its name was changed to the Armed Forces Medical Library.

Today the library possesses half a million bound volumes and more than a million titles in medicine, public health, dentistry, and allied sciences in all languages and of all times. More than 10,000 serials are acquired yearly by purchase, gift, or exchange, including about 4,500 journals.

Not only does the library have more than 500 incunabula and many thousands of rare books of later dates, but its collection of theses, also started by Dr. Billings, is unsurpassed. The long runs of periodicals give it a character possessed by few other scientific libraries. Its collection of portraits of medical men and pictures of hospitals is growing daily. Its section of American and foreign government and statistical documents is probably unique.

In addition to acquiring medical literature on a worldwide basis, the library organizes its acquisitions by appropriate bibliographical listing, makes them available to users through interlibrary loans and photographic copies, and provides reference and research assistance. From its beginning, in addition to serving military users, the library has been used extensively by the civilian medical profession.

The library publishes the most extensive periodical index in existence today, the *Current List of Medical Literature*. The current list appears monthly, and its subject and author indexes are cumulated semiannually. It has a circulation of 4,500 copies.

A published *Catalog* appears annually and is cumulated quinquennially. It lists by author and subject the books added to the collections.

The *Bibliography of Medical Reviews*, an experiment undertaken in 1955, contains citations for the review literature of medicine which appeared during that year. A second edition is in preparation covering the review literature of 1956.

A series of occasional long bibliographies on topics of current interest has been published since 1950. The most recent example is a study on cancer chemotherapeutic agents, prepared in cooperation with the National Cancer Institute, Public Health Service, now in press as a supplement to *Cancer Research*.

About 15,000 interlibrary loans and about 100,000 photoduplicates are made yearly as an extension of the library's services to other libraries, institutions, and to those users who cannot consult the collections in person. Each month the reference staff answers about 1,000 questions received by mail and over the telephone. The staff numbers more than 200 persons, including several physicians, chemists, and other specialists in the biological sciences. In response to the nature of the literature acquired, the staff embraces an unusually wide range of language competency.

The library has long since outgrown the old red brick building, next to the Smithsonian Institution, into which it moved in 1887. Since 1942, the oldest part of the collection, some 40,000 volumes of its most valuable materials, have been shelved in Cleveland, 400 miles distant from the government agencies which most use the library's facilities. Additional stacks recently built into the old building will provide for the library's needs only for about 2 more years. More than 50 years ago Dr. Billings was saying that "the library is in urgent need of shelving for its additions, some of which are being stored on window sills or on the floor."

In giving a new status and name to the National Library of Medicine, Congress has authorized the construction of a new building on a site to be selected by the Surgeon General at the direction of the Board of Regents. Funds for architect's plans have been appropriated.

The National Library of Medicine

THE Armed Forces Medical Library has been transferred to the Public Health Service and is now operating as the National Library of Medicine.

Although as early as 1876 the library was called the National Medical Library on the title page of one of its publications, the designation did not become official, and the national character of the library was not legally recognized until 80 years later. On August 3, 1956, President Eisenhower signed the act (Public Law 941) of the 84th Congress establishing the National Library of Medicine "to assist the advancement of medical and related sciences and to aid the dissemination and exchange of scientific and other information important to the progress of medicine and to public health."

The transfer, observed with ceremony on October 1, 1956, involves the largest collection of medical literature in the Western Hemisphere and one of the largest research libraries in any special subject field. Colonel Frank B. Rogers will continue as director of this institution.

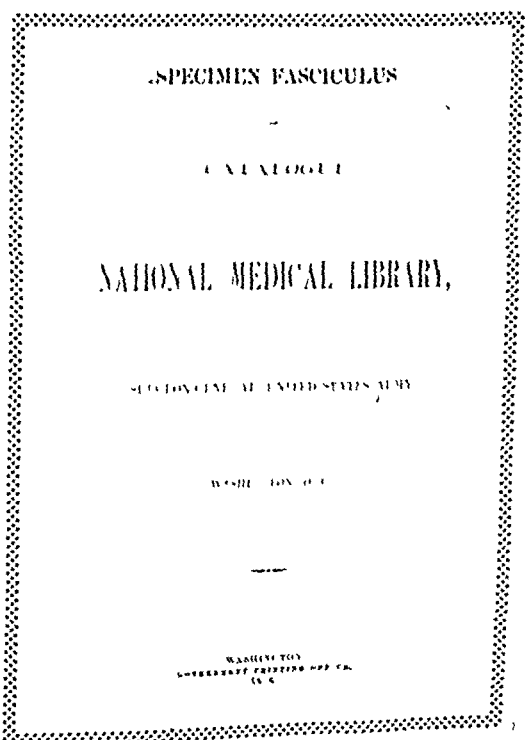

The act places the library under the Surgeon General of the Public Health Service. On matters of policy, scope of collections and services, and the rules under which the facilities of the library are to be made available to users, the Surgeon General will be advised by a 17-member board of regents, 7 of whom will serve ex officio. In addition to the Surgeon General, these are the Surgeons General of the Army, the Navy, and the Air Force, the Chief Medical Director of the Veterans Administration, the Assistant Director for Biological and Medical Sciences of the National Science Foundation, and the Librarian of Congress. The 10 other regents will be appointed by the President from the fields of medicine, library science, or public affairs.

Now entering its 121st year, the National Library of Medicine was founded as the Library of the Surgeon-General's Office (United States Army) in 1836, when Andrew Jackson was

finishing his second term as President. It was a time when the heroic therapeutic measures of men such as Bard and Rush were beginning to fall into disrepute. It was the time when Beaumont in the United States and Hodgkins, Addison, and Bright in England were ushering in a new era of medicine.

In those early years the library was little more than a few shelves of books. The manuscript catalog of 1840 listed only 228 volumes. The library grew slowly until after the Civil War. Then two things happened: It received a large sum of money remaining from wartime hospital accounts, and Dr. John Shaw Billings was named librarian. With tireless energy and determination, he began to amass books, reports, transactions, and periodicals from all over the world.

By the end of his 30-year administration, the library's collections had increased from 2,000

age

The following pages carry material selected for its relation to a single theme: the responsibility of the health professions for the aged population, identifiable less by their years than by their needs. Comments on public health programs for the aging are offered in the leading statement by Surgeon General Leroy E. Burney.

Trends in gerontology and several of its aspects are covered in five papers from the research seminar held at the University of Michigan Conference on Aging at Ann Arbor, July 1956. Reports of other sessions at that conference follow.

Certain recommendations of the first Federal-State Conference on Aging, held in Washington, D. C., in June 1956, are published for their particular value to public health agencies.

Included in the section are two privately contributed reports. Dr. Pemberton and Dr. Macleod assay the health status of a group of men over 40 in a rural area, and Mrs. Belloc reports on eyesight in the aged.

Selected Papers of Joseph W. Mountin

By E. G. McGAVRAN, M.D., M.P.H.

*Selected papers of Joseph W. Mountin, M.D.
[Published by] Joseph W. Mountin Memorial
Committee. New York, American Public Health
Association, 356 pp. Price \$5.*

. . .

THE PUBLICATION of "Selected Papers of Joseph W. Mountin" by the Memorial Committee is perhaps the finest memorial and tribute possible to a great public health man.

In this historical document, students and scholars of public health can see clearly the phenomenal growth of public health in this century.

Beautifully planned, organized, and edited, the book holds great value for the careful reader or the skimmer. Each chapter, and frequently each paper, is accompanied by editorial comment and quotations that highlight that particular subject matter. Key words, ideas, and concepts throughout the multiplicity of subject matter stand out and give emphasis through repetition to the character of the author. These are things Joseph Mountin felt to be important in public health. These are the things that made him a public health statesman, ahead of his time but with feet solidly upon the ground.

Each reader may pick for himself the threads that run consistently throughout the fabric of these papers. For example, there is the thread of change: "divine discontent with the traditional, with past or present performance and concepts . . . public health as a dynamic moving force in a changing social order, an emerging science . . . changing concepts . . . changing patterns . . . adaptation to meet the changing needs . . . adjustment to meet new situations."

It is popular today to include gerontology in our list of public health responsibilities, but Dr. Mountin set down forcefully years ago

what our responsibility for how we may go about meeting it. He warns us of the danger of conforming to the "orthodox" principles of public health—"How free we seem; how free we are"—but advises that we study seriously the health needs of our community so that we may promote and conserve its health more efficiently. This is the spirit of scientific inquiry, the spirit of scientific freedom, that is the mark of the best minds in any profession.

A prominent thread is Dr. Mountin's concern for the future of public health. Glaring through the titles of his papers: "Planning for Public Health," "The Evolving Pattern of Tomorrow's Health," "The Future of Public Health Nursing," "Organizing for the Newer Public Health Programs." It is not enough to consolidate our gains, to live on past accomplishments, to hold the line. We must be pushing back the frontiers of knowledge in community health, our distinctive area of competence. The "pioneering spirit" is what is needed, and that spirit requires courage—courage, conviction, and dedication of a high order—for pioneering in health today is more adventurous than was the land pioneering of our forefathers, for we live in the wealthiest and therefore the most conservative nation upon the face of the earth. Dr. Mountin's papers demonstrate this courage as his life demonstrated its dangers. Note the weight he constantly places upon trends, the scientific prognosis of what the future holds for us in health status, health needs, problems, and opportunities.

Another thread is evaluation. Dr. Mountin does not discard programs and activities because they are traditional, but he does emphasize evaluation—constant critical analysis of any program, old or new, to determine its effectiveness, and exploration and research in administrative methods to see if there is a better way to meet community needs. He is not satisfied with scientific diagnosis, prognosis, prescription, or treatment of community health problems. He wants constant scientific supervision and followup. This is the spirit of a great public health physician whose concern is for his patient, the community, and not merely the science of his profession of public health.

in their homes. It has been done, here and there, by the Allegheny County Institutional District in Pennsylvania, at the Goldwater Memorial Hospital in New York City, and at the District General Hospital in Washington, D. C.

The health maintenance clinic is no longer a pipe dream. This idea for the improvement of adult health is being applied in the University of Miami Medical School and, limited to recipients of old age assistance, by the Santa Cruz County Health Department in California. In New York City and Worcester, Mass., medical societies, health departments, and voluntary agencies are experimenting with "well-oldster conferences." They say the "well oldsters" don't object to the obvious "well baby" comparison, quite the reverse. Equally sporadic is the development of adequate home care programs; yet, 90 percent of the disabled 65-and-over group is at home. Almost untouched is the quality of care in nursing homes; yet, many State health departments are responsible for the licensing of such facilities. So, also, is the idea of cooperative services to the chronically ill and aged in which many community agencies, voluntary and official, participate.

Are we, the appointed guardians of public health, going to remain content with piecemeal services for the increasing millions of older people? We in the Public Health Service are going to give this problem top priority in our program planning. We have already taken some of the steps. We shall take others, assign more personnel, cooperate with the States to the fullest extent of our available resources.

I wish to add one caution. Public health

practitioners and private practitioners are not miracle workers. I fervently agree that some of the improvements we could make tomorrow, with relatively simple means, might seem miraculous in their beneficial effects on the lives of many older people. But the social, economic, physical, and emotional problems of growing old in our society are complex and difficult of solution. No efforts on the part of public health and medicine to improve the health of the aged can be fully successful unless society is willing to make parallel efforts in related fields. We cannot be all things to all men. So let our planning for health of the aged be predicated upon the following assumptions:

- That continued efforts will be made to improve financial security of our older citizens.

- That parallel efforts will be made to remove arbitrary restrictions on the employment of individuals because of chronological age.

- That there will be no diminution in the Nation's current medical research effort, leading to more effective health care and control of chronic disease.

- That existing health and rehabilitation programs be sustained and progressively expanded so that maternal and child health services and other preventive and restorative programs may assure oncoming generations a foundation of better health as they reach old age.

- That the concept of Federal-State cooperation and of working together with the professions and the public will continue to inform and inspire all that we do for the better health of the aged.

Programs for the Aged

By LEROY E. BURNEY, M.D.

The Surgeon General's address at the banquet for the State and Territorial Health Officers, November 8, 1956, Washington, D. C., was climaxed by the following strong appeal for programs for the aged.

. . .

IT IS IMPORTANT that the public health profession develop swiftly some mutually acceptable principles upon which to base our planning in the vital and inseparable fields of aging and chronic illness.

If we do not institute constructive action to improve the health of the aged and reduce the burden of chronic illness in more communities and States, we will have failed in our plain duty to the people we serve—and that is the whole community not merely a certain segment.

I speak bluntly for the good reason that, at national and State levels, the problem of aging has become a matter of public policy with a high priority for action. It has grown over the years until now it has come to a head, presenting all the classic signs: rubor, calor, dolor, and tumor. Unfortunately, the signs of heat and irritation are observed chiefly in public and private deliberations on how to solve the problems of aging while the aged individual and his family continue to suffer the pain and our national economy, the swelling. Our communities, States, and Nation want some practical, feasible means of treatment.

As physicians and health specialists we can expect to be called in consultation. Are we prepared to give sound advice on what should be the next steps for improvement in our own field, health of the aged?

Health is a central factor in every aspect of the older person's life. It cuts across every social, occupational, and economic line. It affects every proposal for improving the lot of older people in family life, employment, recreation, and participation in community affairs.

A few specialized programs have been initiated in the past decade which, it is true, are directly related to the health of people in the fifth and succeeding decades of life. I refer to community mental health services and tuberculosis, cardiovascular disease, and cancer control. The earlier venereal disease control program also is directly related to adult health. Even if these specialized Federal-State programs were at this moment operating at peak effectiveness in all parts of the country, they could reach only a fraction of the disabilities seriously affecting the adult population of middle and later ages.

And I should be less than candid if I did not say, here and now, that our existing specialized programs reach pitifully few of the men and women who need them most: the aged. As a candidate for that category, I have a personal sense of misgiving when I realize that the age groups which have the shortest remaining life expectancy also receive the short end in health and related services. Yet, there is so much health departments could do now if they had the resources and the vision. We simply haven't begun to apply the knowledge already available.

In terms of national health and national economy, there are incalculable savings to be made through restoration of bed-bound, institution-bound older people at least to self-care

blood vessels of the uterus may even tend to lose their calcification, which was due to arterial strain. It has been demonstrated that the mental response of a patient may be improved, that such things as memory, ability to coordinate thought, judgment, and the like, may be benefited by therapy. We can say that the biological function and physical tissue may be modified and that they parallel one another. This phase of gerontology needs much research, and much may be accomplished by proper study and evaluation.

Can and should these changes be modified? From my limited experience I feel that knowledge will lead to a definite modification of tissue and its function, which will in turn extend the health of older people. Many of the diseases found in older people are attributed to arteriosclerosis, but since the advent of pathology physicians have found that a clinical diagnosis of arteriosclerosis is not always substantiated by autopsy findings. Children died of diarrhea, which was later found to be preventable by control of the nutritional state of the infant. The trend in biological study is upward, but the ascent is very slow.

Psychology

There are so many factors that influence the psychology of the older person that it is difficult to evaluate them briefly. The need for a better adjustment of the older person to his environment, the need for economic, social, and medical security, all enter into the mental and emotional disturbance of his existence. Control of these factors leads to a healthier outlook on life, to a better understanding of the emotions, and must come through proper education of the individual and a realization on his part that aging is not something to be shunned, but something to be accepted and adjusted to. As most of our youngsters are taught, so should our oldsters be taught that they must prepare themselves for the future in order to have a pleasant corner in life at any age.

There is an increasing realization of the need to develop this thought. I can point particularly to the University of Michigan, which has taken the lead in the control of the psychological aspect of older people. This institution is

well known for studies concerning the mental health, the emotional needs, the adjustment to an industrial program, and the education of the older person. Proper thinking in the field of psychology of the aging by the leaders is well assured. Administration of this thought to those who need it is, of course, difficult. It must come with education of the masses of older people. The trend toward proper evaluation in the field of psychology is strong.

Clinical Medicine

Clinical medicine has for generations shied away from the subject of gerontology and is still doing so. Few medical schools teach any of its principles. Few of the teachers in the schools realize its importance, and consequently few teach medical students and interns the problems of aging, particularly the anticipation of disease. They sack up most diseases that occur in older people and call them arteriosclerosis and shake their heads and say: It is inevitable. There is an awakening of thought in the direction that some of the changes that occur with age may be modified and that basic underlying changes which lead to the diseases of the older person may be recognized and treated. However, the problems of geriatric medicine have not yet received proper recognition.

The trend in clinical medicine is a sort of status quo. Many clinicians still think that illness must occur with age. Since they feel that a disease must occur before treatment is started, they are unable to approach the prophylaxis of gerontology. They are unwilling to anticipate that illness may occur unless something is done to direct and control the body functions. It is important to emphasize that acute phases of chronic disease do not occur suddenly; rather they progress slowly and have their existence as a result of changes that began long before the acute phases developed. Internal medicine needs to take a page out of the book of pediatrics from the standpoint of prophylactic and anticipatory medicine.

Nevertheless, the clinical state of the older patient has been much improved. Many types of conditions that frequently lead to chronic diseases are now controllable. For instance,

Trends in Gerontology

By WILLIAM B. KOUNTZ, M.D.

WHAT IS GERONTOLOGY? We might say that it is an understanding of the process of aging, or a form of therapy, or a form of evaluation of the problem of aging. All these are true in their own way, but, actually, gerontology is a cumulative process of thinking in regard to one of the important problems of existence. Gerontology is indeed a broad word, covering many facets of our existence.

Much like medicine itself, gerontology had to create a logical place in the human mind before it could be established. Since thought develops slowly and in stages, the most critical point is usually the one considered first by the mind. Because of the need, generations ago, for attention to the health of the younger individual, the problems of the early years of life were attacked most vigorously and the science of pediatrics was established. It was only after the application of this direction of study and observation of the results that the problems of the period past midlife became critical in the mind of man. We are now at the stage where gerontological control in all its different phases and aspects looms high as one of the greatest needs of mankind.

Since gerontology is divided into different units, or disciplines, we shall consider each one separately.

Dr. Kountz is assistant professor of clinical medicine, Washington University School of Medicine, St. Louis, Mo.

Biology

Since there is definite biological change in everyone from his unicellular state to maturity, the biological problem is important not only in the period of growth and development, but also in maturity and later years. In considering the biological aspect of aging, there are a number of questions that must be asked: Is the body as it ages fixed in its principle so that the changes cannot be modified? Should we expect biological change to be comparable to the process of boiling an egg? Can such anatomical and functional changes as occur with age be modified?

These questions have been answered definitely. It has been shown that there may be a reversal in the picture of tissue, both biologically and functionally, long after the tissue has ceased its normal activity, that actually the functional capacity of the tissue may be returned to near normal and the biological appearance of the cells and tissues may again approach that of younger periods of life. Since this can be demonstrated in certain tissues, it is highly possible that other tissues may be modified in both their functional capacities and anatomical appearance.

It has been shown that the epithelium of the nose and throat may again develop cilia and that an improvement of this tissue may occur after the functional capacity of the mechanism has been greatly reduced. It has been demonstrated that the endometrium of the uterus may be returned to a state resembling its former state in anatomical appearance and even, in part, in function. With proper therapy, the

Psychological Limitations That Occur With Age

By JAMES E. BIRREN, Ph.D.

THE PURPOSE of this paper is to describe a few limitations that may occur with age and to draw some preliminary inferences about the underlying mechanisms. The scientific literature on the psychological aspects of aging is increasing. The contributions from the Cambridge Laboratory in England (1-4) and the publications of numerous investigators in this country have given us many facts to digest. Recently, reviews have appeared on special aspects of aging, such as psychomotor changes, changes in mental abilities, and changes in personality (5-7). Many summaries of the literature were presented at the Bethesda Research Conference on the Psychological Aspects of Aging (8). With this factual background in mind, it is proper that we begin to consider some of the general mechanisms which may underlie the psychological limitations of aging.

It is implicitly assumed that from considerations of basic facts and information suggestions will become apparent for the prophylaxis and alleviation of many of the limitations which occur with age. Because we use the term "limitations of aging," it should not be assumed that aging is inevitably linked with limitations. The advantages associated with advancing age, like those of growth, take care of themselves, but

limitations and defects do not. To these we must direct the knowledge of our sciences and professions if we are to increase the number of healthy, happy, informed, and independent older persons.

A Point of View

There are two psychologies to be considered in relation to limitations of aging. One is clinical and is concerned with diagnostic, therapeutic, rehabilitative, and supportive procedures. The other is directly concerned with research or experimentation on mechanisms of aging. The point of view adopted in this paper is that of research. We are seeking explanatory principles that might begin to link the now disparate facts about aging.

Generalization vs. Individual Differences

For many psychological and biological processes, about 50 percent of the variation in the data is explained by the general age trend. Thus, in many studies, the range of individual differences is about equal to the magnitude of the mean trend. Whether we emphasize the general trend in our psychological or biological data or the range of individual differences depends upon our purposes. The clinician is more often interested in the uniqueness of the individual under study than in the general characteristics he shares with other people. The biologically minded psychologist is more often concerned with an analysis of the general

Dr. Birren is chief of the Section on Aging, Laboratory of Psychology, National Institute of Mental Health, Public Health Service, Bethesda, Md.

hypertension, or high blood pressure, has been brought under control to a great extent in the past few years, a fact that will doubtless help to prevent illness in many oldsters. The understanding of dietary problems, such as the influence of fats in the control of arterial disease, and the understanding of the nutrition of the body likewise play an important part in the control of chronic disease. Surgery, with its ability to replace diseased blood vessels, leads to improved health in the older person. The early recognition and surgical treatment of cancer of the breast, the uterus, and the lung also help to extend health into the later years of life. And much could be said about the introduction of medications and techniques in specific disease, all of which lead to better health.

The trend in the clinical aspect of the control of disease in older people is definitely upward, but there is still need for earlier recognition and earlier clinical evaluation before prevention of disease can come into its own. The treatment and control of disease in older people has been much improved, and the trend to better health is a trend to a brighter outlook.

Other Aspects

The social, economic, and religious aspects of life for older persons vary a great deal from these aspects of life for young people. The social aspect is often modified by a change in

clinical health, in economic ability, and particularly in the psychological outlook of older individuals. That social needs should be recognized and social adjustment aided there can be no doubt. The trend is in this direction: for example, social security, old age pensions, and housing projects for the aged. Fraternal organizations and other groups are beginning to make moves toward meeting the needs of their retired members. In my experience the social aspect is always conditioned by psychological and clinical health. Those in poor health need social adjustment and social help; those in good health maintain their own level.

Another trend of great importance is the increasing concern among lay people with the results of gerontological research. If properly directed, their interest can speed the progress of gerontology. It will serve to create a demand on scientists and physicians to develop the knowledge necessary to assure health in the later years. This emphasizes the need for the formation of foundations to help develop further study and to establish funds for research, as well as to permit the expression of lay people in the field. This type of organization enables the layman and the scientist to become partners in gerontological research, and no more important a relationship can be established. One such organization, the Gerontological Research Foundation, has already been set up.

Director's Program on Aging

William C. Fitch, of the Bureau of Old-Age and Survivors Insurance, has been named director of the special staff on aging, a newly created post in the Department of Health, Education, and Welfare.

Mr. Fitch, who began his career in 1937 as assistant manager of the Kingston, N. Y., Social Security District Office, was assistant to the director of the Bureau of Old-Age and Survivors Insurance prior to this appointment. He was a member of the Department's Committee on Aging and consultant to two of the annual University of Michigan conferences on aging. In September 1956 he returned to the United States after serving for a year as social insurance adviser to the Government of Israel.

The special staff on aging represents an expansion of the Department's program on aging. Clark Tibbitts will continue as chairman of the Department's Committee on Aging, established in 1950.

Psychological Limitations That Occur With Age

By JAMES E. BIRREN, Ph.D.

THE PURPOSE of this paper is to describe a few limitations that may occur with age and to draw some preliminary inferences about the underlying mechanisms. The scientific literature on the psychological aspects of aging is increasing. The contributions from the Cambridge Laboratory in England (1-4) and the publications of numerous investigators in this country have given us many facts to digest. Recently, reviews have appeared on special aspects of aging, such as psychomotor changes, changes in mental abilities, and changes in personality (5-7). Many summaries of the literature were presented at the Bethesda Research Conference on the Psychological Aspects of Aging (8). With this factual background in mind, it is proper that we begin to consider some of the general mechanisms which may underlie the psychological limitations of aging.

It is implicitly assumed that from considerations of basic facts and information suggestions will become apparent for the prophylaxis and alleviation of many of the limitations which occur with age. Because we use the term "limitations of aging," it should not be assumed that aging is inevitably linked with limitations. The advantages associated with advancing age, like those of growth, take care of themselves, but

limitations and defects do not. To these we must direct the knowledge of our sciences and professions if we are to increase the number of healthy, happy, informed, and independent older persons.

A Point of View

There are two psychologies to be considered in relation to limitations of aging. One is clinical and is concerned with diagnostic, therapeutic, rehabilitative, and supportive procedures. The other is directly concerned with research or experimentation on mechanisms of aging. The point of view adopted in this paper is that of research. We are seeking explanatory principles that might begin to link the now disparate facts about aging.

Generalization vs. Individual Differences

For many psychological and biological processes, about 50 percent of the variation in the data is explained by the general age trend. Thus, in many studies, the range of individual differences is about equal to the magnitude of the mean trend. Whether we emphasize the general trend in our psychological or biological data or the range of individual differences depends upon our purposes. The clinician is more often interested in the uniqueness of the individual under study than in the general characteristics he shares with other people. The biologically minded psychologist is more often concerned with an analysis of the general

Dr. Birren is chief of the Section on Aging, Laboratory of Psychology, National Institute of Mental Health, Public Health Service, Bethesda, Md.

characteristics. Both the general trend and the range of individual differences are proper subjects for study.

An Emerging View

As individuals, we are continually concerned with an emerging point of view toward human aging, that is, the proper combination of generalizations with specific facts from personal experience. At some point the experimenter joins with the clinician and with informed people in general to give an appropriate weighting or perspective to the facts of psychological limitations in aging. But what facts should be emphasized? Should we emphasize that there appears to be a disparity between the observable anatomical changes of aging of the nervous system and the changes seen in individual behavior and personality? If this is emphasized, we encourage acceptance of or complacency about our lack of knowledge concerning the relations between psychological functions and the structures of the nervous system. It does not appear to be sound mental health to encourage the idea that successful aging is entirely a voluntary phenomenon and that all older people are capable of doing outstanding things if they would only try. The mature point of view toward human aging seems to represent a balance between optimism and realism and an avoidance both of excess voluntarism and of undue stress on the limitations of aging.

Speed in Timing in Human Behavior

Perhaps the most significant result of research on age changes in the nervous system in the past 10 years is the implication that there is a general slowing of all voluntary responses. In a previous review it was pointed out not only that the slowing of voluntary responses with age is an overt manifestation but also that there is evidence of slowing of covert responses in aging, such as speed of associations of thought (9). The change in response latency appears to be our most fruitful point of departure for exploring the nature of age changes in behavior and perhaps for the significance of the age changes in the structures of the nervous system.

In young adults individual differences in

speed seem to have only limited psychological importance. In aging, however, individual differences in speed or response latencies seem to be an important independent variable for the psychologist to consider. Recent research suggests that the time delay between stimulation and response is primarily a property of the central nervous system, whereas earlier research tended to minimize the importance of time differences that might be observed in simple and choice reaction time measurements. The slowing with age has to some extent been viewed as an arbitrary or artifactual aspect of performance of the older person. Implicit in such a view is the assumption that the slowing occurs only in the response or output mechanisms and is unrelated to the speed or the quality of events preceding the initiation of response. Were the loss of speed with age a peripheral phenomenon, it would of course be of limited psychological interest.

Simple speed tests seem to differentiate more clearly between senile psychotic individuals and control subjects than do various combinations of rather complex mental tasks. For example, a 2-minute writing test was found to differentiate senile patients and control subjects (10). In contrast, a 1½-hour psychometric test designed to measure deterioration did not yield such differentiation. Again, later studies showed that this difference was not simply a peripheral limitation on the writing speed, but that the speed of writing was correlated with the probability of the antecedent events being correct (11).

What requires the additional time in the older nervous system? Does a timelag occur in the retina or in the optic nerve? Is there an increased latency in the primary sensory projection area of the brain or in an association area? Is additional time required in programming appropriate motor responses in the motor cortex or in the spinal cord? Does the peripheral nerve or the myoneural junction require more time in its functions?

It was originally thought that older people adopted a slow tempo of response. Hence the increased latencies of voluntary responses were not viewed as a reflection of reduced capacities of the nervous system but phenomena of attitude or set. It has now been shown that at

least in one other species, the rat, a slowing of response latency occurs with age. In a recently published study of startle responses of rats of different ages, it was shown that for older rats there is an increase in response time to electric shock and to sudden noises (12). Furthermore, when attempts were made to decrease the response time of these animals by increasing the electric shock, a minimum reaction time was reached beyond which a further increase in the stimulus strength did not result in a further reduction in reaction time. At this plateau, or asymptotic level, of response, there was a residual difference between young and old animals.

An experimental attempt was also made to see to what extent the slowing with age could be related to conduction velocity of peripheral nerve in the rat. In this study the conduction velocity was measured in isolated sciatic nerve excised from more than 75 rats ranging in age from 50 to 850 days (13). Conduction velocity increased during development, but it did not change significantly after about 300 days. The results of that study taken together with results of previously reported studies indicate that changes in peripheral nerve do not appear to be important in the changes which we see in such functions as simple reaction time in later life (9, 14).

Recent and unpublished studies by Dr. Alfred Weiss of the National Institute of Mental Health and by Dr. Botwinick, also with the institute, and myself have found no evidence as yet that the age changes in the speed of human voluntary response to any large extent lie in either the receptor or in the effector processes. An earlier study by Johannes Sommer indicates that the age change in a simple spinal reflex in the human is small; it seems to be of the order of perhaps 1 millisecond compared with the 50 or more milliseconds that differentiate the voluntary responses of a young and an older person (9).

The recent work of Kumnick on pupillary responses to light indicates that under some circumstances the latency is unchanged with age. This implies that at least under some conditions the rapidity of all the events, from the stimulation of the receptors in the eye to the effecting of pupillary constriction, must be

unchanged with age. Apparently, the older pupil constricts at a normal rate in proportion to its smaller size. Since the older pupil is usually somewhat smaller, it may, however, give the illusion of a slower response. If this rather complicated reflex remains unchanged in later life, we might speculate that some of the purely sensory components are also unchanged in relation to latency of perception and the initiation of voluntary responses.

Apparently, the decrease in speed of voluntary responses with age is primarily a phenomenon of the central nervous system and conscious behavior. This provokes a dilemma because the physiological methods which might be appropriate to a study of the phenomenon are ones which are so artificial (for example, anesthetizing the organism) that they preclude studying manifestations in the conscious state. The problems lie in an experimental area wherein the relevant types of experimentation and variables are familiar to the experimental psychologist, and the inferences lie in the domain of the neurophysiologist.

A depressed person might respond slowly and yet retain a capacity to respond quickly, whereas it is extremely doubtful that the older organism maintains the capacity for rapid response. Responses of the elderly are made at some uniformly slow rate (15). This suggests that we might speak of less "temporal modulation" of voluntary responses. Implications of this concept are important in attempts to define the environment wherein the older person would be most comfortable. In general, the older person is most comfortable in a situation in which he can pace his responses and is least comfortable in one in which he must respond quickly to demanding sequential stimuli. Rapid sequential stimuli occur, for example, in automobile driving. This situation is not revealed satisfactorily by an analogy to a simple reaction-time experiment. Recent findings in our laboratory show that there is a difference in readiness to respond in the elderly as compared with the young. Different age curves were obtained for changes in response time as a function of preparation. It is not possible to say at this time whether the lower level of response readiness or expectancy is independent of the increased latency or is a different mani-

festation of a common underlying change in the character of nervous system functioning. Also, we do not yet know whether complex tasks merely show a multiplicative effect of the longer latencies. Again it may be that the same basic process is simply disproportionately represented in a complex situation.

Serial Movements in Timing

There is evidence that one of the limitations older persons face is difficulty in timing sequential events. Kay pointed out that his learning experiments suggest that with advanced age some individuals display a difficulty in "programming" sequential movements (1). This was noted also in earlier work on age changes in handwriting. In some aged individuals handwriting tends to become a series of discrete movements, instead of a smooth, overlapping of movements, that is, it becomes more like drawing. This is analogous perhaps to a change in a feedback mechanism wherein the older organism is unable to use the information obtained from the execution of a preceding movement to modify a following one or is unable to do so with sufficient speed. Singleton pointed out that the speed of movements, once the movements are initiated, is unchanged in older persons. What requires additional time with age is the decision points in movements (2).

For optimum skill, the proper moment for initiating responses must be anticipated. Components of serial responses must be programmed in advance to conserve time. If the response components are not anticipated or programmed they appear as discrete events separated by delay intervals. A slowness in developing or programming future responses may limit the aged in the execution of some highly complicated skills, the essence of which is the flowing of activities or movements one into the other. It is perhaps highly relevant to note that, when a skill is first acquired, the component movements appear discrete and that, as the skill is improved, these movements are gradually combined into a continuous pattern. As a skill deteriorates, it may again assume the quality of separate movements. Timing seems to have a perceptual character, that is, one sees or feels the right moment to make a response. Difficult

conditions exist when the signals come close together.

In the preceding remarks, the facilitation of voluntary response was emphasized. However, in the aging nervous system there may exist a general change in excitability which would be reflected in both facilitatory and inhibitory functions of the nervous system. Perhaps more common in daily life than a demand response to a stimulus is the situation in which the stimulus may be anticipated and received in advance of the appropriate moment for the response. Good timing may thus be more a matter of inhibiting the response until the proper moment than a matter of its facilitation. In aging there may exist a narrowing of the range between minimum response time and maximum response time. This topic requires more information than now exists about the length of delays which can be interpolated between sequential stimuli without the behaviors disintegrating or being forgotten.

Viewed from one aspect, the nervous system appears to be more determinate in the aged than in younger persons, that is, the output tends to be more directly a function of the input. There is, of course, a tendency to cultivate certain types of determinacy or redundancy, as in the social graces. It is of interest to note that the social facade may be the last bit of behavior to disintegrate in the senile individual. Our psychological data on aging should be sifted for influences of our cultural pattern that determine which areas of our behavior may be novel and which are expected to be predictable.

Perceptual Difficulty

Perceptual difficulty, or inability to perceive information in order to achieve an appropriate response, may contribute to the age changes in behavior. One experiment attempted to see to what extent the response time of old and young people would vary as a function of perceptual difficulty (16). Young and elderly subjects were required to judge which of two simultaneously presented lines was the shorter. The lines were presented tachistoscopically. Each subject made a minimum of 48 judgments in a series of line pairs which differed in length from 1 to 50 percent. The subject was required

to respond as quickly as he could when the lines were presented by saying "right" or "left" to indicate the side of the shorter line. The vocal response of the subject interrupted a chromosome circuit, and his response time was measured to the nearest one-hundredth of a second. A significant difference in response time between the two age groups was found at all levels of difficulty of judgment. The response time of the elderly was relatively longer, however, when the stimulus difficulty was increased. Thus, the difference in response time between the young and the elderly subjects was 0.47 seconds at a 1 percent difference in line length, whereas for a 50 percent difference in line length the response time of the young and older subjects differed by 0.18 seconds. It is apparent that perceptual difficulty can contribute to the slower response of elderly subjects. However, there is a residual age difference in response time which exists regardless of the ease of the perceptual task involved.

Again, one might question whether a large part of this difference in response latency is not due simply to the difference in speed of vocalization. For this reason we conducted another experiment in which we studied age differences in finger, jaw, and foot reaction time to auditory stimuli (14). The hypothesis was that, if a general factor were underlying the age change in response latency, we would get a constant increment in reaction time with the jaw, finger, and foot. If the age changes were primarily involved in the peripheral pathways, then the reaction time with the foot with its long pathways might be disproportionately slow as compared with the finger or jaw. In this study, the reaction time of the elderly subjects was significantly slower than that of the young subjects for the finger, jaw, and foot, but there was no relation to the length of the peripheral path involved. Since the age differences between the reaction-time means did not change significantly in comparing the finger, foot, and jaw, it may be concluded that the age change in reaction time is not a variable associated with the length of the peripheral path. Collectively, the evidence suggests that it is plausible to regard the age change in response latency as a general property of the central nervous system.

Summary

For many psychological and biological processes there is a general age trend which in some instances explains about 50 percent of the variation in the data. There is an equally large range of individual differences. It depends upon our purposes whether we study and emphasize the general age trend or the individual differences in aging. Both the general age trend and individual differences are important.

Perhaps the most significant result of research on age changes in the nervous system is the implication that there is a generalized slowing of all voluntary responses. On the whole, the evidence indicates there are grounds for regarding the age change in response latency as a general property of the central nervous system. The longer response latencies appear to have their greatest consequence for complex or serial activities. The facts offer suggestions for further research into the bases of the changes, as well as for structuring the environment in order to reduce problems of living due to the psychological limitations of aging.

Making Health Visible

Among the exhibits and other educational materials offered by the Cleveland Health Museum in its catalog, "How to Make Health Visible," three illustrated on this page are among those which particularly concern the subject of age. One is a device which permits visitors to learn the average life expectancy, according to present mortality tables, for their age and sex. Another illustrates the point that aging begins with mitosis. The third illustrates the gain in hearing deficiencies with advancing years.

Changes in Nervous System With Age

By HARRY H. WILCOX, Ph.D.

THE NERVOUS SYSTEM is unique and its basic cellular structure is very highly specialized and diversified. The individual nerve cells in one small circumscribed area or nucleus may be markedly different in structure, action, and reaction from those neurons that form an adjacent group. These neurons, even with their many unsolved problems, are far better known anatomically and physiologically than the greater bulk of the nervous system, their supportive structures. These structures, including the glia and the ground substance, are within the bounds of the existing frontiers of neuroanatomy and neurophysiology. So much of the normal picture of the nervous system is so scantily known that departures from the normal are at best determined with difficulty.

A host of neuroanatomical alterations in the nervous system accompanying the process of aging have been described. Many of these so-called manifestations of aging occur in the very young as well as in the old. Some of these, when they occur in the young are undoubtedly abnormal, whereas the frequency with which they occur in the old might cause them to be labeled as normal alterations accompanying aging. Aging should be looked upon primarily as a physiological stage and not a pathological condition. The normal alterations that bring about or occur with the gradual and continual advance from one plateau of life to another are apt to be quite subtle. They therefore are dif-

ficult to determine or locate accurately, and difficult to separate from abnormal changes brought about by modifications in internal or external environmental conditions as influenced by disease or trauma. The separation of these changes from artifacts or post-mortem changes, often uncontrollable in human material, cannot be overemphasized.

In human peripheral nerves it has been shown that there is an increase in connective tissue and a reduction in the patency of the blood vessels (1, 2). This begins in the fourth decade of life as an endothelial proliferation and hyalinization of the vessels with an increase in the endoperineurium invading and apparently replacing areas of the nerve bundles by connective tissue elements. With this gradual reduction in blood supply and increase in connective tissue, there seems to be a gradual alteration and reduction of the nerve fibers, especially the larger ones. These findings parallel the measurements of the conduction velocity in human nerves (3) which indicate that, beginning in the fifth decade of life, there is a slight but continual decrease in conduction velocity. Again the responsibility may be placed on a decreased vascular supply due to a local ischemia and changes in permeability of the vessels accompanying metabolic depression.

The conduction velocity of peripheral nerves in the rat (4) markedly increases during development, with a leveling off at maturity. In contrast to findings of the human studies, little change in conduction velocity was noted in rats after maturity was reached.

Counts of fibers in the dorsal and ventral roots of the eighth and ninth thoracic levels, as

Dr. Wilcox is associate professor of anatomy, University of Tennessee Medical Units, Memphis.

well as cell counts of those dorsal root ganglia, taken from human cadaveric material (5, 6), indicate a marked decrease in both number of myelinated fibers and cells after the fifth decade of life. However, in view of the rather wide range of variation within the relatively small groups of similar ages in these studies and the degree of overlap between groups, additional studies of this type are needed to substantiate the existing evidence.

Certainly, if in the normal course of aging, the metabolic activities of peripheral nerves are so disturbed as to produce a marked numerical decrease in the components, the effect on the normal course of the processes of degeneration and regeneration might be quite marked. One study of the effect of age on wallerian degeneration in the rat was carried out on fairly young animals (7). In this study it was demonstrated that in young animals there was a more rapid cellular proliferation and a less rapid loss of myelin than in older animals (160 days of age). Another report (8) demonstrates that in older animals more general and extensive signs of retrograde degeneration were present than in young animals, with a striking increase in the number of macrophages present in the sectioned dorsal roots of the older animals, but with a slower rate of removal of debris. This might be due to a lower metabolic rate, although it is not entirely in keeping with the findings of a comparable nerve fiber regrowth rate as evidenced by similar numbers of regenerating axons distal to the anastomosis. In the older animals, there was a diminution in the number of fibers successfully crossing the scar and in the rate of growth beyond. The proliferation of capillaries in the anastomosed roots of the senile rats was quite impressive.

Ganglial Degeneration

Cells of the dorsal root ganglia and the gasserian ganglion in the human, as well as in cats and rats (9, 10), undergo a fatty degeneration which consists of a clumping of the Nissl substance, a subsequent destruction of the neurofibrillar reticulum, and a coalescence of the vacuoles. The cell becomes quite foamy and swollen and finally is destroyed, leaving behind only cellular debris. Although cell counts made on

this material indicated no marked difference between young and old individuals, the numbers were relatively small, and statistical measures could not be applied to test the data. Atypical cells, such as the frayed cells of Cajal, fenestrated cells, cells with end bulbs, and so on, seemed to occur commonly in these ganglia at all ages.

Degenerate changes in occasional cells with a moderate degree of neuronophagia have been reported in human autonomic ganglia, with an increase of the interstitial tissue of the ganglia (11), as well as variations in the chromidial substance, shrinkage, hyalin degeneration, hydropic alterations, pigmentation, nuclear displacement, vacuolization, and partial or complete destruction of the cell (12). While in dogs, many of these variations seem to be related to aging, there was some question about the correlation in man. Even pigmentation was questionable since in man apparently many factors contribute to deposition of pigment.

A subsequent study of this pigment (13) found it to be a lipofuscin type closely related to ceroids and not to melanin. It seems to be one of three materials present in the nerve cells that are periodic-acid Schiff positive. The other two are glycogen, which is found in dogs of all ages, and a mucoprotein. Lipofuscin was not found in dogs less than 10 years of age, while in man it was present in varying amounts at all ages from 7 to 92 years. The mucoprotein is limited to nerve cells of the peripheral nervous system and is present to a greater degree in the autonomic cells. It is present in all nerve cells in a granular form in both senile and young dogs but is not concentrated enough in the young animals to be demonstrated by the periodic-acid Schiff method (14). Lipofuscin has a much wider distribution and seems to be more concentrated in the efferent nerve cells.

The pigment of the autonomic ganglion cell has been considered (15) to be, or to contain, a hormone or a similar substance which represents part of the neurosecretion of the nervous system. The origin of the pigment from the Golgi apparatus has been suggested.

The variability of the Nissl pattern and of the number of cells in the chain ganglia of similar size has been shown in the rat (16) and in the guinea pig (17). The series of animals used

in these studies did not, unfortunately, include senile forms, but the series from fetal to mature stages form bases for further investigation.

No data on the effect of age on the regenerative capacity of the fibers of the autonomic nervous system exists. It would be most interesting to follow this process in senile forms.

Central Nervous System Changes

Changes similar to those described in the ganglion cells are reported in the various areas of the central nervous system. In the spinal cord (18), the general histological structure begins to alter after 30 years of age, and by 60 years the changes are quite marked. Vascular alterations, gliosis, and demyelination, especially in the fasciculus gracilis, pigmentation of cells, and formation of corpora amylacea were among the findings. Pyknosis and chromatolysis in the cells of the ventral horn did not occur frequently and certainly were in no instance pronounced enough to be significant.

Pigmentation was such a constant finding in individuals in the fifth decade of life and older that it was felt that if pigment atrophy is considered an abnormality one could scarcely find a normal spinal cord after the age of 40 and, by the seventh and eighth decades, hardly a normal ganglion cell could be found. In some cells the change was so severe that the cell appeared as a pyknotic pigment spot. Corpora amylacea were not reported in spinal cords of persons less than 30 years of age; after the fourth decade it was a frequent occurrence, especially around the entrance of the dorsal roots.

Changes in the Brain

Several studies indicate that the gross weight of the brain decreases with age. One of these (19), a study on 2,060 brains of white males whose ages ranged from 12 to 96 years, reported that there was a gradual increase in the weight of the brain up to 30-34 years of age, and then a gradual, uniform decrease takes place. The maximum decrease occurring between the 3d and 10th decades of life was approximately 11 percent. Accurate determination of the weight of the brain is quite difficult. It has been pointed out (20) that simple severance of the

brain, the treatment of the meninges, and the removal of the cerebrospinal fluid are rather variable factors (20). These sources of error can be minimized if one individual removes and handles the brains; otherwise, those variables must be considered in analyzing samples.

The brain size has been said to fluctuate inversely with economic level (21). Since most of the brains obtained in routine autopsy in hospitals come from persons of the lower social strata, they may not be too representative of a cross section of the total population.

The reported decrease in brain weight does not seem to be due entirely to a difference in water content. There are studies that report a definite decrease in water content in the brain throughout the entire life span (22, 23). This decrease varies somewhat with different species since there seems to be a remarkable correlation between physical and mental development at the time of birth and subsequent water loss. One report on senile human brains differs from the others in that it states that there is an increase in the water content in senile brains (24). There seems, however, to be universal agreement on the higher water content of the cortex and the lower water content of the medulla, which has suggested that the phyletically newer parts of the brain are wetter.

Phyletically different brain areas also seem to show differences in the cholinesterase activity (25). In rabbits, the medulla reached its maximum activity at 15 days and then fell 50 percent by 2½ months of age. The activity remained fairly stable after that time. In the frontal cortex and caudate nucleus, the maximum activity was reached at 18 months and then held steady. However, no general conclusions as to the correlation of the cholinesterase activity have as yet been made with senility.

Young and adult rats differ in that the adult brain contains more fat and phosphorus. In extreme age there are small decreases in fat, acid soluble phosphorus, and potassium, with an increase in sodium (23).

The cerebral physiology of the human has been studied by the nitrous oxide method to show that there is a close correlation between advancing age and decreasing blood flow with a concomitant decrease in oxygen consumption (26, 27). This decrease in oxygen availability

and consumption may be closely related to neuronal activity. There seems to be almost universal agreement that, with increase in age, there is a marked decrease in the number of neuronal elements in the brain. However, most of the observations and cell counts upon which this conclusion is based have been made on relatively small series of human brains, even on a single specimen and with known mental deterioration frequently clouding the issue. Counts on large series of experimental animals are likewise scarce.

A recent report shows a decrease in the number of cortical neurons with increasing age, especially in the superior temporal gyrus and the lower quarter of the precentral gyrus (28). Unfortunately, this study is based on a very small sampling of a remarkably variable population. Variability is immediately apparent when one examines the raw data presented by the various investigators.

Only by the use of large samples, which in studies of this kind are most difficult to procure and study, can this source of error be overcome. It is indeed reasonable to believe that, in a cell which has lost its ability to reproduce and which functions more or less constantly over the years, physiological and anatomical deterioration can readily occur either as a perfectly normal process or as a consequence of some external or internal environmental disturbance. Therefore, not only is the mass of evidence—even though still circumstantial and not entirely conclusive—in favor of the decrease in cell numbers with age, but it seems logical to expect it. I merely point out here that there is still a great need for quantitative studies on the brains of humans and experimental animals, quantitative studies that consider variables and try to control them. Proof for one species cannot necessarily be had from studies on another, since it appears more and more that there is a marked difference in the aging of the nervous system in different species.

Purkinje Cells

The population of the Purkinje cells is reported to suffer severely with advancing age. In a description of the Purkinje cells of a 92-year-old man, it was stated the cells "appear

considerably shrunken, both nucleus and protoplasm, though not more so than normal daily fatigue" (29). This individual was in a coma and endured 6 days of inanition prior to death. The Purkinje cells were reported to be 25 percent fewer than in the cerebellum of a 47-year-old man. In another study of the cerebellums from 63 humans of both sexes, aged 12-92 years, 43 cerebellums were eliminated from consideration because they "showed the greatest losses," and "cell losses are frequently due to disease" (30).

Similar decreases in Purkinje cells in the dog, the macaque (31), and the rat (32) are reported. Reducing the rat to the equivalent age of man, it was concluded that destruction of the cells or the processes leading to destruction take place 30 times as fast in the rat as in man.

A loss as high as 40 percent in the Purkinje cells of guinea pigs has been reported (33). However, this figure is based on the number of cells in the newborn as 100 percent, and it is important to note that the highest percentage loss—66.7 percent—occurred in one animal of 193 days of age (34). In one area of the cerebellum, 7 animals out of the 10 younger than the oldest (1,800 days) of this series showed more loss of Purkinje cells than did the oldest animal.

In my own series of guinea pigs, whose ages range from 139 to 2,765 days, I have been unable to measure quantitatively any loss of the Purkinje cells. On the contrary, the population seems to be quite stable, and certainly there are no discernible areas in which cells have degenerated and have been removed.

Pigmentation

Almost every conceivable cytological alteration has been described and associated with age changes (33). These alterations are not restricted to any one part of the brain but seem to occur everywhere. Of these, "the most constant element indicating aging in nerve cells is lipofuscin, the lipochrome pigment. It rarely appears in younger subjects, but does appear beyond a certain age. . . . while we can get lipofuscin in some pathologic conditions, the truth is that we can get a great deal of

this material in elderly persons. . . . this is the most important element shown in the cell and that other elements, such as variation in the neurofibrils, Golgi apparatus and, in some cases, the Nissl bodies will have a secondary place" (35).

The accumulation of pigment occurs at different time intervals in different regions. Certain nuclei are prone to early pigmentation; others fail to show pigment even in advanced age. It has been suggested that constantly activated cells are less prone to pigmentation, while those that undergo periods of rest or inactivity are more likely to become pigmented during the aging process (36-38). In this connection, it is interesting to note that the accumulation of pigment in the nerve cells, as well as some of the other changes with age, are more marked in the human species than in other mammals (33).

The Glia

The role of the glia in aging is undoubtedly a very important one, although, except for the phenomenon of satellitosis, with the concomitant process of neuronophagia, little is known about these structures. Studies of satellitosis and neuronophagia of the cortical cells of the human (39) and of the horse (40) report definite, increasing occurrence with advancing age. In the rat and mouse, satellitosis was not nearly so marked (41a). This process also occurs in the brains of young animals and humans, where it may be even more frequent than in the very old individuals (41a). No marked qualitative change in glial cell types participating in this process has been reported (41b).

Ante-Mortem and Post-Mortem Changes

In the human and in the experimental animal, it is at times extremely difficult to separate the changes which can occur in the cells of the brain before and after death. Post mortem artifacts are real stumbling blocks in neurohistological studies and should not be underestimated. I personally do not contend that nerve cells do not show signs of degeneration, die, and are removed by phagocytosis or lysis. However, I do feel that we must proceed as cautiously as

possible in our interpretations of what is normal and what is abnormal in the aging brain.

C. Vogt and O. Vogt (36) point out that the time course and morphologic features of aging are different in each of the hundreds of different cell types, and that "the aging process or 'involution' of a cell is different from any regressive process of 'degeneration' it may undergo, but degenerative processes may, of course, occur in combination with an involution. . . . The aging process always leads to the death of the cell. If it occurs at an average (normal) time, it causes partial death of the brain through normal death of the cell type in question. If a person lives sufficiently long, partial death of the vital cells of the medulla causes his or her death, as a normal phenomenon. This form of death is a rare occurrence, because death through disease usually terminates the individual life at an earlier stage." These authors suggest that the aging process may produce counter-reactions, such as hypertigrosis produced by the increased activity of the nucleolus, or hyperchromatosis and pyknosis of the nucleus which has hitherto been wrongly interpreted as a degeneration. This reaction as a defensive or compensatory change on the part of the individual nerve cells may include division of the nucleoli and the nuclei of the cells as well (33).

Physiological Limitations and Age

By JOSEPH A. FALZONE, Jr., M.D., and NATHAN W. SHOCK, Ph.D.

THE PHYSIOLOGY of aging in man rather than age differences in disease incidence has been the chief concern of the Gerontology Branch of the Public Health Service's National Heart Institute. A large body of this latter information is available from other sources (1, 2). In the course of our studies, we have found that aging does not affect all organ systems in the same way.

It is obviously difficult to define rigorously what should be called senescence as opposed to "disease." We can only hope to describe changes that occur with the passage of time in subjects for whom all diagnosable disease, which would affect the organ system under study, has been ruled out. To do this, we apply what we call "uniform subject selection criteria" so that other investigators will know what we mean by the phrase "healthy normal subject" and can judge the results accordingly.

The most basic principle of physiology is that the function of most organ systems is to maintain constancy of the internal environment. This is the principle of homeostasis as advanced by Bernard, Cannon, and others. We therefore require three types of information to characterize physiological age differences effectively.

1. The resting state of the internal environment.

2. The resting organ functions that maintain this state.

3. The reserve or maximal capacities of these organ systems and their ability to defend the internal environment against displacements induced by stress.

The Internal Environment

Under resting conditions, the internal environment is surprisingly well preserved in the older individual as evidenced by lack of change in body temperature (3) and levels of various substances in the blood. Thus, Shock and Yiengst (4) found that the acid-base equilibrium of the blood is maintained within normal limits in the old man (fig. 1). A slight fall in pII does occur with corresponding, but not significant, changes in CO₂ tension and bicarbonate level.

Arterial fasting blood sugar does not change significantly with age (5), but there is some evidence suggesting a slightly higher fasting level in venous blood (6).

Hematological values of the blood are also well maintained in the aged. Shapleigh, Mayes, and Moore (7) determined these values in a series of 100 men and women 60-95 years of age and compared them with previously reported values for healthy young adults. Red cell counts, hemoglobin, and hematocrit values were slightly, and probably significantly, lower in the 60-95-year age group, with a smaller sex difference than in young individuals. Red cell

indexes and reticulocyte counts remained within the normal range, and no definite qualitative erythrocyte changes were seen microscopically. Total and differential leukocyte counts were also unchanged.

Functional Measures

It must be emphasized again, however, that the data described so far tell us very little of function or reserve capacities of the system for meeting the stresses of daily living. For example, if an individual's daily urea production remains constant while some renal insult suddenly reduces urea clearance, his blood urea will gradually rise until the product of blood level and clearance is once more equal to this tissue production rate. This new steady state level of blood urea will then be evidence of impaired renal function. It is also evident, however, that this same individual, if placed on a low protein diet at the same instant as his renal damage, might show no elevation of blood

Figure 1. Trends in the acid-base equilibrium of the blood of men with increasing age.

Average curves from top to bottom include percentage of red cells, serum pH at 38° C., carbon dioxide tension expressed in millimeters of mercury, and serum bicarbonate and blood carbon dioxide content, both expressed in millimoles per liter. The vertical lines indicate ± 1 standard error of the mean.

urea. Theoretically, then, physiological functions and reserve capacities can be reduced enormously without change in the internal environment, under resting conditions. In this regard, many of you will recall patients with a progressive downhill course and eventual death despite an impressive list of normal blood chemistries.

Among functional measures that can be employed, the basal metabolic rate (BMR) is of obvious interest in agewise comparisons. One often hears the suggestion that people "slow down" as they grow older, as evidenced by obvious changes in speech, gait, and cerebration. The ultimate energy source for all of these functions is, of course, oxidative metabolism. Without implying a causal relationship, one might ask if this overall metabolic rate also declines with age, at least under resting conditions. This appears to be the case. Shock and Yiengst (8) demonstrated a significant age decrement in basal O_2 consumption whether expressed as total oxygen uptake for the individual or per unit surface area. Expressed in calories per square meter per hour, the decline is from approximately 36 at age 40-49 to 30 at

age 80-89. This is not dramatically large, but it is highly significant and agrees quite well with most other data. Later, we will have reason to question the adequacy of calculated body surface area as an index of the amount of functioning tissue present in the individual. The fact to be emphasized at this point is that oxygen consumption per individual decreases with age.

A decline in resting cardiac output and cardiac index was found in a series of 67 men by Brandfonbrener, Landowne, and Shock (9), as shown in figure 2. This, of course, tells us nothing of the reserve capacity of the heart for increasing its output under conditions of exercise. We have recently initiated a study designed to give us this information, using exercise carried to exhaustion as the maximum stimulus to cardiac output.

Pulmonary function, in the aspects we have measured, changes markedly with age (10). Thus, total lung capacity (TLC) declines, but in our sample of 140 subjects this is paralleled by a decline in surface area. Total lung capacity corrected for surface area does not change. The compartments of total lung capacity change strikingly, however, with an increase in residual volume (RV) at the expense of vital capacity (VC) and its subdivisions. Thus, there is a shift from mobile to fixed lung spaces. The other large change we have found is in maximum breathing capacity. This falls

from a mean of about 132 liters per minute at age 20-29 to 50 liters per minute at age 80-89. Most of this impairment seen in the older individual is a result of a relative inability to increase respiratory rate under the test conditions.

It may be suggested that our older subjects are suffering from emphysema. Certainly, we cannot distinguish these age changes from emphysema, particularly if an arbitrary value of the ratio of RV to TLC (or VC) is to be the clinical criterion, as it often is. We can only suggest that this common form of emphysema is a relatively constant age change and that the term "senile" emphysema is appropriate.

Of all organ systems maintaining the internal milieu, probably none bears a greater burden than the kidney. The arterial blood reaching the kidneys passes through the glomeruli; of this, about 20 percent is filtered through the glomerular membranes. About 99 percent of this filtrate water is actively reabsorbed by the kidney tubules, together with glucose, amino acids, and electrolytes, while waste products are excreted into the remaining filtrate volume by these same tubules. The external product is urine of variable composition; the internal component, blood plasma of constant composition. Thus, a complete estimate of renal integrity includes measures of the amount of blood or plasma perfusing the kidney, the proportion of plasma filtered, or the filtration

fraction, the amount of glomerular filtrate formed, and the maximum capacity of the tubules to reabsorb or excrete specific substances.

It is found that renal plasma flow, as measured by diodrast clearance, decreases from about 600 cc. per minute in the 20-29-year age group to about 300 cc. per minute in the 80-89-year age group (11, 12). Figure 3 shows a scatter plot of these individual values. It may be seen that some of the 80-year-old subjects have values at least as high as some individuals in the 40-50-year age group. One wonders what values these 80-year-old subjects would have shown in their youth. This variability is seen in many other functions and only stresses the need for longitudinal studies in aging since individuals might show stepwise decrements in function.

Glomerular filtration rate, as measured by inulin clearance, also declines with age as seen in figure 4 (11, 12). This is slightly less than the decline in effective plasma flow so that the filtration fraction increases slightly, but significantly, as shown in figure 5.

From these data alone, we cannot say whether the reduced plasma flow results from loss of nephrons, reduced flow per nephron, or a combination of these two factors, but the increased filtration fraction would imply a relative increase of efferent to afferent arteriolar constriction. It would also appear that total renal resistance has increased more than total peripheral resistance, since the age decrement in

renal blood flow exceeds that in cardiac output (9) while mean blood pressure does not fall.

Are the apparent changes in the resistance of the kidney to blood flow the result of unalterable anatomic changes in the arterioles or can resistance be lowered by a physiological stimulus? To answer this question, McDonald, Solomon, and Shock (12, 13) tested the effect of a bacterial pyrogen which increases effective plasma flow in young subjects. It was found that effective plasma flow could be increased significantly in all age groups, and that while the absolute baseline and magnitude of increase was smaller in the oldest group the percentage increment was similar to that of the young. The glomerular filtration rate was unchanged by the pyrogen while the filtration fraction necessarily declined significantly to become equal in all age

groups (fig. 6). This suggests that a large proportion of the total as well as relative efferent vasoconstriction present in an old kidney is reversible (14).

It was also found that tubular function, as estimated by maximum rates of diodrast excretion and glucose reabsorption, decreased with age, as shown in figures 7 and 8 (11, 12, 15). The magnitude of these decrements is similar to that of glomerular filtration rate (GFR), which suggests that nephrons lose function as a unit. Constancy of the ratio GFR: diodrast T_m is seen in figure 9. The decline in effective plasma flow, however, exceeds any of these decrements, suggesting that vascular impairment is primary rather than secondary to loss of nephron function (11, 12). This relationship is illustrated in figure 10.

Possible Effects on Longevity

What do these changes mean with respect to health, vigor, and life expectancy? They are certainly never listed as cause of death. Yet we may ask if they are in some way related to the unfortunate contour of mortality curves—something happens to the individual with time so that probability of death at any moment is not constant but increases with age. This can be illustrated by the results of renal studies. It is known, for example, that urea and inulin are excreted by the kidney in a similar way except that some of the urea diffuses back into

Figure 7. Change in standard diodrast T_m with age.

the blood stream. Thus, we would expect urea clearance to show an age effect similar to that of the glomerular filtration rate and also to find some increase in blood urea nitrogen unless an older man's nitrogen catabolism is reduced in a parallel way.

Studies by Lewis and Alving (16) do show an age reduction of urea clearance of about the same magnitude as the fall in glomerular filtration rate as found in our laboratory. An older man's nitrogen catabolism is reduced, but only slightly, and this is not enough to prevent an increase of blood urea nitrogen from 10 mg. percent to 18 mg. percent over a 20-90-year age span. This relationship between blood level clearance rate and production of urea is a simple hyperbolic one, that is, successive constant decrements of urea clearance produce ever larger increments in blood urea.

From this and from the Lewis and Alving data, we can make a simple prediction. Suppose that a 20-year-old man suffers some renal insult such as nephritis or ureteral occlusion which reduces his urea clearance by 25 percent. As a consequence his blood urea nitrogen will increase from approximately 10 to 13.3 mg. percent, or a rise of 3.3 mg. percent. This is still within the limits of normal. If, on the other hand, a 90-year-old man suffers the same fate,

his blood level will rise from 18 to 23.9 mg., an increase of 5.9 mg. percent, which is above the normal range. Further renal insults will serve to magnify this difference. Urea itself is relatively nontoxic, but impairment in reserve will make the accumulation of substances in the body more rapid, and the deleterious effects of toxic substances will be more marked in the old man.

It is more difficult to make predictions with respect to pulmonary function. Although the maximal breathing capacity is normally much higher than the ventilatory level attained with violent exercise, it is quite likely that there is a correlation between the two levels, and we have some preliminary findings which support this. However, by making a variety of assumptions with regard to dead space and tidal volume, it can be calculated that ventilation volume per se does not limit the oxygen uptake or exercise performance of an older man until values below 20 liters per minute are reached. As these calculations were designed to demonstrate the effect of ventilation alone, they assume perfect mixing of air in the lungs. Since mixing is not perfect, the age changes in lung compartments we have observed would tend to impair lung transport and thus produce arterial oxygen unsaturation and undue demands upon cardiac output at ventilation volumes higher than calculated. Thus, we see that an impairment in one physiological system places an added bur-

Figure 9. Change in rate of glomerular filtration per unit of diodrast T_m .

Figure 10. Change in effective renal plasma flow per unit of diodrast T_m .

den upon another system whose functional capacity may also be decreased with age. What we have observed so far is that the maximum work rate of an old man is reduced; we are now trying to discover the relative importance of pulmonary, cardiac, or muscular limitations.

It is also not too difficult to imagine an adverse effect of pulmonary limitations upon life expectancy. For example, an older individual with reduced ventilatory capacity and mixing efficiency is in a far more precarious position with superimposed lobar pneumonia than is a young man.

Mechanisms of Aging

We have described some physiological age changes in man, with some possible consequences with respect to vigor and longevity. We must now ask how these changes come about. It is apparent that functional loss in an organ system implies either loss of active protoplasm or qualitative difference in the protoplasm. To estimate the relative importance of these two factors, we obviously need some good index of protoplasmic mass. There is quantitative histochemical evidence that, for a given tissue, protoplasmic composition is relatively constant with respect to water and electrolytes and does not change with age (17). Thus, intracellular

water, which can be estimated in intact animals, should serve as a better protoplasmic index than body weight or calculated surface area, which are obviously affected by such nonprotoplasmic materials as fat and edema fluid.

By using the antipyrine space as a measure of total body water and the thiocyanate space as an estimate of extracellular space, the intracellular water may be calculated as the difference between these two. Shock, Yiengst, and Watkin (18) found that total body water and intracellular water decrease significantly with age while the extracellular space does not change. Since these estimates were made for the same subjects used in studying the basal metabolic rate, they could be applied as BMR reference standards for each individual. It was found that basal O_2 consumption per unit of total body water or intracellular water does not change with age (fig. 11). This would suggest that, in terms of net metabolic activity, the protoplasm of an old man is unchanged; he simply has less protoplasm (19). Morphological studies of a variety of tissues in man support this viewpoint. Thus, a variable weight loss of many organs occurs with age, accompanied by widespread cell shrinkage, cell loss, and relative or absolute fibrosis (20).

Qualitative cellular changes are equally interesting. Nuclear abnormalities (21, 22) and vacuolated mitochondria (21-24) are observed as well as deposition of highly insoluble "age" pigments in heart, brain, and adrenal (21, 25, 26). Lansing (27) has summarized evidence for a loss of cell permeability accompanying increased calcium binding of the cell cortex. The implications of these changes, with respect to cell function, are intriguing, but can we say they are primary changes? We must ask another fundamental question posed by the overall histological appearance of old tissues: Does the intercellular material passively replace cells which shrink or die as they grow old or do the cells die only because they are literally strangled by connective tissue which ages and loses permeability? Or are both altered independently?

In some organs, such as the liver and adrenal, cell shrinkage and loss overshadows fibrosis and might, therefore, be considered a primary factor (20). However, the absence of dramatic morphological change in a tissue does not rule

out the possibility that subtle alterations, such as reduction in blood flow or permeability, play an important role in aging. In other organs, such as the kidney, parenchymal changes may be secondary results of vascular lesions. It is possible that all of the renal age changes are secondary to progressive arteriolar change (20). The fact that the age decrement in renal plasma flow exceeds loss of tubular function would support this view although we can hardly cite it as proof. We cannot be sure that the nephrons would not eventually age in the absence of vascular changes. In short, we have no proof as to the primacy of either intracellular or extracellular changes as the basic cause of aging.

Lansing has summarized some evidence for the hypothesis that aging is a consequence of growth cessation (27). His own work shows that longevity of rotifers is inversely proportional to maternal age, that this effect is cumulative through successive generations, and that this progressive shortening of life span first appears when maternal age exceeds the growth phase of this organism. Lines of rotifer, with constant "old" maternal age, were termed "geriaclones" (27, 28).

Experience with tissue culture tends to reinforce this concept, but in a less definite manner. Thus, many cell types show unlimited

Figure 11. Age changes in basal heat production

SOURCE: Reference 19.

growth potential in vitro (29). Even adult human neurones have not entirely lost the capacity for mitosis, as shown by Murray and Stout (30). It is of interest that only neurones relatively free of age pigments were observed in mitosis. However, the experience with neurones and other cultures reveals a general antagonism between growth rate and tissue organization (29-31). Cell lines, with high growth rates may survive indefinitely but show poor differentiation, while slowly growing cultures show more organization but are difficult to maintain. In fact, nonmitotic cells in culture generally live only a fraction of their survival time in vivo so we cannot yet say that they "age" as a consequence of growth lack; they simply do not survive or have not been observed for a sufficient length of time (29). Perhaps culture methods can be improved to the point where we can actually decide whether such cells inevitably age in the absence of their normal connective tissue environment. Obviously, this could be most easily tested with cultures from short-lived animals. Neurones from rat and man are morphologically alike, yet their normal life spans differ by a factor of 30. How would their survival times compare in vitro? So far, all we can say is that in vitro the price of immortality is chaos.

Research Needs

The question of primary causes of aging can be answered only by further research on both the human animal and lower life forms. We have studied many aspects of aging in man in the Gerontology Branch, but this field is far from exhausted. As a single example, we have seen that hematological values are only slightly altered with age, but we need information on the rate of replacement of plasma proteins, red cells, and leukocytes. We would also like to know the factors producing the great individual variability we have observed. Why do some 80-year-old men have the physiological reserve of men 30 or 40 years their junior? In this variability lies hope, if we can discern its cause. Longitudinal studies are pertinent to this question. The Gerontology Branch has existed long enough so that we are beginning to gather some of these data on both patients and investigators.

There is, however, information that can only be obtained by animal experimentation, as for example, age changes in tissue composition and enzymatic activity. Such studies on the rat are now in progress in the Gerontology Branch. Some other fundamental researches are best applied to invertebrates, many of which have the twin virtues of uniform genetic composition and very short life spans. The utility of such organisms is illustrated by such excellent studies as that of MacArthur and Baillie (32) on the temperature dependence of life span in *Daphnia magna* or by Lansing's work on rotifers (27, 28). These two studies jointly raise a curious question. The geriacclone rotifers show, in addition to shortened life span, earlier sexual maturity and accelerated growth rate but smaller final size. These are precisely the four effects seen in *Daphnia* raised at high temperatures. Why this should be so we have no idea, but it is obviously an important clue. It is problems like these which urgently require solution. The questions that face us are difficult, but there is no real reason to believe that they are unanswerable.

Summary

Examination of experimental studies on physiological changes with age indicate that, under resting conditions, the aged human is usually able to maintain uniformity of the internal environment. However, when increased demands are placed on a number of organ systems, impairment of function can often be detected. Thus, the primary characteristic of the older individual is a reduction in reserve capacities which makes him more vulnerable to stresses of even daily living than the young. These changes take place gradually over the entire adult life span and may, in part, be attributed to a loss of functioning tissue. The causes of this loss have not been identified. One of the outstanding characteristics of age change is the striking difference in vulnerability among individuals. At the present stage of research, we cannot identify the factors that determine these individual differences. It is not yet possible to determine the relative importance of loss of functioning tissue and alterations in cellular metabolism in producing the age changes in

physiological function which have been observed. Extensive research, including biochemical, physiological, and histological studies on species other than man will be required to answer these important questions.

growth potential in vitro (29). Even adult human neurones have not entirely lost the capacity for mitosis, as shown by Murray and Stout (30). It is of interest that only neurones relatively free of age pigments were observed in mitosis. However, the experience with neurones and other cultures reveals a general antagonism between growth rate and tissue organization (29-31). Cell lines, with high growth rates may survive indefinitely but show poor differentiation, while slowly growing cultures show more organization but are difficult to maintain. In fact, nonmitotic cells in culture generally live only a fraction of their survival time in vivo so we cannot yet say that they "age" as a consequence of growth lack; they simply do not survive or have not been observed for a sufficient length of time (29). Perhaps culture methods can be improved to the point where we can actually decide whether such cells inevitably age in the absence of their normal connective tissue environment. Obviously, this could be most easily tested with cultures from short-lived animals. Neurones from rat and man are morphologically alike, yet their normal life spans differ by a factor of 30. How would their survival times compare in vitro? So far, all we can say is that in vitro the price of immortality is chaos.

Research Needs

The question of primary causes of aging can be answered only by further research on both the human animal and lower life forms. We have studied many aspects of aging in man in the Gerontology Branch, but this field is far from exhausted. As a single example, we have seen that hematological values are only slightly altered with age, but we need information on the rate of replacement of plasma proteins, red cells, and leukocytes. We would also like to know the factors producing the great individual variability we have observed. Why do some 80-year-old men have the physiological reserve of men 30 or 40 years their junior? In this variability lies hope, if we can discern its cause. Longitudinal studies are pertinent to this question. The Gerontology Branch has existed long enough so that we are beginning to gather some of these data on both patients and investigators.

There is, however, information that can only be obtained by animal experimentation, as for example, age changes in tissue composition and enzymatic activity. Such studies on the rat are now in progress in the Gerontology Branch. Some other fundamental researches are best applied to invertebrates, many of which have the twin virtues of uniform genetic composition and very short life spans. The utility of such organisms is illustrated by such excellent studies as that of MacArthur and Baillie (32) on the temperature dependence of life span in *Daphnia magna* or by Lansing's work on rotifers (27, 28). These two studies jointly raise a curious question. The geriatron rotifers show, in addition to shortened life span, earlier sexual maturity and accelerated growth rate but smaller final size. These are precisely the four effects seen in *Daphnia* raised at high temperatures. Why this should be so we have no idea, but it is obviously an important clue. It is problems like these which urgently require solution. The questions that face us are difficult, but there is no real reason to believe that they are unanswerable.

Summary

Examination of experimental studies on physiological changes with age indicate that, under resting conditions, the aged human is usually able to maintain uniformity of the internal environment. However, when increased demands are placed on a number of organ systems, impairment of function can often be detected. Thus, the primary characteristic of the older individual is a reduction in reserve capacities which makes him more vulnerable to stresses of even daily living than the young. These changes take place gradually over the entire adult life span and may, in part, be attributed to a loss of functioning tissue. The causes of this loss have not been identified. One of the outstanding characteristics of age change is the striking difference in vulnerability among individuals. At the present stage of research, we cannot identify the factors that determine these individual differences. It is not yet possible to determine the relative importance of loss of functioning tissue and alterations in cellular metabolism in producing the age changes in

Age Changes and Employability

By L. F. KOYL, M.D., D.T.M.H.

THE Department of Veterans Affairs of the Dominion of Canada is comparable to the Veterans Administration in the United States. Among the employees in its Toronto district, it has about 250 persons who are reaching retirement age each year during the fiscal years 1954-64. The facilities of the DVA's 1,800-bed teaching hospital, Sunnybrook, offered an opportunity to study the problems of these aging employees.

In 1954, the assessment unit of Sunnybrook Hospital was publishing data about the problems of the older deteriorating veteran. We requested and were allotted the problem of studying the whole employee in his total environment. Other studies, including an atherosclerosis project and an arthritis study, parallel our work. If the group studying the aging employee detects a problem of interest to any of these groups, their facilities are available to us. Other DVA hospitals in other university centers have special interests under study.

Our terms of reference are:

1. To study a large group of aging employed persons over a period of years to discover the incidence and the rates and direction of change in the various pathological processes accompanying age, including social, economic, medical, and psychological processes.

2. To establish a valid clinical method of assessing the aging worker as an individual and of comparing him with his fellows.

3. Therefrom, to establish criteria for continued employment beyond fixed retirement ages.

4. Therefrom, to develop a practical method for examination of the aging employee to determine his suitability for continued employment.

5. To study the rate, direction, varieties, and measurement of intellectual deterioration and to develop practical, accurate, and brief testing procedures.

6. To explore the possibility of correlating clinical evidence of deterioration with laboratory evidence in a practical manner.

7. As a corollary to the above, to study (a) the positive prevention of total or partial deterioration in older workers and (b) means of keeping older workers working and free from disability.

8. As a further corollary to the above, to study methods of preparing individuals for successful retirement.

We thus began a 5-7-year study, using the multidisciplinary approach, with medicine, psychology, sociology, and economics all involved. We favor placing no limitations on the inventiveness of our members except the tolerance of volunteers to an examination already requiring 6 hours.

It is difficult or impossible to do quantitative analyses on any except the simplest aspects of human behavior, such as chemistry. We therefore had to devise methods of converting qualitative data into semiquantitative data. We

Dr. Koyl is director, assessment unit, Sunnybrook Hospital, Department of Veterans Affairs, Toronto, Canada, and medical consultant, The de Havilland Aircraft of Canada.

Restorative Services for Older People

The following text was issued in a limited edition as a leaflet for the Federal-State Conference on Aging, June 5-7, 1956, Washington, D. C., prepared by the Hygiene of the Aging Section (now the Health of the Aged Section) of the Chronic Disease Program, Division of Special Health Services, Public Health Service. It is published here to emphasize that many forms of rehabilitation may be constructive, whether or not the patient recovers full physical and economic independence.

There is convincing evidence that a substantial backlog of aged patients for whom restorative services would be appropriate has accumulated in the institutions and communities of this country. All professional workers in the health field should be alive to the opportunity for restoring many of these older people to self-care. The private physician, the health officer, the director of an institution—all should inform themselves concerning the highly significant possibilities in this area.

Restorative services for older people aim at permitting resumption of necessary daily activities by patients themselves through physical and psychological restoration, and at maintenance of maximum self-care by followup procedures. The group for which restorative services are most appropriate is made up of those aged patients who would otherwise be committed to a virtually helpless condition for the rest of their lives, but no disabled patient should be denied services which will maximize his physical and mental capabilities. In certain cases patients not only can be physically restored for daily living so that need for care is reduced, but can, through further rehabilitation, become employable again.

Three questions are significant in this field:

1. To what extent is restoration to self-care possible?
2. What kind of personnel does the job require, and how many?
3. What is the cost of the service?

Results of Restorative Services

Reports on the extent of possible restoration to self-care are not numerous, nor always comparable, but certain salient facts have already been recorded. In England the United Oxford Hospital reported that three-quarters of the surviving patients who received these services were rehabilitated by the end of 3 months. At the District of Columbia General Hospital roughly two-thirds of the patients receiving restorative services returned to the community capable of self-care (including both inpatients and outpatients). At the Allegheny County Home (Pennsylvania) the proportion of patients achieving self-care after restorative services varied from 40 to 70 percent: arthritics, 60 percent; amputees, 70 percent; hip fractures, 60 percent; stroke cases, 40 percent.

Personnel

Ideally, the restorative service team includes: physician director (preferably a physiatrist), psychiatrist, psychologist, physical therapist, occupational therapist, speech and hearing therapist, recreational worker, social worker, nutritionist, and nurse. Few institutions can afford ideal staffing, but much can be accomplished by (a) inservice training of the existing staff, (b) the addition of a few rehabilitation specialists (either full time or on a consulting basis), and (c) the maximum use of community resources.

The Allegheny County Home program is a successful example of what can be accomplished through this approach.

Cost

Accurate cost analysis of restorative service programs cannot be made at this time because of variations in cost accounting and in staff and equipment. For example, the District of Columbia General Hospital charged against these services \$53,501 for treatment of 883 patients over a 14-month period, an average charge of about \$60 per patient treated. On the other hand, the New York University-Bellevue Medical Center estimate for the annual cost of rehabilitation personnel operating a 100-bed restoration service is \$104,000 (unpublished data). Each institution must estimate its own costs. It should be noted that the services normally show successful results within 3 months, if success is to be achieved.

In summary, restorative services for older people have been proven to be effective; it has been established that personnel are available or can readily be trained for this work; the cost of the program can be kept within reasonable limits.

On the basis of these facts, it is hoped that early action will be taken in communities throughout the country to initiate these activities.

Finally, it must be constantly emphasized that this problem and this opportunity confront the entire medical profession; restorative services are by no means limited to institutional situations. Wherever old people can benefit by this type of service—in the home as well as in the hospital or the nursing home—the service should be supplied. This is a medical, a health responsibility. It is a challenge to everyone responsible for the health of older people.

Our estimates of probable change are plotted in the lower half of the chart. It will be noted that age plus 5 years is the abscissa so that the overall pattern is comparable in the two halves of the chart. The artificial cutoff now occurs at age 70. The sharp bends from G5 to G6 and from G6 to G7 are obviously due to the small samples at G6 and G7. Otherwise there is a slight angulation toward the right in both mean and median lines. Such angulation to the right suggests decreasing fitness with increasing age. The standard deviation of G1 is 3.5, which makes this suggestion probable as the mean curve moves to the right at least 7.1 points relative to G1 between G1 and G5.

The number and degree of the pathological processes going on in the middle-aged employee

will be no surprise to the practicing physician although the universality of these processes may be surprising. They become evident gradually in the forties so that the rate of deterioration in health is a straight-line curve to the sixties. Health begins to deteriorate more rapidly as the seventh decade approaches.

Psychological Report

Some Aspects of Intelligence

The calculated intelligence of the volunteer and a clinical prediction of the rate of change shown in figure 2. The prediction in the lower half of the chart is based on clinical evidence from the various types of disease already present and otherwise is based on the pre-

Figure 1. General physique of 150 employees of retirement age. Upper half, results of examination; lower half, estimated probable changes.

- G1 Fit for heavy manual work, including digging, lifting, climbing, regularly as main occupation.
- G2 Fit for manual work, including incidental or occasional heavy work as in G1—can work on shifts.
- G3 Fit for all employment except heavy labor, liable to deteriorate if meals and rest inadequate.

- G4 Fit for sedentary employment with regular hours for meals.
- G5 Fit for restricted employment or part-time employment. "The handicapped worker" in home or out.
- G6 Self-care only.
- G7 Bedfast.

chose functional profiles of our own devising, including the Gulhemp scale. It is important to note the two words "functional" and "profile." A profile can be graphed, machine coded, and so on. If it is a profile of functional ability and is explicit enough, it can be used for job descriptions, employment examinations, and so on.

A most important factor in our work is accuracy of prognosis. We are deliberately making 5-year prognoses when we feel that we have the knowledge to do so and we shall check the accuracy of the prognoses by seeing all volunteers again at 2½- and 5-year intervals. We have already made many repeat examinations for reemployment after age 65 and have been pleased to see that we are very close in our estimates of the type and direction of change in pathological processes. How accurate we are in our estimates of the rate of these changes will not be known for a few months.

Medical Report

There is no real difference in the type of disease found in the working population in this study (median age 61.05 years) and the type found in deteriorating veterans (median age 70.0 years) applying for domiciliary care (1,2). The difference found is one of degree.

A discussion of preliminary findings follows. The work of our medical and psychology workers is emphasized since reports on the social and economic aspects of the study have been published (3).

In only 6 of the 150 volunteers could the diagnosis of "no appreciable disease" be made. However, all were working; therefore, none were truly disabled.

There were 65 fixed disabilities, mostly from wounds, injuries, and operations. Osteoarthritis caused recognizable symptoms and signs in 38 persons. Varying degrees of atherosclerosis were observed in 33 persons, 2 of whom have since died after massive coronary occlusions. Other disease processes were observed in 119 persons. Varicose veins were a problem in 13. Varying degrees of deafness were noted in 33, while 78 had decreasing visual efficiency. There were 8 possible premalignant skin lesions.

Laboratory Findings

In all 150 volunteers, the hemoglobin reading was over 80 percent; the average was 90 percent (15.6 gm. percent=100 percent).

In 24 of 60 cases the sedimentation rate was over 20. Two females were not counted as abnormal because their rates were marginal (22 and 24); in the remaining 22, none of the usual causes of an elevated rate were present.

Results of 24-hour steroid tests on 60 cases were as follows:

Test	Num- ber cases	Range (mg. per- cent)	Average (mg. percent)	
			60-65 years	49-59 years
17 ketosteroids-----	30	5-15	6.8	6.8
Crude corticoids-----	{ 29 1 }	{ 1-3 3.8 }	1.7	1.8

The frequency of abnormal sedimentation rates is interesting. Possibly emotional stress due to the prolonged examinations caused this abnormality. Two-thirds of all abnormalities were recorded at 4:00 p. m., after the volunteers had been under emotional tension for 6 hours.

The lack of correlation of steroid values with age is contrary to the findings of previously published studies on hospitalized groups. The studies on sedimentation rates and steroid values will be continued and coordinated. It will be necessary to obtain electrophoretic serum protein studies on a group with abnormal sedimentation rates plus adrenal steroids and, possibly, C-reactive protein studies.

Physical Findings

General physique is the most important determinant of general employability as distinct from fitness to engage in a specific occupation. The accompanying frequency distribution chart (fig. 1) illustrates this aspect of fitness for continued employment. An artificial cutoff (except for one case) in the number of persons over 65 years of age is included in this early stage of the survey. This cutoff will disappear as we re-examine our increasingly large sample at intervals of 2½ years.

In the top half of the chart, which shows the results of examinations, there is no slope to the mean or median lines. There is no evidence, therefore, of correlation between age and general physique in the limited sample aged 50-64 years.

toration in intelligence and organic brain damage. Only five cases had clinically perceptible brain damage and, therefore, organic deterioration. In 122 cases, beginnings of functional deterioration were determined by psychometric or clinical methods of observation, or both.

The average I.Q.'s of the 148 subjects on whom complete Wechsler-Bellevue tests were done are shown in table 1.

Manual ability has not deteriorated to the expected extent in these subjects. The age credits for this need revision.

There was an inverse relationship between the deterioration quotient and intelligence. Exactly one-half of the subjects showed the expected deterioration; 32 percent showed more deterioration than expected and 18 percent, less than expected.

The deterioration quotient as presently calculated is only of qualitative value. The "hold-don't hold" formula needs revision. Some of the "hold" items for example, require sensory acuity of a degree which is not usual for this age group.

Rigidity is an outstanding characteristic of these subjects, especially when thinking at an abstract level is required. Our volunteers had difficulty in tasks requiring concentration or a focus of attention. In some, considerable tension was generated by such requirements.

We would prefer to use efficiency quotients as a standard instead of intelligence quotients, but we are not sufficiently sure of the true meaning of the efficiency quotient.

Some Aspects of Personality

The distribution pattern of the personality types of our volunteers as recorded at the weekly meeting is shown in figure 3. The predicted rate of change shown in the bottom half of the chart is based on clinical knowledge of the usual rate of change in known syndromes as seen by experienced observers. Ages have been offset by 5 years to allow direct comparison of the slope of the means.

The difference between P1 and P2 in the top half of figure 3 is undoubtedly due to the smallness of the sample. Otherwise there is no visible slope to the mean or median line. If our predictions are valid, there is a slope downward and to the right in the half of the chart which represents our 5-year predictions. To test the importance of this trend, the standard deviations of P3 and P4 were calculated. The CR difference calculated from these is 1.75, which is at the 5 percent level of confidence.

It is safe to say, therefore, that there is no significant deterioration in personality in this group in the age range 49-59 years. If our predictions are valid, there will probably be deterioration in personality in the sample at a

vious experience of the authors. Intrappolation of results was also possible because the procedures had been tested on younger and fitter, as well as on older, more deteriorated groups before beginning this survey.

In both upper and lower halves of the chart, both median and mean lines curve sharply to the bottom right. The standard deviation of M4 in the top half of the sample is noted to be only 8.7. This is probably significant.

In terms of M4, the change between M3 and M5 is 11.4.

In this sample, intelligence probably begins to deteriorate at between 50 and 65 years of age. If our predictions are valid, deterioration will continue at approximately the same rate in the following 5 years. (The slope of the "examined" and the "predicted" mean lines are the same.)

There is little or no correlation between de-

Figure 2. Mentality of 150 employees of retirement age. Upper half, results of examination; lower half, estimated probable changes.

Courtesy of Sunnybrook Hospital, Department of Veterans Affairs, Canada.

M1 Intelligence of a superior order capable of understanding and undertaking long-range planning, organization of details, integration of different aspects of a plan; flexibility and individual initiative. I.Q. 140-129.

M2 Intelligence sufficient to plan and carry out work accurately without supervision. Knowledge of job's relationship in broader setting and ability to assume and execute responsibility under supervision. Capable of working accurately under pressure. I.Q. 128-110.

M3 Intelligence sufficient to work accurately under normal supervision and normal conditions. Capable of learning new skills as required. Skilled labor. Normal intelligence. I.Q. 109-91.

M4 Intelligence sufficient for simple routine tasks under supervision, can learn related tasks. Semi-skilled and labor. Dull normal intelligence. I.Q. 90-80.

M5 Requires extra supervision due to slowness and failure to understand. Unskilled labor. High-grade defective. I.Q. 79-70.

M6 Requires almost constant supervision and direction at each stage of work. Learning ability poorly demonstrated. Constantly supervised labor. Moron. I.Q. 69-60.

M7 Unable to understand nature of job or remember steps in an operation. Unemployable in any capacity. Imbecile and idiot. I.Q. 59-0.

the psychologist, who uses tests such as the Rorschach which do not use direct questions. Fairly strong motives are discovered best by such techniques, especially if they are contrary to the principles of action of the integrated patient. Even negative information, such as gaps in work histories, are valuable clues to personality. The composite picture obtained can be translated into the jargon of any profession.

Our psychologist used two unstandardized tests of her own devising to assist in sorting out the personality patterns of this age group. They were an adjective list descriptive of optimistic and pessimistic mood states and a sentence completion test consisting of 60 phrases all beginning with "I" or "My." These have been useful with volunteers but, as practical instruments in an industrial situation, they are subject to evasion, although they would be useful in specific instances.

Our volunteers were very modest about their intellectual endowment; 74 percent specifically denied being clever. They were very free in admitting emotional upset; 53 percent claimed to be chronically tense and anxious. About one-third feel insecure, that they are slipping in their work, are growing more seclusive, and have a lowered frustration tolerance. The lack of structure of the sentence-completion test

threw them on their own resources and was too great a challenge for some, resulting in confusion, superficiality of response, or inability to respond.

The Rorschach test is an extremely useful tool for testing individuals in the older age groups. Unlike younger groups, the older person does not accept or enjoy the challenge of this test, and the lack of a defined structure produced confusion, anxiety, and self-doubt. The majority of the volunteers were unable to handle the intangible or the abstract. They were sure there had to be a "right way" to solve the test. In almost all the records, there was a hint of this superficiality and rigidity. In some, it was predominant. When the patterns were emotionally stimulating, there was actual withdrawal with overt tension.

Conclusions

1. We have developed methods of assessing older employees which, within 2-5 years, by deletion and rearrangement, can be made practical and economical for industry. By that time, the substitution of a disability retirement plan for a fixed-age retirement plan should be medically feasible and sound efficiencywise. The economics of such a plan need further

statistically significant rate in the group aged 65-70 years (1 man aged 70).

The personalities of our sample are a cross section of their age group. It must be emphasized that all these employees are earning their living and are therefore "normal." Any other criteria of normalcy are rather unrealistic in this far from perfect world.

To facilitate future study, the reaction pattern of each person was determined. The group was then subdivided according to predominant reaction (table 2). Such a subdivision is inevitably rough since the higher the personality

and intelligence rating, the more difficult it is to classify an individual. In 32 cases, the attempt was abandoned.

The dominant personality type of each volunteer was determined clinically. At the weekly conference of examiners, the personality of each person in the study is, of course, the subject of group discussion. Each examiner brings to the conference information of value. Some volunteers talk well to the doctor; others become expansive and confidential with a financial officer; others, whose basic desires are battened down under fairly secure hatches, disclose more to

Figure 3. Personality of 150 employees of retirement age. Upper half, results of examination; lower half, estimated probable changes.

P1 Personality sufficiently stable to work with others in supervisory or administrative capacity; capable of earning cooperation of co-workers and respect of his abilities. Flexibility in interpersonal relationships and understanding of problems of the job, loyalty to organization.

P2 Personality sufficiently stable to work well with others and willing to assume partial administrative or supervisory responsibilities if required. Capable of taking direction without rancor.

P3 Personality sufficiently stable to take constructive criticism or advice. Cooperation with others without need to be on the defensive. Self-reliant.

P4 Personality shows signs of doubting own ability, hesitancy, and "tentative" attitude. Requires encouragement and support. Capable of cooperation with others.

P5 Personality shows signs of cracking under pressure of work criticism or staff changes and moves. Manifest in withdrawal or agitation or both.

P6 Personality shows signs of poor or defensive interpersonal relationships with overt criticism of others and difficulty in work relationships.

P7 Personality chronically shows signs of tension, anxiety, or withdrawal sufficient to disrupt work efficiency and interpersonal relationships. Severe neurotic or prepsychotic.

Workshops and Seminars

Highlights of workshop sessions at the Ann Arbor conference are reported by representatives of the Public Health Service. In addition the chairman of the Committee on Aging reports the recommendations of two seminars on professional training.

The Geriatric Clinic

Personnel from a geriatric clinic in New York City and from another in Florida presented their respective programs as a basis for discussion. One presentation emphasized the role of the geriatric clinic in the hospital, and the other, the role of the clinic in the community.

Such demonstration programs serve as teaching centers in geriatrics. They furnish information on the problems of the aged for their communities and provide other communities with useful information about managing the special needs of the aged.

Experience in these clinics has taught that, though the initial steps of performing a thorough examination and working out the plan of individual medical care are time consuming, they greatly reduce the time spent in maintaining patient care.

Special consideration to the needs of the aged may be given in a comprehensive care clinic or in a geriatric clinic. In either place, someone whose competence and attitude is oriented toward care of the aged should direct and coordinate the program.

Many agencies and professional workers believe services to the aged should be complete. Cooperation of the many agencies concerned, with a major guiding influence, would permit

such complete services to be realized with economy.

—MARTHA BALL NAYLOR, R.N., B.S., M.P.H., *chief nursing consultant, Chronic Disease Program, Division of Special Health Services.*

Housing and Long-Term Care

Discussions on housing by a group of physicians, nurses, hospital administrators, housing experts, and representatives of nursing homes were vigorous and enlightening.

They agreed on the following points: Those who are ill require medical care and nursing home facilities. Low-cost housing is a pressing necessity for the well or almost well, with varying degrees of homemaking service. Coordination between agencies that provide medical, welfare, and recreational services to the aged should be improved. Housing for the aged should not lead to regimentation or decrease the individual's independence. The aged should not be segregated. Integration with young people in housing projects should be encouraged.

They agreed that community surveys were necessary to indicate community needs and resources. The survey data, objectives of the facilities, and requirements for major equipment and employees in each area will provide the architect with the information necessary to appropriate design and construction. "Form will follow function."

They agreed that housing or long-term care facilities for the aged should be located in pleasant surroundings and should be accessible to visitors and employees. The availability of utilities and public transportation is of prime importance. The physical plant should be of

study, as do the precise limits of its applicability.

2. Functional deterioration in mentality and personality antedate and overshadow organic deterioration. Rigidity and withdrawal particularly should be susceptible to preventive methods.

3. The increasing rigidity of the aging employee makes large retraining schemes in industry uneconomical, except where an absolute shortage of a skilled trade exists, and suggests that the routine retention of rigid senior executives is unwise.

DOCUMENTATION NOTE

Copies of the Gulhemp scales have been deposited as document No. 5063 with the American Documentation Institute, Photoduplication Service, Library of

Congress, Washington 25, D. C. A photoprint copy may be obtained by remitting \$2.50; a 35-mm microfilm copy by remitting \$1.75. Advance payment is required. Make checks or money orders payable to Chief, Photoduplication Service, Library of Congress. Copies of the scales may also be obtained from the author.

Still Going Places

Active Management of Disability in the Aged

16 mm., black and white, sound, 1,450 ft., 40 minutes. 1955.

Audience: All physicians, especially specialists in physical medicine and rehabilitation.

Available: Film Library, Pfizer Laboratories, 630 Flushing Avenue, Brooklyn 6, N. Y.

A medical documentary film, written and directed by George C. Stoney in collaboration with Frederic D. Zeman, M.D., and Leo Dobrin, M.D., of the Home for the Aged and Infirm Hebrews of New York, this film demonstrates practical ways in which chronically ill or acutely dis-

abled patients of advanced years can be helped to live useful, self-sufficient lives.

A wide range of examples is

shown, each underlining the basic principle of active management: "by promoting movement one preserves the ability to move."

paid up at age 65 and others which are non-cancelable and on which the company can raise the premium only if it does so for all policyholders of this class.

There was rather common agreement that arrangements are needed for funding the increased cost of health care for the aged over the individual's working life or of spreading the extra cost of health services for the retired among all active employees. Insurance company representatives felt that there was no problem about covering employees over age 65 who are still working or retired workers who are receiving pensions, and they believed means could be developed for including retired employees in a company's group insurance program. They felt that the problem of health insurance for low-income aged persons was but a special aspect of that for all persons who have incomes too low to enable them to purchase insurance.

Recommendations proposed at the concluding session of the workshop ranged all the way from having private carriers press forward with their vigorous efforts to provide health insurance coverage to the aged, to provision of hospitalization benefits as part of the Federal Old-Age and Survivors Insurance program.

—LOUIS S. REED, Ph.D., *health economist, Occupational Health Program, Division of Special Health Services.*

Implications for Nursing

Physicians laid the groundwork through discussions on the physiological and psychological age changes and on helping the older person be independent.

Three nurses spoke on the implications for nursing in helping the older person to independence. One described the rehabilitation program of the Visiting Nurse Association of Allegheny County in Pittsburgh and exhibited self-help devices which the association has available for loan. One emphasized the need to examine hospital practices, attitudes, and mores, stating her belief that in many instances these meet the needs of the hospital and its personnel rather than those of the patient. One briefly pointed out general implications for

nursing, relating them to the discussions on physical and mental health at the Federal-State Conference on Aging in Washington, D. C., June 5-7, 1956 (see page 1209).

—ESTHER KAUFMAN, R.N., B.S., *public health nursing consultant, Chronic Disease Program, Division of Special Health Services.*

New Careers in Gerontology

Preparing medical students and professional workers for dealing with the diseases and disabilities of old age was the subject of a seminar on geriatric medicine conducted by Dr. E. V. Cowdry, director of the Werle Cancer Clinic, Washington University Medical School, and a second seminar conducted by Clark Tibbitts, Department of Health, Education, and Welfare, at the Ann Arbor Conference on Aging.

Other professional occupations associated with gerontology include professors of social work and public health, educators, State officials, administrators of old-age homes, case-workers, vocational rehabilitation workers, and counselors.

The seminar on geriatric medicine included senior faculty representatives of 10 medical schools as well as the Veterans Administration and the Public Health Service. A spirited discussion quickly brought general agreement that departments of geriatrics would be unwelcome additions to medical schools. It was also agreed that the schools must focus increasing attention on the problems of the aged. Students need to develop a more wholesome attitude toward this group of complex patients. Research needs to be intensified.

Although it is recognized that the faculty of each medical school will make its own arrangements, a coordinator for aging is needed to act as a focal point for activities related to aging.

The coordinator could be in any medical school department although most often he would be in the department of internal medicine. He would head an interdepartmental committee concerned with incorporating appropriate material on aging into the curriculum content of each department. He would spark research and would serve as liaison officer with

sufficient size to be operated economically. The possibility of future expansion should be kept in mind. A homelike atmosphere should prevail. Safety features should be included. Dark and congested areas should be avoided.

Stalling and programing of facilities for oldsters will depend on the size, number, and extent of medical and allied services in the area. Additional allowances must be made for administrative and maintenance service.

It is evident that new money is required to pay for personal health services. Redistribution of existing expenditures will not be sufficient. Old-age and survivors insurance is one source of funds available to the aged. Voluntary insurance is popular with many, but there is need to expand present voluntary insurance to include major medical contracts, home nursing, convalescent home care, appliances, drugs, and so forth.

—DANIEL J. DALEY, M.D., *assistant chief, Division of Hospital and Medical Facilities.*

Criteria for Retirement

A review of different types of retirement plans led to the quest for suitable criteria for retirement.

Chronologic age as a criterion for retirement is considered unsound economically and socially, having no relation to the nature of the worker's job or to his ability to perform his work. A retirement age should be determined by the health and performance of a worker. Retirement should be related to capacity and ability to perform gainful work. The goal in each individual instance should be to maximize employability. There is no evidence to substantiate the allegation that it is difficult to administer selective retirement.

Much research is needed on physiological age and other debated criteria for retirement. The practice of preparing employees for retirement should be adopted more widely. In described examples of this practice, emphasis is placed on annual physical examinations, annual talks on retirement plans, and frequent review of attendance history, production, attitude toward job, and present and previous health records.

When review discloses deficiencies, part-time employment is suggested.

Aging workers need, among other things, training and retraining facilities, community placement services of adequate size and composition, and well-supported educational opportunities.

—WILLIAM M. GAFAFER, D.Sc., *technical adviser, Occupational Health Program, Division of Special Health Services.*

Financing Health Services

The problem of meeting the cost of medical care for the aged was considered so important a facet of their health care that one of the three general sessions of the conference was devoted to this topic.

A spokesman for the private insurance companies said that in due course private effort would meet the problem. The private companies have already developed new types of policies for the aged. He noted that employers were working toward providing health insurance benefits for retired workers.

A representative of the United Automobile Workers held that the greater health needs of the aged, combined with their low financial resources, made it impossible for private insurance companies to provide adequate coverage. The solution lay, he believed, in expanding old-age and survivors insurance to provide hospitalization benefits, and presumably later, medical benefits to retired workers.

The workshop sessions on insurance methods for meeting the medical costs of older people were largely concerned with the present activities and accomplishments of Blue Cross-Blue Shield, insurance companies, and cooperative health plans in providing health insurance coverage to the aged.

A representative of the Michigan Blue Cross plan described in detail his plan's provisions for carrying retired employees including arrangements whereby they are carried as members of the employee group, receiving the same benefits at the same costs as active employees. Representatives of the insurance companies told of individual health insurance policies they have developed, including policies which are

paid up at age 65 and others which are non-cancelable and on which the company can raise the premium only if it does so for all policyholders of this class.

There was rather common agreement that arrangements are needed for funding the increased cost of health care for the aged over the individual's working life or of spreading the extra cost of health services for the retired among all active employees. Insurance company representatives felt that there was no problem about covering employees over age 65 who are still working or retired workers who are receiving pensions, and they believed means could be developed for including retired employees in a company's group insurance program. They felt that the problem of health insurance for low-income aged persons was but a special aspect of that for all persons who have incomes too low to enable them to purchase insurance.

Recommendations proposed at the concluding session of the workshop ranged all the way from having private carriers press forward with their vigorous efforts to provide health insurance coverage to the aged, to provision of hospitalization benefits as part of the Federal Old-Age and Survivors Insurance program.

New Careers in Gerontology

Preparing medical students and professional workers for dealing with the diseases and disabilities of old age was the subject of a seminar on geriatric medicine conducted by Dr. E. V. Cowdry, director of the Werle Cancer Clinic, Washington University Medical School, and a second seminar conducted by Clark Tibbitts, Department of Health, Education, and Welfare, at the Ann Arbor Conference on Aging.

Other professional occupations associated with gerontology include professors of social work and public health, educators, State officials, administrators of old-age homes, case-workers, vocational rehabilitation workers, and counselors.

The seminar on geriatric medicine included senior faculty representatives of 10 medical schools as well as the Veterans Administration and the Public Health Service. A spirited discussion quickly brought general agreement that departments of geriatrics would be unwelcome additions to medical schools. It was also agreed that the schools must focus increasing attention on the problems of the aged. Students need to develop a more wholesome attitude toward this group of complex patients. Research needs to be intensified.

Although it is recognized that the faculty of each medical school will make its own arrangements, a coordinator for aging is needed to act as a focal point for activities related to aging.

The coordinator could be in any medical school department although most often he would be in the department of internal medicine. He would head an interdepartmental committee concerned with incorporating appropriate material on aging into the curriculum content of each department. He would spark research and would serve as liaison officer with

the general university. It is vital that he have full financial support and control of an adequate budget.

Graduate departments should be organized to train investigators and teachers in geriatric medicine, the seminar indicated. It was agreed that large numbers of geriatricians are not required for service programs since medical care of older people is the legitimate province of the internist and the general practitioner.

Although the second seminar was exploring a relatively uncharted field when it considered professional training for gerontology, it was able to reach several major conclusions.

For example, it was agreed that middle age and old age are identifiable periods of life, having characteristics that should be studied in all of the life science and social science courses given in secondary schools and in colleges and universities.

Equally general was the agreement that gerontology is a science in its own right and that all professional persons planning to work with older persons should have specialized training throughout their preparation in didactic instruction and fieldwork.

This seminar identified three principal occupational categories calling for specializing in work with older persons: the professional occupations such as social work or adult education, related occupations having some involvement with older persons, and generalists in aging.

The generalist was defined as an individual who has a broad knowledge of the characteristics, needs, and circumstances of aging and older people; understanding of aging as a social, cultural phenomenon; knowledge of community organization and resources; and skill in working with individuals and groups. His training should draw upon the biological, psychological, and social sciences at the graduate level.

Generalists are employed as community and State coordinators in aging, administrators of old-age homes, specialists in voluntary and governmental agencies, and executives of university programs. As awareness of the expanding field grows, the number of places open to generalists is expected to increase rapidly.

As to the administrative location of gerontol-

ogy training in a university, the seminar leaned toward establishment of a new department or institute that would offer core courses in gerontology combined with elective courses in related departments.

—CLARK TIBBITTS, *chairman, Committee on Aging, Department of Health, Education, and Welfare.*

Health Assessment of the Aged

Guidelines for health evaluation of aged patients were matched against experience in a wide variety of settings. These included clinical and group practice, special studies, retirement communities, and industrial health services as well as a public assistance program for periodic evaluation of nursing home residents, a geriatric clinic, and a rehabilitation program in a county home.

There was agreement that assessment of the aged person's health must be a total evaluation of his physical, psychological, and social state as well as his potential response to restorative services. Each discipline described not only its function in evaluation of current status but also what it could contribute to restorative services. Evaluation was seen as a continuing process rather than as a single-shot verdict.

There also was agreement that we have few controls against which to evaluate the physical, emotional, and social status of aged patients.

Throughout the discussion, the lack of standards or adequate tests for the aged was a recurrent theme. Hypertension in the aged was described as a relatively benign disease, usually overtreated. Internists commented that many symptoms in aged patients do not have the same significance they would have for the young. They described marked discrepancies between findings at autopsy and the functioning ability of a person immediately before death: Many functioned well despite severe physical handicaps; others functioned poorly although their physical condition appeared to be relatively sound.

Psychologists commented that tests which have been developed for adolescents and young adults do not apply to the aged. For example, a psychiatrist described an engineering pro-

fessor approaching retirement who made a poor score on blocks and numbers tests but who was brilliant at explaining abstruse differential equations to graduate students. He had passed so far beyond elementary skills that he no longer had use for them. Another psychiatrist commented that dreams of the aged have quite different interpretations from those of the young.

Social scientists described changes in responsibilities, roles in the family and community, and expectations of the aged. Social workers described differences to be considered in offering service to the aged, for example, the possible need for shorter, more frequent, and perhaps more continuous contacts by whoever is offering service.

A point of complete agreement was the importance of considering patients' functional ability and potential, with emphasis not on what had been lost but on what remains or can be restored. Also of prime importance are a hopeful attitude on the part of staff working with the aged and the factor of hope in the aged person himself.

—ELEANOR MORRIS, M.S.W., *medical social consultant, Heart Disease Control Program.*

Nutrition and Health

Dietary habits of aged persons and their food needs were reviewed by a physician and by research and public health nutritionists. How to plan menus that meet nutritional needs was discussed and demonstrated by the use of illustrative material.

The points brought out were not new or startling. Rather, the discussion leaders cited studies and experiences which emphasized the following accepted nutrition facts.

The importance of individual variations with respect to nutrient needs, total calories, and so forth must be kept in mind always. Thus, what is a maintenance diet for Mrs. Jones may be excessive in calories for Mrs. Smith or deficient in nutrients for Miss Brown.

The aged person needs protein of high quality daily, preferably some at each meal. The National Research Council's recommended protein allowance of 65 grams daily for men aged

65 was seen by some speakers as the low limit of desirable protein intake for both men and women.

The utilization of protein is related to the total calorie intake. Studies have shown that aged women on self-selected diets were in nitrogen equilibrium only when they were consuming 1,600 to 1,800 calories a day.

Since physical activity plays an important part in the body's ability to utilize foodstuffs, aged persons should be encouraged to maintain a level of activity compatible with their physical ability.

Total calorie needs decrease for each person as his body ages. Nutrient needs (for vitamins, minerals, protein) do not seem to decline and may be increased. To maintain good nutrition without increasing body weight, the aged individual must select food with care. Regular meals probably help in attaining this objective.

Although eating a variety of foodstuffs and choosing foods from the basic seven may be the easiest way of assuring an adequate nutritive intake, diets that are fairly monotonous may still be nutritionally balanced, depending on the foods eaten, the amounts consumed, the preparation methods. A survey in one State institution bears out this point.

—DOROTHY M. YOULAND, M.S., *nutrition consultant, Chronic Disease Program, Division of Special Health Services.*

Mental Illness Among the Aging

Two meetings were devoted to mental illness in the aged. The first discussed present-day State, county, or city mental institutions, which are recognized as lacking in facilities for the proper treatment of both acute and subacute psychosis among the aged.

A professor of psychiatry advocated the establishment of psychiatric services for the aged at nursing homes and other facilities where psychiatric care could be given on a part-time or full-time basis. He also advocated the building of public institutions for the care of the aged that would provide them with appropriate psychiatric services.

The second meeting was devoted to mental illness among the aged in the family setting. It was agreed that when acute and subacute mental illness was properly treated, prognosis for the aged was as good as for young patients. It was agreed further that many mentally ill individuals could be handled best either at home full time, if given proper outpatient psychiatric treatment, or at home part time and the

rest of the time in a mental institution or psychiatric hospital. Much emphasis was given to the need for part-time institutional care for many of the aged who have mental illness that is not completely incapacitating.

—SEWARD E. MILLER, M.D., former chief, Division of Special Health Services and presently director, Institute of Industrial Health, University of Michigan.

Reading List on Aging

Two general bibliographies on aging have been issued since 1954: *Selected References on Aging*; *An Annotated Bibliography*, 1955, and *Publications on Aging*; *Selected Reports of Federal Agencies*, 1956. The former was compiled for the Committee on Aging by the Library of the Department of Health, Education, and Welfare, and the latter by the Federal Council on Aging. These bibliographies may be obtained from the Superintendent of Documents, U. S. Government Printing Office, for 30 cents and 15 cents, respectively.

Both bibliographies are annotated and classified and include not only references to books and pamphlets but also to articles appearing in periodicals.

"*Selected References on Aging*" includes some 500 items compiled from current literature in the field. They are arranged within three broad interest categories: social aspects; economic and employment aspects; and the aging process, with respect to health and medical care. Other sections include reports on conferences and State commissions, conference and group discussion methods, periodicals, community helps, and personal adjustment. There is an author index.

"*Publications on Aging*" includes some 78 reports by or for various Government agencies. Among these items are bibliographies and exhibits, motion pictures, recordings, and scripts.

Although there is some duplication in the two bibliographies, together

they afford a fairly comprehensive coverage of the literature.

The following references, not contained in these bibliographies, also may be helpful.

Brewster, A. W., and McCamman, D.: Health costs of the aged. U. S. Social Security Administration Division of Research and Statistics, Report No. 20. Washington, D. C., U. S. Government Printing Office, 1956, 126 pp. Price 65 cents.

Toward Improved Health for the Aging

AT THE Federal-State Conference on Aging in Washington, D. C., June 5-7, 1956, more than 250 State and Federal officials met to study the field of aging and to work toward practical programs. Following panel discussions six groups drafted recommendations with respect to Federal and State responsibilities, organization, and techniques for improving the health and welfare of the aged. The panel discussions on health and rehabilitation and the recommendations on physical and mental health are summarized here. Major recommendations of each working group were reported in the June 25, 1956, bulletin of the Social Legislation Information Service, Washington 6, D. C. Proceedings of the conference will be available from Louis H. Ravin, secretary, Federal Council on Aging, Department of Health, Education, and Welfare, Washington 25, D. C.

DISCUSSIONS

Federal-State-Local Responsibilities

The Federal Government has a vital interest in the aging problem, Dr. Lowell T. Coggeshall, special assistant for health and medical affairs to the Secretary of Health, Education, and Welfare, said in pointing to the need for public and private agencies to work together to find realistic solutions. Excellent work is being done by the voluntary agencies, and the Government should support, not supplant, such work, he said.

Coggeshall urged development of active programs of restorative services in every community to increase the functioning of the sick and disabled older person to his highest attainable level while reducing the costs of his care. Day centers and day hospitals and physical or

mental therapy will tend to lessen the demand for hospital beds and bring treatment to more patients.

Research is as much a State as a Federal responsibility, Dr. Coggeshall declared. It should be carried out by the operating agencies of the State as well as by the State's medical schools. Stimulation of programs of home care, training of more practical nurses, and proper use of existing facilities will all help to reduce cost of care.

Living arrangements which permit activity, participation, and productivity will prevent a considerable degree of mental deterioration, he noted. Because almost all older people suffer periods of depression, particular care must be taken to see that these people are not committed to State hospitals during these periods. The use of intensive therapy at State hospitals has brought about a significant increase in the discharge rate. Such treatment has a higher cost per day, but its total cost is much less since the patient remains in the hospital a relatively shorter time.

Coggeshall listed four responsibilities of the official health agency: public education, stimulation or provision of services, training of adequate numbers of health personnel, and research.

The Administration's philosophy, he said, is that maximum freedom must be guaranteed to our senior citizens. The emphasis is on encouraging individual initiative within our free society, and thus enriching life for every individual.

The aging problem is primarily a community responsibility, according to Dr. Henry Mulholland, chairman, Committee on Aging, American Medical Association. He emphasized the need for careful community planning

and for coordination of various agencies and facilities. He noted that, while such institutions as nursing homes, homes for the aged, and rehabilitation centers are all necessary, "they should not make us forget that the home itself is often where the older person is happiest, when it is possible for him to remain there."

Neglected Health Problems

Dr. Lester Breslow, chief, bureau of chronic disease, California Department of Health, said that all too frequently aged patients in institutions are there not because of their disease but because of neglect of the disease. With modern methods, persons suffering a stroke need not remain bedridden the rest of their lives.

Dr. Breslow mentioned the need for good nutrition in later years and said that such everyday necessities as eyeglasses, hearing aids, and dental care should not be overlooked. Early detection through multiphasic screening can often help prevent or delay diabetes, glaucoma, and cancer. He emphasized that "we should make sure that the money we spend for our older population is wisely spent, not for more drugs and more beds—mere custodial care—but for the newer diagnostic, rehabilitative, and other services which will truly advance the health of the aging."

Degenerative disease is now an obsolete term, Breslow said. Even arteriosclerosis and cancer can be helped, and we now believe these may be due to specific environmental factors rather than to inborn, constitutional causes.

In one study of nutrition in persons from 50 to 80 years of age, it was found that many were not getting vitamin C and other nutrients necessary to a well-balanced diet. A health and health services survey in Santa Cruz County highlighted need for eyeglasses, hearing aids, and dental care among the aged. One California county health officer organized a health checkup for every recipient as he was accepted for assistance, with a view to correcting or alleviating conditions needing attention. The public welfare budgets in most counties do not provide enough money to maintain adequate health standards for recipients.

Rehabilitation Services

"Restorative medicine," a term describing measures taken to improve the functions of people with disabilities resulting from illness that comes with aging, was discussed by Dr. Michael Dacso, director of geriatric rehabilitation, Goldwater Memorial Hospital. We must rehabilitate people to self-care without regard to their vocational goals, he said. We can expect higher dividends by investing more at the beginning through skilled workers and excellent services. How to get the young medical man acquainted with and interested in the problems of the aged and the chronically ill is a question we must answer.

Few rehabilitation services are available to the aged who are disabled, according to Dacso. The tendency is to do the most for the reemployable. Probably 70 to 80 percent of all the disabled could be cared for at home with proper medical direction and auxiliary help.

We should practice "anticipatory medicine" (Stieglitz' term); that is, we should anticipate complications which may arise with a particular illness and take steps to prevent such complications. Rehabilitation services are expensive, but economy measures in rehabilitation frequently turn out to be more expensive in the end. People who could have been directed toward partial or complete self-help at the beginning of their trouble are robbed of that opportunity as they lose more of their health or their initiative and self-reliance.

Common, garden-type depression or melancholia is the type of mental illness most frequently encountered among older persons. Metabolic disorders and senile dementia are other common troubles. But even many afflicted with senile dementia could be returned to their homes. A fact we must face is that many families do not want their aged members back after they have had institutional care. Probably between 60 and 70 percent of old people in mental hospitals could be returned to their homes, although not necessarily as self-supporting citizens.

Today the medical pendulum is swinging back from hospital care to home care, Dr. Jack Ewalt, Massachusetts commissioner of mental health, observed. He stressed the need for careful research on all phases of aging and de-

plored the use of such thoughtless generalizations as "all old people should retire" or "all old people should keep on working."

Cost of Care

E. A. Van Steenwyk, director of the Philadelphia Blue Cross, gave examples of the mounting costs of hospital care and explained the expense of carrying older persons on the insurance rolls. He added, however, that companies must continue coverage on policyholders as they grow older. Blue Cross continues to cover policyholders who are retired or aged or both, he pointed out, but no insurance firm can do this unless it has had subscribers long enough to build up a funding system big enough to cover the expense of the aged.

More use of public health nursing services could be made and would pay off. It is far more economical to keep the moderately ill or the chronically ill patient at home than to put him in a \$25- to \$30-a-day hospital bed, Van Steenwyk noted. He urged closer coordination of the various agencies concerned with the aging problem and "wise spending" of all money appropriated toward this end.

RECOMMENDATIONS

The working group on physical and mental health emphasized the need to intensify community education to increase understanding of the problems of the aged and to make known what facilities and services are available. The group agreed that each individual must do his best to maintain his own and his family's health. With the objective of helping people to help themselves, they made the following recommendations:

Maintenance and promotion of health. Health and health-related agencies and groups should take constructive action to maintain and promote the health of all persons through programs for early detection of disease, prevention of disease and its consequences, suitable care during illness, and restoration of physical and mental health. All facilities for the care of the aged, including foster care homes, nursing homes, specialized housing, hospitals, and reha-

bilitation centers, should be of high quality. They should provide for careful medical appraisal and social evaluation of each individual.

Treatment of the whole person. State and community agencies should fully accept the concept of treatment of the whole person, as opposed to a focus on a particular disease entity. Analysis of the health and welfare characteristics of the community should serve as the basis for coordinated services to lessen the effects of disease and to reduce stay in hospitals and institutions.

Homelike conditions. Institutions and hospitals should not be regarded as the normal habitat of human beings. It is deemed of great benefit to the individual, the family, and the community to keep individuals in their own homes. If this is not possible, care should be provided in a situation approaching home conditions as closely as possible.

Participation in community life. States and communities are urged to encourage aging persons to participate in all phases of personal and community life. For example, financial incentives should be used to encourage nursing homes to keep patients mobile and to make full use of community services.

Community services. Community services for the aged should be provided to fill the needs of the individual fully but economically. Services should include homemaking aids, public health nursing, nursing homes, hospitals, case-finding activities, and rehabilitation. Transition of the patient between the simple, more economical services and the complex, more expensive ones must be easy.

Commitments to mental hospitals. Because of lack of suitable facilities at the local level for care of older persons, many are being needlessly committed to State mental hospitals. Medical care at the local level that includes screening, diagnosis, and early treatment can prevent many unnecessary commitments and certain other psychiatric casualties.

Nursing homes. To improve the quality and quantity of medical and nursing care in nursing homes, general hospitals and nursing homes are urged to work together in developing effective working relationships. Wherever possible, nursing homes should be administratively affiliated with general hospitals.

Food and drug protection. Official agencies should extend research, evaluation, and regulations concerning special foods, drugs, cosmetics, and various devices which are especially appealing to aging persons and which may be harmful to them.

Research and demonstrations. Federal, State, and private agencies should provide grant-in-aid funds for demonstrations of community health services for the aged and for both basic and applied research in gerontology.

Teaching of basic concepts. Funds should be provided to develop programs in universities for teaching students in health and related fields the basic concepts essential to the care and understanding of the aged. The need for focusing attention on the problems of the health of the aged can best be met by the appointment of a coordinator.

Alleviation of personnel shortages. To alleviate acute shortages of trained personnel in health, hospital, and related facilities, it is recommended that refresher training programs be expanded or initiated to develop community personnel resources; that action be taken to expand and improve acceptable professional training schools and facilities; that the possibilities of short courses for training personnel to aid professional staff be studied; and that recruitment programs be stepped up to permit maximum use of all existing and future training facilities and services.

Coordinating and advisory groups. Each State and each community should develop an effective, broadly representative organization to study and make known the problems and needs of the aging population and to suggest, support, and coordinate suitable and meaningful activities within existing agencies to meet these needs. All official health, welfare, rehabilitation, edu-

cation, and recreation agencies should be represented in this organization. In addition, there should be a citizens advisory group to provide liaison between this organization and the general population. This group should include representatives from interested professional societies and voluntary agencies.

Retirement. Retirement based on attainment of a certain chronological age results in some employees remaining on the job beyond the time when they are productive while others are retired who still have years of productive life ahead. Government and industry should be encouraged to expand and extend their health evaluation programs with the objective of determining more accurately the proper time for retiring individual employees.

Health insurance. Health insurance and other programs for financing medical care should permit flexibility in the use of treatment facilities and should facilitate transfer of patients among hospitals, nursing homes, and their own homes. Extension of voluntary health insurance coverage to the aged and arrangements for continuing health insurance after retirement, with benefits adapted to the increased health needs of older persons, should be encouraged. The utilization of health insurance plans should be considered in providing medical and hospital care to the aged public assistance recipient.

The chairman of the working group on physical and mental health was Dr. S. D. Pomrinse, chief, Health of the Aged, Division of Special Health Services, Public Health Service. Dr. C. J. Ruilmann, Tennessee commissioner of mental health, and Steven Horvath, professor of physiology and acting director of the Institute of Gerontology, State University of Iowa, were group leaders.

Rural Health Survey of Men Over Forty

By JOHN PEMBERTON, M.D., and KENNETH I. E. MACLEOD, M.D., M.P.H.

APPLICATION of preventive medicine to the later years of life is gaining attention from public health agencies. This is partly due to the remarkable decline in the mortality of children and young adults, which has brought the problems of morbidity and mortality in middle life into prominence, and partly to the failure of therapy in preventing the alarming rise in the death rates from certain diseases, such as coronary thrombosis and cancer of the lung, which bear most heavily on men in middle and later life.

A survey in 1955 was designed to find out something about the state of health, especially of the heart and lungs, of a group of men over the age of 40 who were living in a rural community. The study population, living or working in 6 of 16 towns of the Nashoba Health District in Massachusetts, was composed of all the men in the chosen age group who wished to be examined.

Altogether, 642 men came for examination. From many occupational classes, they included

physicians, bankers, priests, farmers, school teachers, clerks, and industrial workers of various grades of skill. The factories in which these men worked were small, long-established concerns situated in rural townships ranging from 500 to 4,000 in population. The plants included a tannery, two paper mills, a cordage factory, a cutlery works, and a plant manufacturing elastic underwear.

The participation rate from the factories was high. From information about the number in the eligible age group in two factories, where this point was checked, it was found that 47 out of 54 had come from one factory and 50 out of 52 from the other. There is, therefore, reason to believe that the sample was representative. Of course, those who were unable to come because of sickness or disability were necessarily excluded.

Participation was encouraged by vigorous preliminary publicity organized by a women's committee, utilizing press and radio, and the response was almost overwhelming.

The survey lasted for 3 weeks. In addition to daily sessions, several evenings were devoted to examinations for the convenience of the industrial workers.

Examination Procedures

A public health nurse recorded each patient's history of past illnesses, occupation, residence, and habits of tobacco smoking. The subject was weighed in indoor clothes and his height measured with his shoes on. Subsequently, 3 pounds was subtracted from the weight and three-fourths of an inch from the height.

Dr. Pemberton is a senior lecturer in social and industrial medicine in the University of Sheffield, England. From 1954 to 1955 he was a Rockefeller traveling fellow in medicine. Dr. Macleod is commissioner of public health in Worcester, Mass., and instructor in public health practice in the Harvard School of Public Health. He was formerly medical director for the Nashoba Associated Boards of Health, Ayer, Mass.

The assistance of the American Cancer Society made the survey possible.

A full-sized standard chest X-ray was taken. The Massachusetts Department of Public Health provided the chest X-ray machine and radiographers, and Dr. Marrian W. Perry of the State health department read the films. Helping organize the project were members of the Nashoba Health District Chest Survey Committee.

After the films were taken, each man was examined by one of the physicians with special reference to pulmonary disease. This examination included a respiratory function test, the 1-second timed vital capacity, to help detect emphysema (1). This test measures the vital capacity and also the proportion of the vital capacity which can be expired during the first second of a forcible expiration following a maximum inspiration. Finally, the subject was examined by the other physician with special attention to the cardiac system. This examination included measurement of the blood pressure with the subject in a sitting posture after a 5-minute rest. Whenever an abnormality requiring treatment was discovered, the subject was advised to see his private physician, to whom a report was sent.

The record sheets were designed to facilitate statistical analysis. The data were coded, transcribed, and punched on cards. Of the 642 records, 42 were incomplete, usually because the subject had failed to enter one examination room in his tour and had not been missed until after he had gone home. Thus, 600 completed records were available for analysis.

In selecting the data for presentation, we

have confined ourselves mainly to those conditions which were common, and we examined their prevalence in relation to certain identifiable characteristics such as age, weight, occupational class, and smoking habits.

General Characteristics

A wide range of ages were represented, but the sample consisted mainly of the middle-aged (table 1). About 85 percent were between the ages of 40 and 65. Five men were under the age selected for study.

There were no nonwhite men in the sample. Eighty-five percent were born in the United States, 6 percent in Canada, and 9 percent in Europe.

Six occupational classes were represented, with semiskilled and skilled workers predominating. Only 5 percent of the men had retired (table 2).

The great majority of the sample had always, or nearly always, lived in rural neighborhoods: 79.2 percent had spent less than one-tenth of their lives in cities of 100,000 population or more.

Tobacco Smoking

Table 3 shows the smoking habits of the sample for two age groups and for all ages. Of the lot, 28.8 percent were either nonsmokers or ex-smokers. Heavy cigarette smokers, defined as those smoking 20 or more cigarettes a day, were 38.3 percent of the total. The older men smoked less than the younger. A higher pro-

portion of those aged 55 or over had never smoked or had given up smoking, and the percentage of heavy cigarette smokers in the older group was only half that in the younger group. More older than younger men limited their smoking to a pipe or cigars.

The 89 ex-smokers were asked when they had abandoned the habit and for what reasons. There was evidence that the rate of giving up smoking had increased in recent years. More than a third of the ex-smokers had given up the habit during the 4 years immediately preceding the survey. Of the 55 who gave a reason for quitting, 18 said they did so to try to get rid of a cough, 10 stopped on medical advice, 2 quit after a surgical operation, and 24 gave non-medical reasons. Only one asserted that he stopped smoking because of publicity on cancer of the lung.

Pulmonary Conditions

There were 13 cases of pulmonary tuberculosis suspected on the basis of the full-sized chest films. Of these, only one was ultimately found to be active. Three were of doubtful activity.

Chest radiography disclosed two suspected cases of neoplasm. One man was found to have a benign tumor of the lungs, which was successfully excised. The other, at the time of writing, had failed to consult his physician.

The prevalence of chronic nontuberculous pulmonary disease in the different age groups appears in table 4. The definitions of the dis-

eases listed and a description of the diagnostic methods are published elsewhere (2).

Approximately three-fourths of each age group had no detectable pulmonary condition. Primary asthma was ascribed if there was a history of typical asthmatic attacks starting before the age of 25. This condition was not rare and was fairly evenly distributed in the age groups studied. The last three groups in the table represent increasing degrees of severity of chronic respiratory disease which, when fully developed, may be called chronic bronchitis, emphysema, and bronchial spasm. In its fully developed form it was uncommon under the age of 65.

Smokers' cough was the term applied to cough symptoms in those men who were heavy smokers if the answer to the first of the following questions or to any four of the others was "yes" and if no other cause for the cough was found:

- Does the cough go if you give up smoking?
- Does the cough get less if you give up smoking?
- Do you think the cough is due to smoking?
- Is it a dry cough?
- Is the cough the same in the winter and the summer?
- Is it largely confined to the first hour after rising?
- Is the cough largely associated with the first cigarette?

The prevalence of smokers' cough diminished with advancing age. This may be related to the smaller proportion of heavy cigarette smokers in the older age groups (table 3).

Table 3. Tobacco smoking habits in study group, by age

Age	Total	Never smoked		Ex-smokers		Cigarettes per day										Pipe or cigar only or both		Unre-corded	
						5 or less		About 10		About 20		About 30		40 or more

The relationship between cigarette smoking and chronic respiratory disease, excluding the 72 men with smokers' cough, appears in table 5. The frequency of chronic nontuberculous respiratory disease increased consistently through the various grades of smoking, from 4.8 percent in the nonsmokers to 29.4 percent in the heavy cigarette smokers. (The χ^2 test showed that this association of chronic nontuberculous respiratory disease with tobacco smoking was highly significant, $P > 0.001$).

Respiratory Function

There was an interesting association between tobacco smoking and respiratory function as measured by the timed vital capacity test (table 6).

The incidence of abnormally low vital capacity was considerably lower in the lifelong nonsmokers than in the other groups. The differences, however, did not quite reach the conventional 5 percent level of statistical significance. To measure the relationship between the vital capacity measurements and tobacco smoking history, the man's vital capacity was expressed as a percentage of the value predicted for him by use of the formula of Baldwin Courmand, and Richards (3). More of the smokers had abnormally low vital capacities than the nonsmokers or ex-smokers; but, again the differences were not statistically significant.

It was found that 51 out of 233 heavy cigarette smokers gave a history of wheezing (21.9 percent) compared with 12 out of 171 nonsmokers or ex-smokers (7.0 percent). The

Total	84	100.0	89	100.0	88	100.0	97	100.0	170	100.0	528	100.0

difference between these percentages was statistically highly significant.

The occupational and residential histories failed to reveal that more than a few had ever been exposed to harmful dust in their work or to air polluted by urban industry. It is assumed, therefore, that these factors had no significant part in the etiology of chronic respiratory ailments.

Cardiac Conditions

Twenty-three of the men were under the care of a private physician because of known heart disease, usually coronary artery disease. An additional 10 reported that they had had a previous coronary thrombosis from which they had recovered. These 33 cases represented only the gross manifestations of cardiac disease. There were probably additional patients whose symptoms had not caused them to consult a physician.

Special questions were introduced soon after the start of the survey to detect the presence of angina pectoris. Altogether, 42 of 407 questioned (10.3 percent) gave a typical history of pectoral angina precipitated by effort.

The percentage of heavy cigarette smokers (20 or more a day) among those with angina pectoris was 40.5 percent, nearly the same as the percentage among those without angina, 41.6.

There was no significant difference in the distribution by occupational class among those with angina pectoris and those without. There was a significantly higher proportion with enlargement of the heart (diagnosed by the chest roentgenogram) in the subjects with angina

pectoris than in those without. And a greater proportion of those with angina pectoris had systolic blood pressures of 160 mm./Hg or more and diastolic blood pressures of 100 mm./Hg or more than in those without. The differences in this case, however, did not reach the conventional level of statistical significance.

Overweight

Overweight was assessed by reference to average values of weight for given ages and heights, based on recent tables of mean weights at different heights and ages (4). All those who, at a given height and age, exceeded the mean weight by 10 percent or more were termed overweight. This group was further subdivided into those who were 10-19 percent overweight and those who were 20 percent or more overweight (table 7). Of the 600 subjects, 24 percent were overweight. More than 1 out of 10 exceeded by 20 percent or more the mean weight for age and height. The highest prevalence of overweight was found in the years 55-64. The apparent fall after this age may be attributed to a tendency for people to lose weight after the age of 64 or to higher mortality rates among those who are overweight. The association of certain signs of ill health with overweight was scrutinized.

Systolic and diastolic hypertension, pitting edema of the ankles, and a low vital capacity were more common among the overweight persons than among those of normal weight. The differences in these rates, however, did not reach the conventional level of statistical significance. Angina pectoris was equally common in those

Table 6. Tobacco smoking and the 1-second timed vital capacity in study group

Timed vital capacity	Nonsmokers		Ex-smokers		Pipe or cigar only		Cigarettes per day				Total	
							Less than 20		More than 20			
	Number	Percent	Number	Percent	Number	Percent	Number	Percent	Number	Percent	Number	Percent

Total.....	84	100.0	89	100.0	91	100.0	103	100.0	233	100.0	600	100.0

who were overweight and in the remainder. There was no association between overweight and occupational classification. The percentage of overweight persons in classes I and II combined was 23.8; in class III, 25.3; and in classes V and VI, 25.3. There was a slightly lower percentage of overweight subjects among the heavy smokers.

High Blood Pressure

High blood pressure is often regarded as inimical to a long and healthy life, although

surveys of this type usually disclose a considerable number of symptomless individuals with high blood pressure readings, who appear to be in robust health and may indeed be of advanced age. Table 8 shows the distribution of systolic and diastolic pressures by age. The proportion with high systolic pressures (160 mm./Hg or over) increased steadily with advancing age. The proportion with diastolic blood pressures of 100 mm./Hg or more increased with advancing age until age 64 and then leveled off.

The analysis revealed no relationship between

high systolic or diastolic blood pressure and occupational class or between high blood pressure and heavy cigarette smoking.

Discussion

The survey was limited in scope. Its major emphasis was on the discovery of chronic pulmonary and cardiac disease in a sample of men residing in a rural area. They were not chronically exposed to the crowding and air of cities. They seemed reasonably prosperous, and, in the six factories we visited, the conditions of work appeared healthful.

On the whole, their health was favorable. There was little significant pulmonary tuberculosis. There were those with frank cardiac disease, as would be expected at these ages, and no doubt a further number with incipient cardiovascular conditions.

Chronic cough, if smokers' cough is included under this heading, was common. An attempt was made to distinguish chronic bronchitis cases in the group with coughs. When this was done, it appeared that approximately 10 percent of the whole sample had chronic bronchitis. In only 3 percent of the sample, however, did we find the fully developed syndrome of chronic bronchitis, emphysema, and bronchial spasm. Half of the 18 severe cases occurred in men over 65. Before this age, it was rare. The prevalence rate of chronic nontuberculous respiratory disease (excluding smokers' cough) was significantly and directly correlated with tobacco smoking. The relatively large proportion of smokers and ex-smokers with abnormally low 1-second timed vital capacities compared with lifelong non-smokers suggests a relationship between tobacco smoking and pulmonary function. Whitfield, Arnott, and Waterhouse (5) found evidence that tobacco smoking reduces the vital capacity and increases the ratio of residual air to total lung volume, and both Palmer (6) and Oswald and Medvei (7), in studies of large unselected population groups, found a direct relationship between the amount of cigarette smoking and the prevalence of chronic bronchitis.

The other most striking finding in this survey was the high prevalence of overweight. Life

insurance statistics have shown that overweight policyholders are more likely than those of normal weight to die of diabetes, diseases of the biliary tract, appendicitis, nephritis, cerebral hemorrhage, cirrhosis of the liver, heart disease, hernia, and intestinal obstruction (8). Among the overweight in this sample, there were higher prevalence rates of high blood pressure, pitting edema of the ankles, and low vital capacities, and there were fewer heavy cigarette smokers. None of these differences, however, reached the conventional level of statistical significance. There was no relationship between overweight and occupational class or between overweight and angina pectoris. Keys (9) has reported a similar lack of association between overweight and coronary artery disease.

The small sample we examined failed to show any significant impairment of health that might be attributed to a deficiency in diet, shelter, or working environment. On the other hand, it is possible that the heart, respiratory, and overweight conditions observed may be attributed in part to a contemporary mode of living. Relative affluence, associated with full employment at attractive wages, permits diets abounding in fats and of as many cigarettes as time permits. The ubiquitous automobile and other forms of power machinery materially reduce the need to burn fats by physical exertion. It may be suspected then that a mode of living no less than aging contributes to certain afflictions characteristic of middle and later life. Identification of such immediate, as well as earlier, sources of impairment to health is a new task for preventive medicine.

Summary

Among 600 middle-aged and elderly men living in a rural area of Massachusetts, chronic cough, including "smokers' cough," was found to be common. Excluding cases of smokers' cough, there was a direct and significant relationship between tobacco consumption and the prevalence of nontuberculous chronic respiratory disease.

Only one case of active pulmonary tuberculosis was discovered.

Heart disease was not uncommon, and 3.6 percent were seeing a physician for this condition.

There were in addition, 10 men who had recovered from a previous coronary thrombosis.

Overweight was common; 13 percent were 10-19 percent above their expected weight for height and age, and a further 11 percent were 20 percent or more overweight.

It is concluded that conditions of prosperity may favor the development of certain diseases as was the case in the past and that a study of this relationship constitutes an important field for preventive medicine.

Center for Aging Research

In recognition of the urgent need to solve the special health problems of an aging population—the number of citizens over age 65 is expected to surpass 18 million by 1970—the Public Health Service on October 30 created a Center for Aging Research in the National Institutes of Health.

The center will coordinate research activities in the institutes and will stimulate additional research into the mechanisms involved in aging. Dr. G. Halsey Hunt, former associate chief of the Bureau of Medical Services has been named to direct its activities.

The new center is part of the Public Health Service's accelerated activities in the field of aging. Dr. John W. Porterfield, Assistant Surgeon General, will direct and coordinate all of the Service's activities in this field.

The Public Health Service has long been concerned with the health problems of the aging. In State and local health departments, restorative services for the aged are being supported in part by the Bureau of State Services. The major research effort of the Service has been centered in the National Institutes of Health, which at present is expending about \$2 million in its own research activities and in grant support of projects directly related to aging.

The accelerated programs will encourage and support research institutions in bringing the full range of biological, psychological, and social sciences to bear on the problem of aging. Part of the support to be provided by the Service will be in the form of research grants that will assist universities, medical schools, and other research institutions in establishing research centers on aging.

Blindness Among the Aged

By NEDRA B. BELLOC, M.A.

VISUAL ACUITY may be likened to a spectrum, ranging from normal or perfect vision at one end to total blindness or absence of light perception at the other. In a discussion of the extent of "blindness" in the aged population, it is necessary to remember that we are dealing with an arbitrarily defined group that includes only those with severe visual loss. The most widely accepted definition of "economic blindness" is that used in the administration of many programs of aid to the blind. Under this definition a person is blind if the vision of the better eye with best possible correction is 20/200 or less, or if he has a field defect in which the widest diameter of the visual field subtends an angular distance no greater than 20°. Persons in this group and many others with less loss of vision bear an inestimable burden in the social and occupational adjustments which their handicap requires of them.

How many aged persons are blind? How long have they been blind? What caused their blindness? These and other questions confronted the California State Department of Public Health when, in 1954, it received a grant from the W. K. Kellogg Foundation for a project in the prevention of blindness.

The Prevalence of Blindness

The literature reveals that most surveys of blind persons have been limited to recipients of

aid from one of the programs for the needy blind (1-9). Notable exceptions are New York and North Carolina, which have registers of blind persons (10-11).

The most widely used estimates of the prevalence of blindness are those of Hurlin (12) and are based on the assumptions that the rates will vary with age and race composition and with the public health standards of the States.

Data on the incidence of blindness are almost entirely lacking and, except where registers exist, must be inferred from prevalence figures (13).

During the year May 1954-April 1955, the California State Department of Public Health conducted a survey of a sample of about 10,000 households throughout the State. Data collected included population characteristics, illnesses, accidents, chronic conditions, and receipt of medical care. Interviewers handed respondents a list of chronic conditions which included blindness and asked, "Has anyone in the family had any of these conditions during the past 12 months?" The interviewers then read each condition aloud and paused for the respondent's reply.

Responses which indicated losses of vision more severe than those due to refractive errors were later coded as blindness, partial blindness, or vision impairment. The coding was done with the aim of producing an underestimate of blindness. Admittedly, some persons who were classified as blind may have better than 20/200 vision, but it is also likely that a larger number of those who were classified as partially blind are actually blind by the usual definition. It was apparent from the terminology of the responses, and from the comparisons which could

Mrs. Belloc is associate statistician with the prevention of blindness project, bureau of chronic diseases, California State Department of Public Health.

be made with available medical records, that to most lay people blindness means absence of light perception.

The prevalence rates shown in table 1 for the population 65 years of age or over are probably conservative estimates of the extent of vision problems.

Because of the size of the sample (2,600 persons aged 65 and over), these rates are subject to rather large sampling errors, and differences between income groups are not statistically significant. (The sampling error for the rate of 1.4 is ± 0.2 .)

In North Carolina, which has kept a careful register of blind persons for some years, 2.25 percent of the population aged 65 and over was blind according to the most recent report (11).

Another approach to the problem of determining the prevalence of blindness among the aged is to examine the portion of the population that receives public assistance. In California, recipients of aid to the blind normally receive \$10 more per month than they would receive under the old age assistance program. This differential probably encourages qualified persons to apply for aid to the blind rather than for old age assistance. It is known, however, that some blind persons are receiving old age assistance.

In California in December 1954, 271,347 persons were receiving old age security (14), and 8,025 persons aged 65 or older were receiving aid to the blind. Thus, 2.9 percent of the indigent aged were receiving the pension for the

blind. In counties known to have a liberal policy regarding applications for aid to the blind, this percentage was slightly higher. A blindness rate of approximately 3 percent in the indigent aged is not inconsistent with the rate of 2 percent shown for the aged population with incomes under \$2,000 per year in the California Health Survey. One would expect the highest blindness rate to be in the indigent population since blindness so often leads to dependency.

Obviously, then, blindness, with a prevalence rate of between 1.5 and 3.0 percent of the aged population, does not concern as many people as arthritis or arteriosclerotic heart disease. However, its prevalence is about the same as diabetes or neuritis in this segment of the population, according to data gathered by the California Health Survey, and its impact on those affected is undoubtedly greater.

In surveying the possible sources of data in California, the project found that the largest single group of records on blind adults is available in the California State Department of Social Welfare, which, together with the county welfare departments, administers aid to more than 12,000 needy and partially self-supporting blind persons. No analysis had been made of these records since 1945 when the department of social welfare published a study based on the 1941 caseload (4). In December 1954 the project surveyed the causes of blindness in this group, using as a source the reports of eye examinations made by physicians. Almost two-thirds of the recipients were 65 years of age or over. The study included 1,605 persons in this age group, representing a 20 percent sample of those who were 65 years of age or over.

Persons receiving aid to the blind may not be representative of all the blind since some causes may occur more frequently among those in higher economic groups, but data on the self-sufficient portion of the blind population are not available.

Age at Onset

Blindness had its onset before the age of 25 years for only about 6 percent of the group, and for an additional 5 percent it began between 25 and 44 (table 2). For about one-third the

trouble began in late middle life, and for more than half (54 percent) the condition started after the age of 65. The onset of blindness represents a different problem in each of these age groups, and its prevention will therefore have a different meaning. For those blinded in childhood or youth, the problem is one of training for a self-sufficient and productive life in a sighted world. Preventive activities here save society the expense of either this additional training or of supporting a dependent person for his lifetime. For those blinded in the early years of maturity, the problem is one of readjustment and rehabilitation, again with costly periods of training and possible dependency. Blindness which occurs after the period when occupational rehabilitation is feasible is likely to result in dependency, and its prevention means, of course, a prolonging of the productive years.

The Causes of Blindness

Tables 3 and 4 relate to the causes of blindness among this group of aged persons. Cataracts accounted for 35 percent of the blindness and glaucoma for another 16 percent. A large proportion of these cases are preventable or treatable. Next in importance were arteriosclerotic disease of the choroid and retina, with 11.3 percent, and retinal degeneration, with 7.5 percent (table 3).

General (systemic) diseases accounted for

SOURCE: Eye examination reports of the division for the blind in the California State Department of Social Welfare.

about half of the cases of known etiology, followed by infectious diseases and accidents (table 4). Diabetes was a more prevalent cause among the women than men, while accidents and syphilis accounted for a higher proportion of the blindness among the men.

Prevention

The etiology of the two major sources of blindness in older persons is unknown. Careful medical supervision and surgery at the appropriate time can, however, restore vision in a large portion of persons with cataract. Like-

wise, early detection and continued treatment of glaucoma can prevent loss of vision. For many in whom blindness is due to degenerative diseases, such as arteriosclerosis and diabetes (15), preventive activities must wait for further advances in medical knowledge (10). Fortunately, effective control measures are operating to reduce the toll of blindness caused by many of the infectious diseases such as syphilis, tuberculosis, trachoma, and measles. Ophthalmia neonatorum, which 50 years ago accounted for more than one-fourth of the blindness in school-age children, has, by the routine use of prophylactics at birth, been almost eliminated as a cause of blindness in infants (16). Adequate prenatal care, especially in the early months of pregnancy, may help to reduce the numbers of cases of congenital blindness. Educational work in the broad field of accident prevention will also help to prevent the loss of sight due to trauma.

Summary

Studies of the extent and causes of blindness in California indicate blindness in about 3 percent of the persons aged 65 and over who are receiving public assistance. More than half of these recipients of aid became blind after age 65 and about one-third in late middle life. Cataracts and glaucoma together accounted for more than half of the cases, followed by general diseases, infectious diseases, and accidents. Although the specific causes of cataracts and glaucoma are not known, much of the blindness from these conditions can be prevented by careful medical supervision and treatment. Preventive activities under way in the fields of infectious disease control and accidents are hopeful indicators of decreasing incidence of cases of blindness from these causes.

Glaucoma After Forty

With advancing years as physical activity becomes somewhat curtailed, our ability to read newspapers, books, and to observe television becomes increasingly important to our emotional well-being. Dr. Peter C. Kronfeld, speaking before the National Society for the Prevention of Blindness in Chicago March 28, 1956, indicated that in the population over 40 years of age chronic glaucoma occurs with a frequency of 1 to 2 percent. Unfortunately the silent character of this disease means that unless it is looked for specifically it may have progressed to such a point that it has caused irreparable damage. If it is detected during the first 2 years, the permanent visual damage is slight and a good therapeutic result can be anticipated.

Industrialists have been cognizant, through industrial safety programs, of the need for protecting the vision of those engaged in hazardous occupations, but some of these same industries have offered relatively little to their office and clerical personnel. Those with experience in this field tell me that when eye fatigue is minimized there is an actual increase in employee efficiency with improvement in equanimity. We have not done the many things that could be done to minimize eye fatigue.

—HAROLD M. GRANING, M. D., regional medical director with the Public Health Service, Region 5, Chicago, addressing the 1956 Middle States Health Conference.

Occurrence of Influenza July 1955 to June 1956

By DORLAND J. DAVIS, M.D., Dr.P.H.

DURING the period July 1, 1955, to June 30, 1956, the incidence of influenza was comparatively low in the United States. Although influenza A predominated, the small outbreaks of this type were sporadic and localized. There were, however, occasional sharp outbreaks in the east, midwest, and west during the late winter months of 1956. Clinically, the disease was mild, and no unusual mortality was associated with it. Influenza B was reported less frequently than in the previous 2 years. Influenza C was recognized principally in the late winter and early spring.

Of more than usual interest was an outbreak of specifically diagnosed influenza A during July 1955 in a penal institution at Hagerstown, Md. The cases were first noted July 18 and continued for 3 weeks. A total of 350 cases of respiratory illness occurred among 900 inmates, from a number of whom influenza A virus was recovered. No further outbreaks were recognized in the United States until the winter months, although serologic evidence of sporadic infections in military installations was found in November.

In England during December, influenza A infection was diagnosed among American school children at an Air Force base and also in scattered parts of the south of England as out-

Dr. Davis for the past 6 years has been executive secretary of the Influenza Information Center, WHO Influenza Study Program in the United States, National Institutes of Health, Bethesda, Md. He is associate director in charge of research, National Institute of Allergy and Infectious Diseases, Public Health Service. In the November 1955 issue of Public Health Reports, Dr. Davis discussed the occurrence of influenza for the period July 1954 to June 1955.

Reporting System

Current information on the occurrence of specifically diagnosed influenza and suspected outbreaks of influenza-like disease is published each week in the Communicable Disease Summary of the National Office of Vital Statistics, Public Health Service, and is distributed to health agencies in the United States and other countries. This is part of a worldwide effort sponsored by the World Health Organization to improve the reporting of influenza and to encourage exchange of newly isolated strains of influenza virus for investigational purposes.

In the United States, research laboratories, hospitals, and Federal and State agencies, including Army, Navy, and Air Force installations, report the observations to the Influenza Information Center of the WHO Influenza Study Program in the United States.

Dr. Carl C. Dauer, medical adviser of the Office of Vital Statistics, Public Health Service, is now executive secretary of the Influenza Information Center. The International Influenza Center for the Americas will continue under the direction of Dr. Keith E. Jensen at the Virus and Rickettsia Section, Laboratory Branch, Communicable Disease Center Activities, Montgomery, Ala.

breaks of relatively mild intensity. A few serologically recognized cases continued to occur during December in the United States.

In January, two sporadic cases of influenza A were diagnosed by virus isolation in the vicinity of Washington, D. C., but the incidence never attained unusual proportions.

During February, localized outbreaks of varying intensity were recognized in upstate New York; Pennsylvania; Cleveland, Ohio; and Illinois. Influenza A virus was recovered from some cases. In Herkimer and Fulton Counties, N. Y., the incidence of influenza was high enough to be reflected in a school absentee rate of 40 percent, but this rate did not obtain in other areas. California reported a number of serologically confirmed cases from the north central part of the State and the San Francisco area.

In March, specifically diagnosed influenza A continued to be recognized from the San Francisco area and also from the southern part of

Isolations of influenza virus and positive diagnostic serologic tests (any technique) reported by civilian and military laboratories participating, continental United States and Alaska

Month and year	Isolation of virus, type			Routine serologic tests, type		
	A	B	C	A	B	C
<i>1955</i>						
November-----	0	0	0	2	12	0
December-----	0	0	0	3	5	1
<i>1956</i>						
January-----	6	0	0	30	4	0
February-----	14	0	0	73	4	0
March-----	11	0	1	138	4	6
April-----	1	0	0	17	0	6
May-----	0	0	2	4	2	6
Total-----	32	0	3	267	31	19

California. However, it was not of the same order as that which occurred in 1953 or 1951 and clinically was not severe. Minnesota experienced a low incidence, most noticeable as a respiratory disease outbreak on a hospital ward. Influenza A virus was recovered in several instances. A localized outbreak of rather sharp intensity was also recognized in Hamilton, Mont., during this period. New York and other areas of eastern United States continued to report sporadic cases or small outbreaks.

California continued to report a few cases of influenza A in the month of April. In May, influenza C occurred sporadically at Great Lakes Naval Training Center, Ill., and 2 strains of virus were recovered from patients.

Of interest was the occurrence in Jamaica, B. W. I., of influenza A during December and January. Although the cases were described as moderately severe clinically, no unusual death rate was noted.

The mortality in the United States from all causes and from influenza and pneumonia did not reflect the occurrence of influenza A infec-

tion nor show any excess over that expected for winter months.

The strains of influenza A recovered from patients were antigenically similar to each other and to those recovered in the last several years in this country, including the A/FLW/1/52, A/Malaya/302/54, and A/Albany/2/55 strains. Influenza C virus strains were found to be similar to those previously isolated since 1950.

In contrast with the preceding year, no isolation of influenza B virus was reported to the Influenza Information Center, although there were a few reports of serologically diagnosed infection with this type.

The table shows that a total of 32 strains of influenza A virus and 3 strains of influenza C virus were reported as recovered in the United States during this time. By serologic means, 267 specific diagnoses of influenza A, 31 of influenza B, and 19 of influenza C were made. The distribution by months in this table has little significance because of the widespread sources and the small number of reports.

Roentgenographic findings support the conclusion that fluoridation of a municipal water supply results in a substantial reduction in dental caries among children.

Clinical and Roentgenographic Examinations for Dental Caries in Grand Rapids, Mich.

By RICHARD L. HAYES, D.D.S., H. BERTON McCAULEY, D.D.S., and FRANCIS A. ARNOLD, Jr., D.D.S.

DENTAL CARIES experience may be estimated by direct clinical observation, by roentgenography, or by a combination of the two methods. Direct observation is most convenient and is therefore most frequently employed, but the demonstration that bite-wing roentgenography is valuable for early detection of caries in the approximal surfaces of the teeth (1-7) has led to its use in several studies (8-14), including some in which it was the only method used. The combined technique, direct observation plus bite-wing roentgenography, consistently yields a higher estimate of caries prevalence than direct observation alone (7, 10-13); therefore, some observers

have suggested that X-rays are essential for dental surveys designed to determine the efficacy of caries control measures (8, 12, 15).

In Grand Rapids, Mich., a study to evaluate fluoridation of a municipal water supply as a caries control measure has been in progress since 1944. As part of this study, an investigation was undertaken to determine whether or not supplementing direct observation with roentgenographic examination would affect the conclusions based on direct observation alone. Caries experience was estimated separately by direct observation and by bite-wing roentgenography. The data were then combined in such manner that, if the conclusions were affected, it would be evident, and if not, the finding would be unequivocal. Hence, the method selected for combining the data gives the greater weight to the roentgenographic findings and presents the direct observation findings adversely. The roentgenograms were used also to estimate the depth of the carious lesions.

Methods

Each year since the start of fluoridation in Grand Rapids in January 1945, selected samples of school children have received direct observation examinations for dental caries. The

Dr. Hayes since 1952 has been with the Epidemiology and Biometry Branch, National Institute of Dental Research, National Institutes of Health, Public Health Service. Dr. McCauley, now director of the bureau of dental care, Baltimore City Health Department, Baltimore, Md., was engaged in epidemiological study of oral disease at the National Institutes of Health from 1945 to 1949. Dr. Arnold, a member of the Public Health Service's dental research staff since 1937, has been director of the National Institute of Dental Research since 1953.

examinations are performed by several dentists, using a mouth mirror, an explorer, and artificial illumination (16, 17).

In 1946, 1947, and 1953 (approximately 21, 33, and 105 months after fluoridation was begun), the annual dental examinations of children in the first, fourth, and eighth grades of four selected schools were supplemented by bite-wing X-rays. The X-ray examinations followed the regular examinations by a period varying from a few days to a month. Left and

right posterior bite-wing radiographs were made for every pupil. For each fourth-grade child (8-10 years of age), one anterior bite-wing X-ray was made to show the central incisor teeth; for each eighth-grade child (12-14 years of age), three anterior bite-wing X-rays were made to show the incisor and cuspid teeth. First-grade pupils (5-7 years of age) did not receive anterior bite-wing X-rays.

Roentgenographic interpretation was limited to the approximal surfaces of the deciduous

molar teeth of 5- to 7-year-old children, the central incisor and first permanent molar teeth of 8- to 10-year-old children, and the permanent teeth (excluding third molars) of 12- to 14-year-old children. Each set of roentgenograms received two independent readings. Each reading was made without reference to the clinical examination record and was recorded separately from the other.

The first step in recording the caries status of an approximal surface was to score it as

carious or noncarious. An approximal surface was scored as carious if the reader could detect a discontinuity of the enamel surface or any other sign of caries, such as an abnormal radiolucency at the dentino-enamel junction. These surfaces were designated as the maximum number of carious surfaces detectable by X-ray. Each carious surface was then further examined, and a separate notation was made for each one with signs of caries of the dentin. Surfaces with dentinal caries were designated

as the minimum number of carious surfaces demonstrable by X-ray. Radiolucencies contiguous to restorations were not recorded, but restorations were considered caries of both the enamel and the dentin.

After the completion of all X-ray interpretations, a master record of the roentgenographic findings was made for each child. This record, which contained the notations from each of the independent readings, was used in combining the radiographic and clinical findings. To give greater weight to the radiographic findings, an approximal surface was given a roentgenographic diagnosis of caries if it was scored as carious at either reading.

Two more records were then made for each

child: one for direct observation findings plus minimum X-ray findings; the other for direct observation findings plus maximum X-ray findings. Surfaces negative for caries according to direct observation but positive according to X-ray examination were added to the direct observation findings. Surfaces positive according to direct observation were considered carious at both levels of penetration, regardless of the X-ray findings.

Only children designated "continuous residents," that is, those who had consumed water from the Grand Rapids supply continually since birth and who had not been absent from that community longer than 3 months in any calendar year, were included in the study, although

others were examined. Of those who received X-ray examination in addition to the regular examination, 736 (312 in 1946 and 1947, and 424 in 1953) met the residence requirements. As there was no essential difference in the caries experience of the 167 radiographed in 1946 and the 145 in 1947, the data for these 2 years were combined.

The representativeness of the X-ray sample was determined by comparing the caries experience of the children in this sample, as deter-

mined by direct observation of the teeth, with that of their age peers in the entire sample of children examined in 1946-47 and 1953 (18). Between 1946-47 and 1953 both samples displayed substantial decreases in the number of def (decayed, indicated for extraction, or filled) deciduous teeth and in the number of DMF (decayed, missing, or filled) permanent teeth. Both samples yielded essentially the same results.

Support for Clinical Findings

Supplementation of the dental examinations with bite-wing X-rays did not change the basic observation that decreases in dental caries occurred among the Grand Rapids children between 1946-47 and 1953. The mean numbers of carious teeth were smaller in 1953 than in 1947 whether estimated by direct observation alone or by direct observation plus X-ray examination (table 1 and fig. 1). The same was

1953.....	1,692	266	59	207	1,426	3.5	12.2	84.3
		First permanent molars (ages 12-14)						
1946-47.....	696	355	240	115	341	34.5	16.5	49.0
1953.....	838	270	146	124	568	17.4	14.8	67.8

true for carious approximal surfaces (table 2 and fig. 2). Inasmuch as the changes in caries experience for children in this study as determined by direct observation alone were essentially the same as those for all the children in their age groups, it is likely that the rest of the first-, fourth-, and eighth-grade children would provide similar X-ray findings.

The reduction in caries between 1946-47 and 1953 was statistically significant, as can be seen by an inspection of the standard error terms (last column in tables 1 and 2). The reduction cannot be explained by differences in the age or sex distribution (table 3) or by variations in the number of teeth at risk (table 4) since these

were all essentially the same for the two periods. The between-method variation in the magnitude of the differences between the 1946-47 and 1953 caries rates might be attributed to chance.

The findings suggest, both numerically and proportionally, that there was little variation in the effectiveness of the clinical examinations between 1946-47 and 1953. The maximum X-ray increments for 12- to 14-year-old children were 3.60 DMF teeth per child in 1946-47 and 3.29 in 1953. If the mean number of teeth in eruption (table 4) is used as the denominator, X-rays revealed the first evidence of caries for 13 percent of the teeth in eruption in 1946-47

and for 12 percent in 1953. Selection of the denominator for these and other proportions is based on Hill's advice concerning numerators, denominators, and proper use of the risk factor (19).

New Information From X-Rays

The X-ray data revealed that most of the decrease in caries of the approximal surfaces occurred among the deeper lesions (those involving dentin) and that there was little or no change in the number of shallow lesions (those limited to the enamel). These findings are shown in table 5, where depth of lesion as de-

termined by X-ray is related to the number of approximal surfaces present. The denominators are the numbers of surfaces at risk; they are thus corrected for the slight variation in the number of teeth in eruption but not for any possible variation in time of eruption. Extracted teeth were excluded since there was no way of determining the caries experience of their approximal surfaces.

The difference between the 1946-47 and 1953 caries patterns with regard to depth of lesion is consistent with the hypothesis that fluoride retards the development of dental caries. A reasonable explanation for the data is that some enamel lesions did not progress to dentinal

¹ Minus indicates a decrease in 1953; plus, an increase.

lesions and that many enamel lesions did not occur or at least did not develop to a size detectable by practical methods. (Some enamel lesions might have been replaced by microscopic lesions of the type described by Burket (20); this study did not investigate these lesions). The nonappearance of the shallow lesions is also consistent with the hypothesis that fluoride actually prevents the inception of caries. The alternative hypothesis that fluoride selectively prevents caries of the dentin is not supported by these data, as this hypothesis would require decreases in dentinal caries to be balanced by increases in enamel caries.

Effect on DMF Studies

Bite-wing roentgenography produced less change in estimates of caries experience of teeth (DMF or def) than that of approximal surfaces (DF or df). This can be seen by comparing parallel radiographic increments of these scores in figures 1 and 2. The lower sensitivity of DMF estimates is related to the high susceptibility of children's teeth to occlusal caries (21), the relative ease of detecting occlusal lesions by direct observation (2), and the fact that a tooth is counted only once in arriving at a DMF score. Only radiographic evidence of caries in a tooth deemed to be free of caries on direct observation would add to a DMF score.

The methods selected for combining the direct observation and roentgenographic data did, in fact, present the direct observation findings adversely, as can be seen in figures 1 and 2. As shown in tables 6 and 7, different methods of using the two independent X-ray readings would have led to the same conclusions: that there was a substantial decrease in dental caries experience and that this decrease occurred primarily among the deeper lesions. The essential conclusion—that there was a substantial decrease in dental caries experience—was reached without the X-rays.

Summary

Bite-wing roentgenography was used to supplement the regular dental examinations of 736 continuous resident children of Grand Rapids,

Mich., in 1946-47 and 1953. Findings from direct observation indicated that the children in the X-ray sample were representative of their age peers in the entire sample of children examined in those years.

The roentgenograms were read for radiolucencies of dentin and for discontinuities of the enamel surface. For the primary purpose of testing the effect of X-ray findings on conclusions reached by direct observation alone, the X-rays were read twice and any surface scored as carious at either reading was added to the directly observed estimate of caries.

There were wide but consistent variations in total caries experience according to the three methods of estimation, but all estimates demonstrated a significant decrease in total caries experience between 1946-47 and 1953. The decrease in caries appeared to be greater for deeper lesions than for shallow lesions. This was demonstrated by analysis of roentgenographic data without reference to the regular dental examinations and was independent of the method used to combine the two X-ray readings. The decrease in the deeper lesions without a balancing increase in the shallow lesions suggests that fluoride retards the development of caries and that it also prevents the inception of caries.

From this study, we draw the following conclusions:

1. Roentgenographic findings support the clinical finding that fluoridation of a municipal water supply is an effective caries control measure.
2. Estimates of dental caries experience expressed as the number of decayed, missing, or filled teeth are less sensitive to modification by roentgenographic findings than are estimates of caries expressed as the number of decayed or filled approximal surfaces.

CONFERENCE REPORT

In the light of the needs for health services in the border region of the southwest, organized health officials there have recommended that official agencies underwrite a survey and evaluation of conditions as a guide to future action. At the same time, they have undertaken in an exemplary manner to help each other in dealing with responsibilities which respect no jurisdictional barriers. The following information, based on papers presented at the 14th annual meeting of the United States-Mexico Border Public Health Association, indicates both the challenges and achievements in this territory. The meeting was held April 13-16, 1956, jointly in California and Baja California in the border cities of Calexico and Mexicali.

MUTUAL AID

THE INTERNATIONAL BOUNDARY area between the United States and Mexico is unique, for here we have two cultures, representing striking contrasts in language, socioeconomic conditions, and technological development, confronting one another across a practically unguarded and, for the most part, sparsely settled border more than 2,000 miles in extent.

In order to foster understanding of public health needs and through mutual assistance to promote public and personal health along the United States-Mexico border, the United States-Mexico Border Public Health Association was organized in 1912 with the encouragement and assistance of the Pan American Sanitary Bureau. This official international health organization has continuously furnished our association with an executive secretary, who is also chief of the El Paso (Tex.) field office of the bureau.

During the past year two major accomplishments of the association were the bi-State meeting of California and Baja California, Mexico, and the Special Study Committee Conference recommendations on a proposed border evaluation study of health conditions and resources.

At the bi-State meeting of California and Baja California, more than 100 persons from local, State, and Federal health agencies, as well as social welfare and voluntary health agencies, participated in the deliberations.

This was the first bi-State meeting sponsored by our association.

The need for potable and adequate water supplies, safe sewage disposal, careful control and management of food supplies, safety factors in housing and employment, and in air pollution received special attention.

The lack of adequate sanitary facilities for

field workers in agriculture and the great need for careful study of working and living conditions of the migrant agricultural laborer and his family were emphasized.

The language barrier was mentioned as one of the problems of the maternal and child health program. It was suggested that incentive pay for bilingual health workers might help solve this difficulty.

An intensive program of investigation, education, and publicity was advocated in tuberculosis and venereal disease control.

The special study committee recommendations on a proposed border evaluation study of health conditions and resources were developed after much correspondence.

These recommendations have been submitted to the respective Federal departments of health and the Pan American Sanitary Bureau.

Other activities of interest to and stimulated by the association, either directly or indirectly, included the following:

Interchange of ideas and opinions regarding a border field training program and the possible establishment of a permanent field training center.

Tijuana, Baja California, and San Diego, Calif., both contributed to the cost of chlorination of the sewage effluent emptying into the Tijuana River as negotiations and discussions continue for a permanent solution of this pollution problem.

Meetings between Mexicali and Imperial County health officials were held with discussions referring to diarrhea, venereal disease, and the education and training of personnel.

Along the Arizona-Sonora border, in the area of Nogales, Naco, Agua Prieta, Bisbee, and Douglas, working relationships were established between the local health officials to control venereal disease.

El Paso, Tex., and Juarez, Chihuahua, joined in a mosquito survey in the two municipalities.

Personnel from Laredo, Tex., collaborated with the health officials of Nuevo Laredo, Tamaulipas, in carrying out a sanitation survey of that neighboring city.

From the address of George W. Marx, C.E., M.P.H., president of the association and director and chief engineer, bureau of sanitation and sanitary engineering, Arizona State Department of Health.

BORDER HEALTH CONDITIONS

The multiple complexities peculiar to public health services in semiarid lands, reviewed in the president's address, were dealt with separately by other speakers whose remarks here are grouped roughly in categories concerned especially with sewage disposal; the zoonoses; general sanitation, with special reference to the needs of migrant labor; health education; rehabilitation; and communicable diseases, in that order.

Sewage disposal presents unusual complexities in the southwest border region. Water for carriage and dilution usually is limited by an arid climate. Water used for sewage is used also in many places for irrigation. The irrigation ditches in dry seasons and the fields themselves, when they are occupied by armies of field hands, are fecal depositories. Contamination of the fields poses a possible threat to the

consumer of raw vegetables harvested there and increases the incidence of beef tapeworm, an expense to the cattle grower and a hazard to the health of consumers of raw or slightly cooked, uninspected beef.

Contamination by body wastes is a factor that enters also into the comments on the management of housing, both for permanent and transient residents; education to reduce infant mortality; and certain communicable diseases. Another pervasive theme in these comments, most evident with respect to health education and community organization, is the way difference in language and tradition affects health practices and attitudes. The last papers summarized below deal with microbial infections, which in many parts of the United States have ceased to be of major concern but which still persist as threats to the people of the border.

Irrigation With Sewage Impactical for Safety

The question of the use of sewage for irrigation was analyzed thoroughly by G. R. Herzik, Jr., chief engineer of the Texas State Health Department, represented by Frank J. Von Zuben, chief of general sanitation. Referring to the Willem Rudolfs (Rutgers) study, commissioned by the United States Army Quartermaster, he acknowledged that under careful control lands irrigated with sewage can produce vegetables acceptable for human consumption, but he held that such controls pose operating obstacles that "in practice are virtually insurmountable."

Beyond all controls on the farm, the Rutgers study concluded that "the only reliably effective method for decontamination, with respect to bacterial as well as helminthic organisms, is . . . pasteurization at 60° C. Not only are all the undesirable organisms killed, but the quality of the vegetable is not in-

jured," he said. But this precaution, too, seemed impractical for the homemaker. In June 1952, the Texas Board of Health prohibited sewage for irrigating food crops which might be consumed in the raw state.

Herzik spoke in favor of using treated sewage on fields used for animal feed or pasture or in connection with soil conservation work provided stream pollution is avoided. He does not believe wet or air-dried sewage sludge should be used to fertilize crops intended for human consumption.

Clean Water In Mexico

Against this background, P. J. Caballero, sanitary engineer, Office of Hydraulic Resources, Mexico, reviewed sewage disposal facilities in the Mexican watershed of the Rio Grande. Two international plants are in operation, and others are in construction. Most of the Mexican cities have sewers. No plants in the

watershed have treatment facilities, but their sewage is impounded before it reaches the Rio Grande. Lands irrigated with sewage are for the most part used to grow cotton, he said.

The most acute condition is created outside the Rio Grande Valley at Tijuana, Baja California. The Tijuana River carries sewage from that city through United States territory and contaminates California beaches.

At Mexicali, Baja California, and Calexico, Calif., treatment facilities in construction include 62 acres of oxidation lagoons with the possibility that the effluent may be used for irrigation or for washing salted land.

Tapeworm Hazard In Dry Lands

The animal stake in sewage disposal was described by Donald Miller, D.V.M., veterinarian in charge, Animal Disease Eradication and Animal Inspection and Quarant-

MUTUAL AID

THE INTERNATIONAL BOUNDARY area between the United States and Mexico is unique, for here we have two cultures, representing striking contrasts in language, socioeconomic conditions, and technological development, confronting one another across a practically unguarded and, for the most part, sparsely settled border more than 2,000 miles in extent.

In order to foster understanding of public health needs and through mutual assistance to promote public and personal health along the United States-Mexico border, the United States-Mexico Border Public Health Association was organized in 1942 with the encouragement and assistance of the Pan American Sanitary Bureau. This official international health organization has continuously furnished our association with an executive secretary, who is also chief of the El Paso (Tex.) field office of the bureau.

During the past year two major accomplishments of the association were the bi-State meeting of California and Baja California, Mexico, and the Special Study Committee Conference recommendations on a proposed border evaluation study of health conditions and resources.

At the bi-State meeting of California and Baja California, more than 100 persons from local, State, and Federal health agencies, as well as social welfare and voluntary health agencies, participated in the deliberations.

This was the first bi-State meeting sponsored by our association.

The need for potable and adequate water supplies, safe sewage disposal, careful control and management of food supplies, safety factors in housing and employment, and in air pollution received special attention.

The lack of adequate sanitary facilities for

field workers in agriculture and the great need for careful study of working and living conditions of the migrant agricultural laborer and his family were emphasized.

The language barrier was mentioned as one of the problems of the maternal and child health program. It was suggested that incentive pay for bilingual health workers might help solve this difficulty.

An intensive program of investigation, education, and publicity was advocated in tuberculosis and venereal disease control.

The special study committee recommendations on a proposed border evaluation study of health conditions and resources were developed after much correspondence.

These recommendations have been submitted to the respective Federal departments of health and the Pan American Sanitary Bureau.

Other activities of interest to and stimulated by the association, either directly or indirectly, included the following:

Interchange of ideas and opinions regarding a border field training program and the possible establishment of a permanent field training center.

Tijuana, Baja California, and San Diego, Calif., both contributed to the cost of chlorination of the sewage effluent emptying into the Tijuana River as negotiations and discussions continue for a permanent solution of this pollution problem.

Meetings between Mexicali and Imperial County health officials were held with discussions referring to diarrhea, venereal disease, and the education and training of personnel.

Along the Arizona-Sonora border, in the area of Nogales, Naco, Agua Prieta, Bisbee, and Douglas, working relationships were established between the local health officials to control venereal disease.

El Paso, Tex., and Juarez, Chihuahua, joined in a mosquito survey in the two municipalities.

Personnel from Laredo, Tex., collaborated with the health officials of Nuevo Laredo, Tamaulipas, in carrying out a sanitation survey of that neighboring city.

From the address of George W. Marx, C.E., M.P.H., president of the association and director and chief engineer, bureau of sanitation and sanitary engineering, Arizona State Department of Health.

Monterey County Health Department.

Many harvest workers, formerly stationed at sheds where they culled, packed, and iced vegetables trucked in bulk from the fields, now do their work with the use of cardboard containers and vacuum cooling at the picking site. This increase in the numbers of field workers has multiplied the need for toilets and lavatories, drinking water, and protection from excessive dust in the harvesting of fruit and vegetable crops.

After a survey of the needs, county health officials, under instructions from the State, proceeded to develop a pilot program of corrective measures, with the full cooperation of the Growers-Shippers Vegetable Association. The device most favored, after consideration of alternatives, was a mobile chemical toilet, with running water, a wash basin, paper towels, and soap, provided by the shipper for each harvesting crew. The units are housed in light steel, with an open metal floor, mounted on wheels for towing. A 50-gallon tank of water is fabricated into the top or back of the unit to supply the hand-washing basin. Drinking water will be supplied with paper cups or with portable fountains. The units will be inspected regularly. The next step is to appraise their value in use.

Border Population Moves and Grows

A general appraisal of sanitation needs in Mexico's border territory, by Joaquín Segura, sanitary engineer, Mexican Public Health Service, emphasized population growth, with a movement to urban centers. In recent years, several border cities have grown from a few hundred souls to tens of thousands. Progress in sanitation has been accompanied by a rapid decline in infant mortality in the border cities: from 266.4 per 1,000 in 1901 to 95.8 in 1950, with still some distance to go.

The health needs of the transient agricultural worker, or those who move to settle in rural areas north of the border, are complicated by a

strange environment, language difficulties, temporary housing, frequent change of locale, and by weather, altitude, and temperature conditions unfamiliar to the migrant. Such families also may be susceptible to pathogens which they encounter for the first time in a new environment.

Slum Clearance Project In Mexicali Area

A specific example of the management of a slum area in Mexicali, Baja California, was described by Enrique Ramirez del Toro, engineer in the Coordinated Health Services in the State of Baja California. As Mexicali achieved new growth, more than 10,000 people lived in the "New River" neighborhood, below sea level, subject to periodic floods, both from rains and sewers.

A flood in January 1955 brought the threat of an epidemic, which was met by the decision to evacuate the area. Families were quartered in private buildings and in schools, with food, clothing, and medicines provided by the government.

Health officials directed installation of cesspools, removal of domestic animals, installation of portable baths, immunization, and spraying of occupied buildings.

To provide permanent quarters for the families, the government awarded to each of 2,769 housewives a lot of 150 square meters in a neighborhood with a central park, planted with grass and flowers. Safety lanes are provided for pedestrians, and three zones are reserved for schools. The government also erected sample houses to stimulate private capital to invest in low-cost expandable homes, with hygienic facilities.

The former slum is now the site of the city's main sewer, known as the "Great Collector."

Cross-Border Projects Coast to Coast

Such joint concerns as the health of migrant families are the basis of cross-border health projects re-

viewed by Dr. David M. Cowgill, director of the Cameron and Hidalgo County Health Units, San Benito, Tex. These enterprises are in progress all along the border from the coast of California to the mouth of the Rio Grande. Specifically described were those of San Diego-Tijuana, Imperial County-Mexicali; El Paso-Juarez; Eagle Pass-Piedras Negras; Laredo-Nueva Laredo; and Cameron County-Matamoros area. Conspicuous among the joint projects were programs of sanitation, health education, vector control, water pollution control, prevention of venereal disease, and tuberculosis surveillance and treatment.

Farm Placement Prevents Infection

Health conditions of Mexican migrant workers were discussed in a review of the medical aspects of the farm placement program in charge of Dr. Harold D. Lyman, medical director, Public Health Service, El Paso, Tex.

There are four migratory stations south of the border. Migrants are examined at these stations by Mexican physicians and are vaccinated against smallpox by Mexican nurses. The examination selects those who are fit for hard labor and free from contagious or mental disease. Transportation is supplied to the five reception centers on the border, namely, El Centro, Calif.; Nogales, Ariz.; and El Paso, Eagle Pass, and Hidalgo, Tex.

The reception centers apply disinfection, screen and treat venereal disease, and take a 70-mm. chest X-ray of each migrant. Medical care, including hospitalization if necessary, is also provided. Since inception of the program in 1951, authorized by Public Law 78, 82d Cong., the total number processed has increased from 124,000 to more than 400,000 a year. A peak of 500,000 Mexican farm workers is anticipated for 1956.

About 3 percent of the applicants were rejected in 1955 at migratory stations and half as many more at the reception centers. The X-ray

tine Branches, Agricultural Research Service, United States Department of Agriculture. Changes in farming and irrigation practice, he said, have multiplied the possibilities of exposure of livestock to the larval form (*Cysticercus bovis*) of the beef tapeworm (*Taenia saginata*). To determine the prevalence of the parasite in humans, especially ranch and farm laborers, he recommended laboratory examination of stool specimens, as clinical symptoms of tapeworm often are vague. He specified microscopic examination of three daily stool specimens, run through a sieve and centrifuged or floated with a concentrated salt solution.

Exposure of the American public may be judged by the following facts: About 65 percent of the beef consumed in the United States is examined by inspectors of the Federal Meat Inspection Service. The records indicate that, in 1912, of the cattle inspected 0.14 percent were infested with *C. bovis*. In 1930, the percentage was up to 0.37. In 1945, it was 0.6. From 1951 through 1955, the nationwide occurrence of *C. bovis*, as indicated by the number of carcasses ordered to be retained for treatment by freezing, was at a rate that declined from 0.142 to 0.073. In Arizona, the rate has declined from 4.5 in 1945 to about 0.5 in recent years.

Such percentages are little consolation to the cattle owner who may encounter an outbreak in a cattle feed lot. Such an outbreak may result from careless disposal of the feces of a single carrier. And if the cattle do not undergo inspection at time of slaughter, the hazard may be transmitted to eaters of raw or lightly cooked meat.

In 1955, inspectors at a slaughterhouse found more than two-fifths of a single herd of 1,980 cattle, pastured and pen fed in Arizona, were infested, 16 so heavily that they had to be condemned. The other infested cattle were held for freezing, at a substantial loss to the rancher.

C. bovis in beef cattle has been associated with fecal fields used subsequently for pasture; with irrigation of pastures by primary sewage effluent; with ground feed from

freight cars contaminated by transient laborers; and with direct contamination of irrigation ditches by ranch workers.

South African studies indicate that pastures may remain infective for as long as 2 years after deposition of *C. bovis*. Other studies, however, have found infections without indication of a probable source.

Research in the field now seeks to determine accurately the age of *C. bovis* cysts found in bovine muscle; how soon such cysts may be found after ingestion of viable eggs; at what age such cysts are infectious; and, if possible, methods to improve control of the parasite.

A critical but relatively simple step in such control, Miller concluded, is the diagnosis and treatment of human carriers of *T. saginata* by physicians and public health agencies, especially in the neighborhood of pastures or feed lots. Another basic step is comprehensive inspection of meat slaughtered for market. In addition to providing privies, latrines, or other suitable facilities for hired hands, Miller emphasized, cattlemen should refrain from employing raw sewage for irrigation of pastures and should support programs to develop sanitary habits by education.

Brucellosis Control Gains With Vaccine

Veterinary services to public health in southern California were outlined by J. E. Stuart, chief, division of animal husbandry, California State Department of Agriculture.

Since 1940, all counties in the State have been classified as having less than 0.5 percent tuberculosis. Total herds which number more than 56,000, with a total of more than 3,500,000 head, have been tested. Actual tests show that reactors in recent years have amounted to less than 0.2 percent. About 650,000 cattle in 17,000 herds are tested annually by veterinarians employed in the agriculture departments of California and the Federal Government.

California's program for brucel-

losis control consists of requiring vaccination of female dairy calves. Vaccination of other calves is offered but not required. Since this program began, in 1948, more than 2,400,000 calves have been vaccinated, one-third on a voluntary basis. The aim is eventually to have herds consist wholly of vaccinated animals. About 9 of every 10 head in the State now have been vaccinated.

Infection in State dairy cattle has been reduced in 8 years from 18 percent to less than 5 percent. More than half of the herds are completely negative, on the basis of a milk ring test conducted last year with a mobile laboratory. The national goal is a rate of infection of less than 1 percent, with infection present in less than 5 percent of the herds.

Movement of dairy cattle, except for slaughter, is forbidden by the State unless the cattle test negative or have been vaccinated. The State furnishes desiccated strain 19 for vaccination without cost, and pays accredited veterinarians for doing the vaccinating.

A voluntary brucellosis program is applied to swine.

Following the 1952 outbreak of vesicular exanthema, as a preventive measure, a cooking program was inaugurated and since November 1955 all garbage fed to hogs has been cooked. Incidental effects of this program, which includes other sanitation measures, has been to reduce the hazard of trichinosis, reduce fly breeding, and reduce rat breeding. Outbreaks of vesicular exanthema have been reduced from 49 in 1954 to 15 in 1955. It is believed the cycle of this disease has been broken in California.

Other zoonoses commented upon by Stuart included anthrax, ornithosis, salmonellosis in turkey flocks, tapeworm, and rabies.

Lettuce Pickers Try Sanitation on Wheels

Opportunities for improving sanitation among harvest workers were described by Edward W. Munson, director of sanitation in California's

spread of the epidemic by personal contact. Children played freely in the garbage storage and overburdened toilet and shower rooms.

In the laundry rooms, the rinsing of soiled diapers proceeded while children were being washed, sometimes in the same tub. The 27 toilets were used by more than 400 individuals of whom more than 160 were not yet 10 years old. Many trailer residents also used chambers and charged their children with the duty of disposing of the contents, a duty they performed somewhat whimsically. Often the children emptied chambers into laundry tubs and neglected to flush them. Children rarely washed their hands after emptying the chambers.

Those infected by *Shigella* could not be isolated. The abundance of flies and the lack of screening also encouraged propagation of the infection.

The report concluded that trailer court operators should be helped to overcome conditions which tend to make the villages an incubator of infections, that legislation enacted by the State would help to strengthen health department authority with respect to housing in trailer camps, and that all public health services should be applied to help residents of trailer villages shoulder their responsibilities.

After the report was written, other outbreaks of a similar nature were reported in other trailer courts within the county jurisdiction. These outbreaks also occurred in trailer courts having a large number of children with consequent overcrowding and misuse of the community toilet and laundry facilities.

Nurse Recommends Democratic Tactics

To illustrate practical techniques in an educational campaign for implementing community health programs, Hazel Shortal, public health nursing consultant, Region 9, San Francisco, described hypothetical situations.

"Successful and sustained efforts to reduce the maternal and infant

deaths," she said, "would depend on improving the care of mother and child through adequate food, education, and medical and nursing care during pregnancy and infancy.

"Let us develop two widely different plans. In the one instance, let us say that it is decided that quick action is necessary and therefore a team of experts will be sent to the community, responsible for the organizing, directing, and operating on a demonstration basis a program of improved care for mothers and children. The team will bring the materials, supplies, and moneys. Thus equipped, changes can readily be accomplished, and success assured. Meetings will be called for the purpose of informing the people of the services that have been brought to them. Local people will be expected to respond to this generous effort of the government, and soon the experts will observe gratifying results.

"In the other instance, representatives from the Ministry of Health sent to the community will seek out the leaders in the various local groupings. The facts of maternal and infant mortality in the community will be discussed. Efforts will be made to gain the understanding of these leaders in regard to the problem, and to give the Ministry representatives something of local attitudes and behavioral patterns. Plans will be developed only after the local leaders accept their role in arriving at a solution of the problem. A service for mothers and babies will be established when the community decides that this is desirable. The Ministry will supply medical and nursing participation in the service upon request of the community. Local leaders announce the plan.

"Approval of the project by the local padre is signified by his offering physical facilities for holding clinics. Midwives will participate in the clinics by offering assistance to patients in preparing for the physical examination. The *curandero* will interpret reactions and attitudes to the physician, and, in turn, the medical recommendations to the patients. The physician and nurse will spend time with all concerned after the clinic sessions answering ques-

tions and increasing their knowledge of cultural settings in the community.

"When the problem of a more adequate diet is realized, this community itself will make the determination that help is needed and ways will be explored for effective implementation of a farm improvement program. When the community sees opportunities for initiating health practices through the schools and perceives the value of the educated person as a contributor to improved living in the community, adequate support of school programs can be expected.

"In both settings the stated objective may be reached; that is, reduction of infant and maternal deaths.

"The first situation may even eventually be taken over with local community sponsorship, but the planning described cannot be said to stimulate local interest, and the likelihood of the program surviving the stay of the team experts is not great. In the second instance, in which each step in the development of the program was a local decision and supported by responsible local leaders, only technical guidance was needed from the Ministry representatives. Pride in development and responsibility for action rested with the local groups. Satisfaction in a job well done will be sensed by the local people as well as the representatives of the Ministry."

Handicapped Children Need Coordinated Services

In an effort to guide growing communities in the development of services for children, Dr. Marcia Hays, chief of the bureau of crippled children's services in the California State Department of Health, reviewed early American practice as she outlined requisites for initiating coordinated services locally. She told how Americans first attempted to aid handicapped children by bringing them to medical centers, where they received the most expert medical attention the department could provide.

"Often because of the chronicity of the disability or infection, the incon-

screening resulted in rejection of 1.1 percent of the applicants. More than half of these are in the minimal stage of tuberculosis, a few far advanced.

Reception Centers Screen Migrants

Dr. Victor Ocampo Alonzo of Mexicali, health officer for Baja California, reviewed operations of the agreement between the United States and Mexico at reception centers. He pointed out that workers rejected for reasons of health put an unanticipated burden on the cities where they are sent for repatriation. He observed also that the arrival of large numbers at the reception centers creates health hazards when there is a lack of facilities and organization to provide for them.

While he acknowledged that many workers rejected at the placement centers should have been stopped at the Mexican migratory center, he observed also that many migratory workers, found fit at the migratory center, are likely to suffer en route from lack of sanitation or lack of consideration given to the transportation of workers by railroad or highway. He spoke of movement of workers without toilet facilities or drinking water. For lack of nourishment, he said, many arrived in a starving condition, easy prey to acute communicable disease, exposed to sunstroke in summer and to freezing in winter.

Management of migration has improved, however, to the extent that the number of wetbacks or wire-jumpers has declined from 565,000 in 1951 to 20,000 in 1955.

Investigation of Diarrhea In a Migrant Labor Camp

A report of an epidemiological investigation of shigellosis in an Arizona migrant farm labor camp in which *Shigella* was recovered from flies and feces deposited on the ground was offered by Paul J. Coleman, M.D., epidemiologist, and Paul P. Maier, M.P.H., sanitary engineer, of the Phoenix (Ariz.) Field Station,

Communicable Disease Center, Public Health Service.

During the period November 15-30, 1955, 13 individuals from 3 households in a camp of approximately 100 inhabitants were hospitalized. Since all 3 families gave histories of illness prior to arriving at the camp, opportunity for intrafamilial spread existed. *Shigella* was isolated from 8 of the patients and, during the normal population survey of the workers, from the operator of a chuck wagon who served workers in the field. *Shigella* was isolated from 7 of 37 fly pools (18 percent) and from 9 of 36 (25 percent) of cultures obtained from fresh deposits of human feces on the ground.

All organisms typed were *Shigella flexneri* 3, which was the only pathogenic organism isolated during the investigation. The history of one affected family suggests that the original infection may have been carried from Seattle, Wash., to Arizona. Environmental conditions in the camp were conducive to the high fly population, and these vectors probably contributed substantially to the mild cases and subclinical infections reported from other inhabitants of the camp.

Curb Diarrheal Deaths In Texas Infants

In 1948, it was noted that six counties in Texas contributed less than one-fifth of the live births but almost half of the deaths from infant diarrhea.

Ruby M. Lee, R.N., M.A., public health nursing consultant, Texas State Health Department, said Texas has reduced infant mortality because it expanded educational activities of organized health services, increased sanitation work, and established additional well-child conferences and nursing services with the assistance of many public and voluntary agencies.

Among specific measures employed, a public health nurse visited each home where a midwife delivery was reported on a birth certificate. These visits directly increased attendance at well-child conferences, and severe diarrhea incidence in

infants subsequently declined. The counties which formerly contributed half of the deaths from infant diarrhea now contribute a fourth.

Further reduction, Lee reported, would depend on early case finding, prompt diagnosis, early initiation of medical and nursing care, and education.

(In one of these counties, experimental fly control programs conducted by the Public Health Service contributed to reducing the mortality from infant diarrhea for the period under study.)

Lee reported that the number of pit privies in one city was reduced from 2,500 to 15, by a concerted drive, but that a new annex subsequently increased the number to 600.

Shigella Finds Ideal Environment

That Mexican migrants are not the only members of the mobile population in need of protection and health education was the implication of a report by Don Suggs, public health engineer, Los Angeles County Health Department, on an epidemic of shigellosis in a trailer village. Among residents of this village, at the time of a survey, craftsmen were predominant, followed by service workers, professional and white collar workers, and the semiskilled. Only three were classed as laborers and one resident was from the United States Army.

More than a third of the residents had been there less than 2 months, but nearly a fifth had been in residence a year or more, a few for more than 5 years.

Despite intensive efforts of the health department, two separate *Shigella* epidemics occurred in the trailer village within a period of 8 months.

Food and water supplies were free from contamination at the point of delivery. Running water was supplied each kitchen sink. Water flush toilets and sewer-connected laundry facilities were available in two community buildings. Very few of the trailers had individual toilets.

Nevertheless, the premises, heavily populated with children, favored

The drive is in charge of the National Commission for the Eradication of Malaria, presided over by the Secretary of Health and Welfare. Technical assistance is provided by the World Health Organization, and the United Nations Children's Fund will contribute insecticides and equipment. The main financial contribution, 150 million pesos for personnel, comes from the Government of Mexico.

Tuberculosis Control South of the Border

Dr. Fidel Perez Servin described services in the tuberculosis clinic of Ciudad Juarez, Chihuahua, which provides screening, observation of doubtful cases, and treatment. The major difficulty faced there is control of the ambulatory patient. As a rule, such patients need to work to support their families, under conditions which prevent them from ob-

serving prophylactic instructions even if they are so inclined.

Dr. B. Aranda Reyes described services of the phthisiology department of the Federal Department of Public Works hospital in Mexicali Valley, Baja California, which, he said, had the highest tuberculosis mortality in the country, 12.6 deaths per 10,000 inhabitants. Screening and hospitalization services are limited by the fact that patients cannot afford the expense of a trip to the center and by the shortage of available beds.

Where Aegypti Persists, Yellowjack Threatens

Dr. J. Austin Kerr, special expert in yellow fever and related virus diseases, Pan American Sanitary Bureau, Washington, D. C., reviewed events stemming from the epidemic of yellow fever which began in 1948 in Central America. Yellow fever

had been limited to the jungle there, because *Aedes aegypti*, the urban carrier of the virus, had been eliminated from the towns.

However, as the infection moves north through the jungle, leaving a trail of dead monkeys, it is expected to enter the Mexican states of Chiapas, Tabasco, and Veracruz, where *A. aegypti* may pick it up.

The presence of this mosquito species in large areas of the United States and Mexico, he reminded his audience, may trigger an explosive epidemic of yellow fever. Although the last fatality from this disease in either country was recorded in 1924, Kerr pointed out that, thanks to rapid modern transportation, a person with the disease still in incubation may arrive in Houston, New Orleans, Progreso, or Merida any time. If *aegypti* mosquitoes find the patient before the health department does, infection, panic, and disorganization of the community may be expected, all for the lack of species eradication.

PHS Staff Appointments

Jack Masur, M.D., became director of the Public Health Service Clinical Center, National Institutes of Health, Bethesda, Md., on November 1, 1956. At the time of his appointment he was chief of the Bureau of Medical Services.

From 1948 to 1951 Dr. Masur supervised the planning and building of the center—the largest facility of its kind in the world—which officially opened in July 1953. Before joining the Public Health Service in 1943, he was assistant director of Montefiore Hospital, New York City, and executive director of Lebanon Hospital, also in New York City.

John W. Cronin, M.D., is the new chief of the Bureau of Medical Services. The bureau administers Public Health Service hospitals, programs for Indian health and foreign quarantine, surveys of dental and nursing resources,

and grants for construction of hospitals and rehabilitation facilities under the Hill-Burton Act and amendments. As chief of the Hospital and Medical Survey and Construction Program from 1949 until his appointment, Dr. Cronin had the responsibility for administration of the grants program.

Vane M. Hoge, M.D., first director of the Hospital and Medical Survey and Construction Program, will assume administration of the Hill-Burton program in addition to his duties as associate chief of the Bureau of Medical Services.

Donald W. Patrick, M.D., director of the Clinical Center until Dr. Masur's appointment, has been appointed medical officer in charge of the Public Health Service hospital at San Francisco.

venience of transportation, and the lack of services in the home community, a child remained in the center 1, 2, or 3 years. The family reorganized its life without their child, and the child grew without a family. And then abruptly when we felt our work was done, the child was discharged and returned to what had been his home. But this was not the same child to his family, and they were not the same family to the child, and what we called 'the adjustment' was slow, painful, and confusing to both the child and the family. Sometimes it would not be made, and so, as in more than one instance, we found the child later in the State school for delinquents. So our first approach, based on a well meaning desire to place fine medical care above everything else, was muddled.

"Now in the development of services we are guided by a principle which has become as important as fine medical care: We say that the child is first a child in his family and he belongs at home. Where it is not possible to plan his care so that he may be at home, we bring parents and child together as often as possible, and we limit the time away from home so that separation cannot be established . . .

"Children need coordinated services in the home community, or reasonably nearby. To initiate them, neither definitive specialization nor the ultimate in buildings and equipment is a necessity. Good core services, built around perhaps a graduate physician and a qualified teacher—each with an understanding of parents and children, their needs and pattern of growth—should be the first step. And once these are established, attracting other disciplines and specialized skills to the community becomes a matter of proper timing."

Sociologist Discusses Cultural Factors

Lyle Saunders, associate professor of preventive medicine and public health at the University of Colorado School of Medicine, called

attention to cultural factors that complicate the work of health agencies in border agricultural areas. Differences in social origin and cultural conditioning between professional and technical personnel and members of the public they serve hamper communication and make difficult the coming to agreement on health goals and the means for reaching them.

Cooperation across an international border, Saunders suggested, is further complicated by differing administrative philosophies, political traditions, governmental systems, and by a disparity in economic resources. He urged that public health agencies seek the collaboration of social scientists on programs where cultural or subcultural differences may be hindering factors.

Penicillin Prevents *Neisseria gonorrhoeae*

The question of resistance of *Neisseria gonorrhoeae* to penicillin has been raised by physicians who have found positive smears taken from prostitutes who have received weekly doses of the antibiotic.

Dr. Mariano Curiel Aleala, chief of the venereal disease control program in Mexicali, Baja California, noted that injection of 300,000 international units of aluminum monostearate penicillin assures blood levels of the drug effective against *N. gonorrhoeae* for 96 hours. As the incubation period is generally 72 hours, weekly injections of that dose are assumed to be effective in preventing the disease.

Braulio B. Ramirez of the Institute of Hygiene, Mexicali, reported use of a medium of agar and cactus gum to culture 100 samples of cervical secretions from prostitutes under prophylactic control. Smears were taken from the colonies. Each of the subjects had taken 300,000 international units of aluminum monostearate penicillin weekly for at least 3 weeks before the test.

All but one culture were negative. The smear taken from the one positive culture was negative. He concluded that *N. gonorrhoeae* is not

resistant to penicillin as applied by the department to prostitutes for months or even years.

Poliomyelitis Surveillance Pursued in Mexico

A report of a 1955 outbreak of poliomyelitis in Mexicali, Baja California, by Dr. Jose Reyes Ruiz, epidemiologist, Baja California State Health Department, stated that all of 24 cases reported occurred within the first 3 years of life. This evidence coincided with findings of an extensive epidemiological survey by Dr. Carlos Calderon and others in the Federal Department of Health in Mexico, who stated that from 1945 to 1954, 93 percent of the poliomyelitis patients identified were less than 5 years of age.

Calderon's report found a higher incidence of paralytic cases in families of very low income than in families of acceptable or good monthly income, 1.75 against 1.1 per 1,000 families. Differences in family sizes were not reported. The finding, contrary to experience in other countries, is attributed to crowding, on the ground that the infection is assumed to be a consequence of person-to-person contact.

Eight-Year Campaign To Wipe Out Malaria

On the premise that limited DDT applications may encourage the rise of resistant malaria vectors, Mexico has launched a drive which is intended to eradicate malaria in 8 years and to maintain a surveillance system to prevent reinfection of carriers.

Dr. Manuel E. Pesqueira, Sub-Secretary of Health of Mexico, stated that, at present, malaria is found in three-fourths of Mexican territory, with 16 million inhabitants. Malaria parasites, third cause of death in the nation, produce fevers in about 2 million patients, with a mortality of more than 1 percent. The disease is most common in the Tehuantepec Isthmus.

The drive is in charge of the National Commission for the Eradication of Malaria, presided over by the Secretary of Health and Welfare. Technical assistance is provided by the World Health Organization, and the United Nations Children's Fund will contribute insecticides and equipment. The main financial contribution, 150 million pesos for personnel, comes from the Government of Mexico.

Under "on site" conditions, direct inoculation into cold untempered media of contaminated samples of sea water, followed by incubation 5 to 6 hours later, is a satisfactory technique for routine bacterial analyses.

Evaluating Bacterial Contamination in Sea Water Samples

By GERALD T. ORLOB, M.S. in C.E.

IT IS APPARENT that interpretation of the significance of bacterial analyses obtained during surveys of sewage pollution of sea water must be tempered with the realization that many factors influence their reliability. Not the least of these factors is the effect of bacterial die-away or regrowth during the period between sample collection and laboratory analysis.

Standard procedures for the bacteriological analysis of water samples usually recommend that inoculation be carried out as soon after collection as practical and that if storage is necessary the temperature should be kept between the limits of 0° C. and 10° C. Unfortu-

nately, because many sites under survey are remote from adequate laboratory facilities, storage during transportation becomes essential. Needless to say, refrigeration, though desirable, is not always convenient or practical. In the routine practice of public health and pollution control agencies charged with the bacteriological analysis of contaminated waters, delays of 5 to 6 hours are not uncommon. Often storage of samples overnight may be necessary (even though not the preferred procedure) in some overworked laboratories.

Delays or failure to provide refrigeration may significantly influence the results of individual analyses and, consequently, invalidate certain conclusions which might be drawn from the aggregate of results from a certain water under survey. If the water being investigated is that of an ocean bathing beach, the results of analysis may be close to worthless.

Mr. Orlob, assistant professor of civil engineering at the University of California, performed the investigative work represented by this paper during the 3½ years he was in charge of water pollution and industrial waste surveys for the State of Washington Pollution Control Commission. Author of 14 reports and papers covering these investigations and of additional research reports associated with water reclamation, he is engaged at present in a fundamental study of the factors influencing the movement of bacteria in underground water. The project is sponsored by the Public Health Service.

Extent of Coliform Die-Away

The population of the coliform group of bacteria, the common presumptive indicator of domestic sewage contamination, is frequently subject to drastic change during the early hours of its exposure to a new and foreign environment. A review of available literature on the subject of survival of enteric bacteria in sea

water (1, 2), reveals a few sources of information as to the extent of early die-away or growth in sea water samples.

For example, the experiments of Beard and Meadowcroft (3) indicate *Escherichia coli* mortalities in the waters of San Francisco Bay of about 68 percent in 0.8 days and 90 percent in 3.5 days.

Ketchum and his associates (4), and later Vaccaro and his co-workers (5), showed reductions of *E. coli* inoculations as great as 90 percent in raw Vineyard Sound water stored for 24 hours in laboratory containers at room temperature.

Williams (6) likewise noted considerable reduction in *E. coli* inoculums in natural sea water stored in the laboratory. He reported an average mortality of 90 percent in 25 hours. In samples of sewage suspended in dialysing tubing in the natural environment the coliform group of organisms suffered a 90 percent mortality in 25 hours although in a few cases growth was experienced.

Nusbaum and Garver (7) observed high mortalities of coliforms in laboratory tests, as great as 65 percent in 24 hours, but generally they noted growth rather than die-away in dialysing tubing suspended in San Diego Bay. Coliform survival curves representative of the observations of several of these investigators are shown in the figure.

Several experiments of mine on samples taken from Elliott Bay, Wash., near a large outfall discharging untreated sewage, showed mortalities up to 74 percent in 8 hours of storage. In experiments with a water sample taken from Budd Inlet, a salt water branch of Puget Sound which forms the harbor for Olympia, Wash., coliform die-away was 56 percent in 10 hours at a storage temperature of 20° C. A similar sample held for the same period at 3° C. showed a 38 percent reduction in coliform population. Samples prepared from dilutions of settled sewage and Pacific Ocean water collected off San Francisco showed mortalities as great as 92 percent in 24 hours at 30° C. and 68 percent at 21° C., with no significant change at 5° C.

The presence of organic nutrients may tend to offset bacterial die-away, but without refrigeration growth may occur in the early hours

of storage. For example, the addition of lactose broth to a series of samples stored at 20° C. resulted in large increases in population during the first 24 to 48 hours of storage. A period of rapid die-away followed, but die-away occurred only after a substantial lag period. The magnitude of the initial rise, the length of the lag period, and the time for 90 percent mortality were all directly proportional to the concentration of nutrient added. The survival curve for one of these tests (120 p.p.m. lactose broth) also is shown in the figure along with the results of other experiments.

Die-Away Formulation

The figure illustrates certain similarities among the coliform survival curves obtained by different investigators. For example, each curve shows a characteristic logarithmic decrease phase with a slightly varying slope. Several curves, especially those in which growth occurred in the early stages of exposure, show a lag period before the onset of logarithmic decrease. And those experiments for which the data are sufficiently extensive indicate a resistant phase exemplified by a decreasing rate of decrease and the survival of a few coliforms for comparatively long periods of time. The decrease in bacterial numbers after an initial lag is perhaps best expressed by Chick's law (8, 9), which may be written in the following form:

$$\frac{N}{N_0} = 10^{-k(a-t_0)}$$

N is the number of survivors after time t , in days; N_0 is the initial bacterial population; t_0 is the lag period before logarithmic decrease, and k is a constant.

Field Inoculation Technique

The State of Washington Pollution Control Commission, with due concern for the validity of bacteriological survey results on ocean and brackish waters, has adopted the practice of field inoculation at the site of sample collection in an effort to minimize bacterial die-away or multiplication during transport to the laboratory. This procedure, of necessity, requires that the inoculation be made directly into cold un-

Coliform Survival in Sea Water Samples

tempered media and that the inoculated tubes suffer the delay between sample collection and incubation normally experienced by the raw sample. This practice, while not representing the ideal condition for the preservation of the original bacteria in a viable state, does provide a better chance for an analysis truly representative of "on site" conditions.

The constant k , sometimes referred to as the coefficient of death rate, is indicative of the rate of bacterial die-away. It may be expressed as the reciprocal of the time in days required to achieve a 90 percent mortality of the initial number of bacteria when due account is taken of the initial lag period. It is generally greatest at high temperatures and during the summer months. Typical values of k range from about 0.3 (Beard and Meadowcroft, see figure) to 1.6 (my experiments at Elliot Bay, see figure). The majority of values fall between the limits 0.6 and 1.2.

The significance of the coefficient of death rate in terms of bacterial die-away during sample storage is best illustrated by a simple example. If it is assumed that k has an average value of 1.0 and that there is no appreciable lag, the number of coliforms remaining after 6 and 24 hours' exposure would be, according to the equation, respectively, 56.3 percent and 10 percent of the original population.

If a lag period occurs, the sample usually experiences some growth rather than a decrease in population. In either case the bacteriological analysis, unless performed immediately at the site of sample collection, will yield unsatisfactory results. The obvious advantages of refrigeration, where it can be conveniently employed to suppress both bacterial growth and bactericidal activity, cannot be depreciated. It must be acknowledged, however, that under conditions of routine sample collection adequate refrigeration is not readily available. Moreover, when the bactericidal effect of sea water is strong, refrigeration may be somewhat less than satisfactory.

To determine whether or not a preliminary period of 5 to 6 hours in cold media would have any appreciable effect on the viability of bacteria, we compared the cold media inoculation procedure statistically with the tempered

media inoculation procedure representative of the best possible practice.

First, from a single sample of settled sewage diluted 1:2,500 in tap water, we prepared twenty 1:10 dilutions in sterile water. Then, we divided the 20 samples into 2 groups of 10 each in order of initial inoculation, placing the odd numbers in group A and the even numbers in group B.

Working alternately from one group to the other, we inoculated all 20 samples according to the standard inoculation procedure and completed the test by confirmation on brilliant green bile broth. All inoculations consisted of five 1-milliliter portions in each of at least 3-decimal dilutions.

Table 1. Comparison of tempered media and cold media inoculation techniques

Sample ¹	Most probable number coliform organisms per 100 ml.	
	Group A ²	Group B ³
1-----	3,300	1,700
2-----	7,900	2,300
3-----	3,300	3,300

Standard deviation-----	1,910	1,170

¹ 1:2,500 dilution of settled sewage in tap water.

² Inoculated immediately into tempered media (37° C.) and incubated.

³ Inoculated immediately into cold media (23° C.). Stored 6 hours at 23° C., then incubated.

We analyzed group A samples in standard strength lactose broth tempered to 37° C. before inoculation, and immediately after inoculation placed the samples in the incubator.

We examined group B samples in the same media but at a temperature of 23° C., and then stored the samples for 6 hours at the same temperature before incubating them at 37° C.

The results of this experiment (table 1) revealed no significant difference between the two procedures. In fact, the spread in individual

Coliform Survival in Sea Water Samples

⁴ No significant difference.

⁵ Significantly different.

⁶ Significant difference questionable.

od. We inoculated each sample after storage into tempered media, and then incubated it in the customary fashion. We used 5 portions of decimal dilutions from each sample to determine the most probable number (MPN) of coliform organisms per 100 ml. of the original sample. A summary of the results of these tests is given in table 3.

These experiments indicate that bacterial numbers may change during storage, even for comparatively short periods, may seriously affect the interpretation of survey results. It is particularly significant that, even though one series (series D) of samples was refrigerated, an appreciable reduction in bacterial numbers occurred in this series. As we expected, the least population change occurred in the portion of the original sample that was stored at normal air temperature before inoculation. This observation is in accord with the results of long-range studies performed on Pacific Ocean water collected near San Francisco in which higher rates were observed to be directly proportional to temperature, and refrigeration was found to induce an appreciable lag prior to die-off (2).

Application of the "null hypothesis" (10) in testing the significance of the differences in values given in table 3 indicates a comparatively small probability that the differences between the mean of the control series A and the mean of either series C or series D could have resulted from chance alone. However, when this statistical test is used to com-

pare series B, the cold media inoculations, with the control series (series A), the difference is not statistically significant. It is readily apparent that when the bactericidal effect of sea water is high a comparatively short delay in inoculation into media, even cold media, may produce a much different picture of contamination than that actually existing at the time of sampling. Even refrigeration of the samples may not be sufficient to arrest bactericidal action although this practice is undoubtedly much superior to storage of the sample at normal air temperatures.

Summary and Conclusions

Changes in populations of coliform bacteria in contaminated sea water during the early hours immediately following collection of the sample may have a significant bearing on the interpretation of the results of bacteriological surveys. Refrigeration of samples, although generally recommended when extended storage of samples is necessary, is not always capable of minimizing the bactericidal effect of sea water. Direct inoculation of the sample into cold media at the sampling site, with a 5- to 6-hour delay in incubation, produces results which are generally comparable with direct inoculation into tempered media followed by immediate incubation. This method is used by the State of Washington Pollution Control Commission and is recommended for general use on bacteriological surveys of sea water.

observations indicated by the standard deviation from the mean was actually less, though not statistically significant, in group B (cold untempered media) than in group A (tempered media).

To illustrate the effect of short-term changes in bacteria populations in sea water samples and to test the applicability of several storage and handling techniques, we conducted a special series of experiments during an actual bacteriological survey of Budd Inlet, Wash.

We made 14 examinations of the coliform content of the water near a single survey station off the port of Olympia, Wash., from September 1951 through May 1952.

The samples were collected under the wide variety of conditions that would be encountered on any routine field survey. The harbor at Budd Inlet received the untreated sewage discharge from the city of Olympia throughout the 9-month survey period. In addition, the inlet provided the egress for runoff of an extensive area drained by the Deschutes River. A combination of runoff, waste discharge, tidal fluctuation, and climatic variations provided

considerable variety in salinity, temperature, amount of dissolved oxygen, and organic content. A summary of individual survey observations is presented in table 2.

We examined each of the samples collected at the survey station by four distinctly different procedures. Immediately after collection of the sample, an inoculation was made into tempered (37° C.) lactose broth as well as into cold media. The temperature of the cold media was close to that of the surrounding air (13°-23° C.). The tempered media series (series A) was incubated without further delay at 37° C. and served as a control for evaluation of the other techniques. The samples in the cold media series (series B) were held at air temperature for periods ranging between 5 and 6 hours before inoculation into tempered media, then incubated at 37° C. The samples in the cold media series (series C) were held at air temperature for 5 to 6 hours, and then inoculated into tempered media, then incubated at 37° C. The samples in the cold media series (series D) were refrigerated at 6° C. for a

A Digest of State Enabling Legislation for Mosquito Abatement Through 1955

PHS Publication (unnumbered).
1956. 83 pages.

This publication covers the laws on mosquito abatement in existence in 24 States. It is intended to provide the basis by which State and local groups responsible for such activities can evaluate or compare their existing legislation or acquire the context and terminology for drafting new legislation; to provide the procedures for initiating, directing, and operating a program; and to provide Federal and State officials with basic information for planning and coordinating these activities.

The codification for each law includes the following: legislative history, authorization and procedures for formation, boards of control and their powers and duties, guidance and coordination, finance,

ing, annexation, consolidation, and penalties. Also included in the publication is a summary table on financing.

Copies of this booklet can be obtained from the Communicable Disease Center, Public Health Service, Atlanta 23, Ga.

Careers in Mental Health

PHS Publication No. 23. Revised 1956. 19 pages; illustrated. 20 cents.

The 1956 revision of this pamphlet lists the current level of stipends available under Public Health Service traineeships for individuals training in psychiatry, psychiatric nursing, clinical psychology, and psychiatric social work. The pamphlet describes general professional opportunities in the mental health field and contains information about training opportunities for such employment.

Each major professional area is

described, and the horizons for personal and professional development are outlined. Listed are the qualifications, educational requirements, and potential earnings. The pamphlet tells where additional information about each profession and necessary course of study may be obtained.

The pamphlet is intended for high school and college students who are planning a career and are interested in working with people. It is also useful for guidance and counseling personnel.

This section carries announcements of all new Public Health Service publications and of selected new publications on health topics prepared by other Federal Government agencies.

Publications for which prices are quoted are for sale by the Superintendent of Documents, U. S. Government Printing Office, Washington 25, D. C. Orders should be accompanied by cash, check, or money order and should fully identify the publication. Public Health Service publications which do not carry price quotations, as well as single sample copies of those for which prices are shown, can be obtained without charge from the Public Inquiries Branch, Public Health Service, Washington 25, D. C.

The Public Health Service does not supply publications issued by other agencies.
